ENCYCLOPÆDIA BRITANNICA;

OR, A

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE;

Conſtructed on a PLAN,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digeſted into the FORM of Diſtinct
TREATISES OR SYSTEMS,
COMPREHENDING
The HISTORY, THEORY, and PRACTICE, of each,
according to the Lateſt Diſcoveries and Improvements;
AND FULL *EXPLANATIONS* GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the moſt important Topics relative to RELIGION, MORALS,
MANNERS, and the OECONOMY of LIFE:
TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General HISTORY, *Ancient* and *Modern*, of the different Empires, Kingdoms, and States;
AND
An Account of the LIVES of the moſt Eminent Perſons in every Nation,
from the earlieſt ages down to the preſent times.

Compiled from the writings of the beſt Authors, in ſeveral languages; the moſt approved Dictionaries, as well of general ſcience as of its particular branches; the Tranſactions, Journals, and Memoirs, of learned Societies, both at home and abroad; the MS. Lectures of Eminent Profeſſors on different ſciences; and a variety of Original Materials, furniſhed by an extenſive Correſpondence.

THE THIRD EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

VOL. XIII. NEH — PA

INDOCTI DISCANT, ET AMENT MEMINISSE PERITI.

Nehemiah.

NEHEMIAH, or Neemias, ſon of Hachaliah, was born at Babylon during the captivity, (Neh. i. 1, 2, &c.) He was, according to ſome, of the race of the prieſts, but, according to others, of the tribe of Judah and the royal family. Thoſe who maintain the firſt opinion, ſupport it by a paſſage in Ezra, (x. 10.) where he is called a prieſt; but thoſe who believe that he was of the race of the kings of Judah, ſay, 1ſt, That Nehemiah having governed the republic of the Jews for a conſiderable time, there is great probability he was of that tribe of which the kings always were. 2dly, Nehemiah mentions his brethren Hanani, and ſome other Jews, who coming to Babylon during the captivity, acquainted him with the ſad condition of their country. 3dly, The office of cup-bearer to the king of Perſia, to which Nehemiah was promoted, is a further proof that he was of an illuſtrious family. 4thly, He excuſes himſelf from entering into the inner part of the temple, probably becauſe he was only a laic, (Neh. vi. 11.) "Should ſuch a man as I flee? And who is there that, being as I am, would go into the temple to ſave his life?"

The Scripture (Ezra ii. 63. Nehem. vii. 65.) calls him תרשתא *tirſhatha*, that is to ſay, "cup-bearer;" for he had this employment at the court of Artaxerxes Longimanus. He had an exceeding great tenderneſs for the country of his fathers, though he had never ſeen it; and one day, as ſome Jews newly come from Jeruſalem acquainted him with the miſerable eſtate of that city, that its walls were beat down, its gates burnt, and the Jews were become a reproach among all nations; he was ſenſibly affected with this relation; he faſted, prayed, and humbled himſelf before the Lord, that he would be favourable to the deſign he had then conceived of aſking the king's permiſſion to rebuild Jeruſalem. The courſe of his attendance at court being come, he preſented the cup to the king according to cuſtom; but with a countenance ſad and dejected; which the king obſerving, entertained ſome ſuſpicion, as if he might have had ſome bad deſign; but Nehemiah (ii.) diſcovering the occaſion of his diſquiet, Artaxerxes gave him leave to go to Jeruſalem, and repair its walls and gates: but, however, upon this condition, that he ſhould return to court at a time appointed. Letters were made out, directed to the governors beyond the Euphrates, with orders to furniſh Nehemiah with timbers neceſſary for covering the towers and gates of the city, and the houſe deſigned for Nehemiah himſelf, who was now appointed governor of Judea, in the year of the world 3350.

Nehemiah being arrived at Jeruſalem with the king's commiſſion, went round the city; and having viewed the condition of the walls, aſſembled the chief of the people, produced his commiſſion, and exhorted them to undertake the reparation of the gates and walls of the city. He found every perſon ready to obey him; whereupon he immediately began the work. The enemies of the Jews, obſerving theſe works in ſuch forwardneſs, made uſe of all the means in their power to deter Nehemiah from this undertaking, and made ſeveral attempts to ſurpriſe him; but finding that their deſigns were diſcovered, and that the Jews kept upon their guard, they had recourſe to craft and ſtratagem, endeavouring to draw him into an ambuſcade in the fields, where they pretended they would finiſh the diſpute at an amieable conference: but Nehemiah gave them to underſtand, that the work he had begun required his perſonal attendance; and therefore he could not come to them. He ſent the ſame anſwer to four ſeveral meſſages that they ſent one after another on the ſame ſubject, (*Id.* iv. and vi.)

Sanballat, the chief of the enemies of the Jews, together with his aſſociates, wrote word, that a report was ſpread that the Jews were building the walls of Jeruſalem only with a deſign to make it a place of ſtrength, to ſupport them in an intended revolt; that it was ſaid alſo that Nehemiah had ſuborned falſe prophets to favour his deſigns, and to encourage the people to chooſe him king; and to ſtop the courſe of theſe rumours, he adviſed him to come to him, that they might confer together, and take ſuch reſolutions as ſhould be found convenient. Nehemiah gave himſelf no trouble on this account, but returned for anſwer, that all thoſe accuſations were falſe and made at random. About the ſame time he diſcovered, that a falſe prophet, called *Shemaiah*, had been corrupted by his enemies, and that ſome of the chief of the city were ſecretly in confederacy with them. Yet all this did not diſcourage him: he went on with his work, and happily completed it in two and fifty days after it had been begun.

Then he made a dedication of the walls, of the towers, and of the gates of Jeruſalem, with the ſolemnity and magnificence that ſuch a work required. He ſeparated the prieſts, the Levites, and the princes of the people, into two companies, one of which walked to the ſouth and the other to the north, on the top of the walls. Theſe two companies were to meet at the temple. The proceſſion was accompanied with muſic both vocal and inſtrumental: and when they were all come to the temple, they there read the law, offered ſacrifices, and made great rejoicings. And as the feaſt of tabernacles happened at the ſame time, it was celebrated with great ſolemnity, (*Id.* viii.) Nehemiah obſerving that the compaſs of the city was too large for its inhabitants, he ordered that the chief of the nation ſhould fix their dwelling in the city; and cauſed them to draw lots, by which a tenth part of the whole people of Judah were to dwell at Jeruſalem, (*Id.* xi.) Then he applied himſelf to the reformation of ſuch abuſes as had crept into the adminiſtration of the public affairs. He curbed the inhumanity of the great ones, who held in a ſtate of ſlavery the ſons and daughters of thoſe who were poor or unfortunate, keeping their lands in poſſeſſion, which theſe poor people had been obliged either to mortgage or to ſell to the rich. Another abuſe there was, which Ezra had in vain attempted to redreſs, that they had contracted marriages with ſtrange and idolatrous women. Nehemiah undertook to diſſolve theſe marriages, ſucceeded in it, and ſent away all ſuch women as had been taken againſt the expreſs command of the law, (*Id.* ix.) Having likewiſe obſerved, that the prieſts and Levites were obliged to take refuge wherever they could, and ſo the miniſtry of the temple was not attended or performed with that decency it ought, becauſe they did not receive the revenues that the law had appointed for their ſubſiſtence; he obliged the people punctually to pay the miniſters of the Lord what was due to them, and enjoined the prieſts and Levites duly to attend on their reſpective duties, and to diſcharge their functions, (*Id.* xiii. 10, 11, &c.) He enforced the obſervation of the ſabbath, which had been much neglected at Jeruſalem, and would not permit ſtrangers to come in to buy and ſell, but kept the gates of the city ſhut all that day. And, to perpetuate as much as was poſſible theſe good regulations which he had newly eſtabliſhed, he engaged the chief men of the nation ſolemnly to renew the covenant with the Lord. This ceremony was performed in the temple, and an inſtrument was drawn up, which was ſigned by the principal men, both prieſts and people, (*Id.* ix. x.) in the year of the world 3551.

We read in the books of Maccabees, (2 Macc. i. 19, 20, 21, &c.) that Nehemiah ſent to ſearch for the holy fire, which before the captivity of Babylon the prieſts had hid in a dry and deep pit; but not finding any fire there, but inſtead thereof a thick and muddy water, he ſprinkled this upon the altar; whereupon the wood which had been ſprinkled with this water took fire preſently as ſoon as the ſun began to appear. Which miracle coming to the knowledge of the king of Perſia, he cauſed the place to be encompaſſed with walls where the fire had been hid, and granted great favours and privileges to the prieſts. It is recorded in the ſame books, (2 Macc. ii. 13, 14.) that Nehemiah erected a library, wherein he placed whatever he could find, either of the books of the prophets, of David, or of ſuch princes as had made preſents to the temple. Laſtly, He returned to Babylon (*Id.* v. 14. and xiii. 6.) according to the promiſe he had made to King Artaxerxes, about the thirty ſecond year of this prince, in the year 3563. From thence he returned again to Jeruſalem, where he died in peace, about the year 3580, having governed the people of Judah for about thirty years.

The book which in the Engliſh Bible, as alſo in the Hebrew, has the name of *Nehemiah*, in the Latin Bible is called the book of *Eſdras;* and it muſt be confeſſed, that though this author ſpeaks in the firſt perſon, and though at firſt reading one would think that he had writ it day by day as the tranſactions occurred, yet there are ſome things in this book which could not have been written by Nehemiah himſelf; for example, memorials are quoted wherein were regiſtered the names of the prieſts in the time of Jonathan the ſon of Eliaſhib, and even to the times of the high prieſt Jaddus, who met Alexander the Great. Theſe therefore muſt have been added afterwards.

It may well be queſtioned, whether this Nehemiah be the ſame that is mentioned in Ezra, (ii. 2. and Neh. vii. 7.) as one that returned from the Babyloniſh captivity under Zerubbabel; ſince from the firſt year of Cyrus to the twentieth of Artaxerxes Longimanus, there are no leſs than ninety-two years intervening; ſo that Nehemiah muſt at this time have been a very old man, upon the loweſt computation an hundred, conſequently utterly incapable of being the king's cup-bearer, of taking a journey from Shuſhan to Jeruſalem, and of behaving there with all the courage and activity that is recorded of him. Upon this preſumption, therefore, we may conclude that this was a different perſon, though of the ſame name, and that Tirſhatha (the other name by which he is called, Ezra ii. 63. and Neh. vii. 65.) denotes the title of his office, and both in the Perſian and Chaldean tongues was the general name given to the king's deputies and governors.

NEHOW, one of the Sandwich iſlands, diſcovered by Captain Cook in his laſt voyage to the Pacific ocean: they are eleven in number, and are ſituated from 18° 44′ to 22° 15′ N. Lat. and from 154° 56′ to 160° 24′ W. Long. They are not very particularly deſcribed in any account that has hitherto appeared.

NEIGHBOUR, 1. One who dwells or is ſeated near to another (2 Kings iv. 3.) 2. Every man to whom we have an opportunity of doing good (Matt. xxii. 39.) 3. A fellow labourer of one and the ſame people (Act. vii. 27.) 4. A friend (Job xvi. 21.) At the time of our Saviour, the Phariſees had reſtrained the word neighbour to ſignify thoſe of their own nation only, or their own friends; being of opinion that to hate their enemy was not forbidden by their law. But our Saviour informed them, that the whole world were their neighbours; that they ought not to do to another what they would not have done to themſelves; and that this charity ought to be extended even to their enemies (Matt. v. 43. Luke x. 29, &c.)

NEISSE, a handſome town of Sileſia in Germany, and the reſidence of the biſhop of Breſlaw, who has a magnificent palace here. The air is very wholeſome, and proviſions are cheap; the inhabitants carry on a great trade in wine and linen. This place ſuffered greatly by an inundation and fire in 1729. It was taken by the Pruſſians in 1741, who augmented the fortifications after the peace in 1742, and built a citadel to which they gave the name of *Pruſſia*. It is ſeated on a river of the ſame name, in E. Long. 17. 35. N. Lat. 50. 32.

NEIUS MONS (anc. geog.), at the foot of which ſtood Ithaca, a town of the iſland of that name, (Homer).

Nelſon.

NELSON (Robert), a learned and pious Engliſh gentleman, was the ſon of Mr John Nelſon a conſiderable Turkey merchant, and was born in June 1656. He had the firſt part of his education at St Paul's ſchool, London; but the principal part was under a private tutor in his mother's houſe, after which he ſtudied at Trinity College, Cambridge. In 1680 he was choſen a fellow of the Royal Society; being probably inclined to receive that honour out of reſpect to his friend and ſchoolfellow Dr Edmund Halley, for whom he had a particular regard, and in whoſe company he ſet out on his travels abroad the December following. In the road to Paris, they ſaw the remarkable comet which gave riſe to the cometical aſtronomy by Sir Iſaac Newton; and our author, apparently by the advantage of his fellow traveller's inſtructions, ſent a deſcription of it to Dr, afterwards Archbiſhop, Tillotſon, by whom he was very much eſteemed. Before he left Paris, he received a letter from a friend in the Engliſh court, inviting him to purchaſe a place there, by the promiſe of his aſſiſtance in it. This propoſal was made by Mr Henry Saville, brother to Lord Hallifax: he had been ſworn vice-chamberlain of the King's houſhold in December 1680, and was at this time envoy from Charles II. of the court of France; though now at London, whence he ſent this offer in a letter to Mr Nelſon; who, being but young, and having a great affection for King Charles and the duke of York, was pleaſed with the thoughts of figuring it near their perſons; but as he could not reſolve upon an affair of ſuch conſequence without the approbation of his mother and uncle, he firſt applied to Tillotſon to ſound them, with aſſurances of determining himſelf by their judgment and advice, including alſo that of the Dean: who finding them both averſe to it, he thereupon dropped the matter, and purſued his journey with his fellow traveller to Rome. Here he fell into the acquaintance of Lady Theophila Lucy, widow of Sir Kingſmill Lucy of Broxburne in Hertfordſhire, Bart. and ſecond daughter of George earl of Berkeley, who ſoon diſcovered a ſtrong paſſion for him: this concluded in marriage, after his arrival in England in 1682. But it was ſome time before ſhe confeſſed to Mr Nelſon the change of her religion; which was owing to her acquaintance with Boſſuet, and converſations at Rome with Cardinal Philip Howard, who was grandſon of the earl of Arundel, the collector of the Arundelian marbles, &c. and had been raiſed to the purple by Pope Clement X. in May 1675. Nor was this important alteration of her religious ſentiments confined to her own mind, but involved in it her daughter by her firſt huſband, whom ſhe drew over to her new religion; and her zeal for it prompted her even to engage in the public controverſy then depending. She is the ſuppoſed authoreſs of a piece written in 1686, 4to, under the title of, "A diſcourſe concerning a judge of controverſy in matters of religion, ſhowing the neceſſity of ſuch a judge."

This misfortune touched her huſband very nearly. He employed not only his own pen, but thoſe of his friends Dr Tillotſon and Dr Hickes, to recover her; but all proved ineffectual; and ſhe continued in the communion of the church of Rome till her death. She was a perſon of fine ſenſe and underſtanding. Dr Tillotſon particularly laments her caſe on that account; and even ſeems not to be entirely free from all apprehenſions of the influence ſhe might have upon her huſband in this important affair. But Mr Nelſon's religion was too much the reſult of his learning and reaſon to be ſhaken by his love, which was equally ſteady and inviolable. Her change of religion made no change in his affections for her; and when ſhe relapſed into ſuch a bad ſtate of health as obliged her to go and drink the waters at Aix, he attended her thither in 1688: and not liking the proſpect of the public affairs at home, he proceeded to make a ſecond trip to Italy, taking his lady, together with her ſon and daughter by her former huſband, along with him. He returned through Germany to the Hague, where he ſtaid ſome time with Lord Durſley, who was married to his wife's ſiſter.

From the Hague he arrived in England, in the latter end of 1691; where, being averſe to the Revolution, he declared himſelf a Nonjuror, and left the communion of the church of England. In this laſt point he had conſulted Dr Tillotſon, and followed his opinion, who thought it no better than a trick, (deteſtable in any thing, and eſpecially in religion), to join in prayers where there was any petition which was held to be ſinful. Thus, notwithſtanding their difference of opinion reſpecting the lawfulneſs of the Revolution, the friendſhip between them remained the ſame; and the good archbiſhop expired in his friend's arms in 1694. Nor did Mr Nelſon's friendſhip end there; he continued it to his grace's widow, and was very inſtrumental in procuring her penſion from the crown to be augmented from 400l. to 600l. *per annum*. It is very remarkable, that the great regard he had always ſhown to Tillotſon, added to his own reputation for learning, judgment, and candour, induced Dr Barker, who publiſhed the archbiſhop's poſthumous ſermons, to conſult our author on that occaſion. Among the manuſcripts, there was found one diſcourſe wherein the archbiſhop took an occaſion to complain of the uſage which he had received from the Nonjuring party, and to expoſe, in return, the inconſiſtency of their own conduct; remarking particularly, that, upon a juſt compariſon of their principle of non-reſiſtance with their actual non-aſſiſtance to King James II. they had little reaſon to boaſt of their loyalty to him: and yet, ſevere as this diſcourſe was upon that party, Mr Nelſon, notwithſtanding his attachment to them, was very zealous to have it printed, alleging, that they deſerved ſuch a rebuke for their unjuſt treatment of ſo good a man. However, the ſermon was then ſuppreſſed, and is now probably loſt.

Our author's new character unavoidably threw him into ſome new connexions. Among theſe we find mentioned particularly Mr Kettlewell, who had reſigned his living at Coleſhill in Warwickſhire on account of the new oaths, and afterwards reſided in London. This pious and learned divine alſo agreed with him, in leaving the communion of the eſtabliſhed church; yet at the ſame time perſuaded him to engage in the general ſervice of piety and devotion; obſerving to him, that he was very able to compoſe excellent books of that kind, which would be apt to do more good as coming from a layman. This addreſs

Nelſon.

correſponded with the truly catholic ſpirit of our author; who accordingly publiſhed many works of piety, which are deſervedly eſteemed. Indeed it was this ſpirit, more than their agreement in ſtate principles, that firſt recommended them to one another. Mr Nelſon is obſerved to have encouraged Kettlewell to proceed in that ſoft and gentle manner, in which he excelled, in managing the Nonjurors controverſy; and animated him beſides to begin and proſecute ſome things for a public good, which otherwiſe would not have ſeen the light. Mr Kettlewell died in 1695, and left Mr Nelſon his ſole executor and truſtee; in conſequence of which, he publiſhed a poſthumous piece of piety, entitled, "An Office for Priſoners," &c. in 1697. He alſo publiſhed five other of his friend's poſthumous pieces, and furniſhed the chief materials for the account of his life afterwards.

At the ſame time he engaged zealouſly in every public ſcheme for the honour and intereſt, as well as for propagating the faith, and promoting the practice, of true Chriſtianity, both at home and abroad; ſeveral propoſals for building, repairing, and endowing churches, and charity ſchools particularly.

Upon the death of Dr William Lloyd, the deprived biſhop of Norwich, in the end of the year 1709, he returned to the communion of the church of England. Dr Lloyd was the laſt ſurviving of the deprived biſhops by the Revolution, except Dr Kenn, by whoſe advice Mr Nelſon was determined in this point. It had been a caſe in view ſome time, which had been bandied on both ſides, whether the continuance of their ſeparation from the church ſhould be ſchiſmatical or no, when that caſe became a fact; and our author had ſome conferences upon it with Dr Hickes, who was for perpetuating the Nonjuring church, and charging the ſchiſm upon the church eſtabliſhed. (See an account of this diſpute, with ſome letters that paſſed between them on the occaſion, in "The Conſtitution of the Catholic church, and the nature and conſequences of Schiſm ſet forth, in a collection of papers written by the late George Hickes, D. D. 1716," 8vo.) Mr Nelſon's tutor, Dr George Bull, biſhop of St David's, dying before the expiration of this year, he was eaſily prevailed upon by that prelate's ſon to draw up an account of his father's life and writings, as he had maintained a long and intimate friendſhip with his lordſhip, which gave him an opportunity of being acquainted with his ſolid and ſubſtantial worth. The life was publiſhed in 1713; and as our author had long before laboured under a conſtitutional weakneſs, which had brought on an aſthma and dropſy in the breaſt, the diſtemper grew to ſuch a height ſoon after the publication of that work, that, for the benefit of the air, he retired at length to Kenſington, where he expired on the 16th of January 1714-15, aged 59.

He was interred in the cemetery of St George's chapel, now a parochial church in Lamb's Conduit Fields, where a monument is erected to his memory, with a long and elegant Latin inſcription, written by Biſhop Smalridge. He was the firſt perſon buried in this cemetery; and as it was done to reconcile others to the place, who had taken an inſurmountable prejudice againſt it, ſo it proved a moſt prevailing precedent, and had the deſired effect. He publiſhed ſeveral works of piety, and left his whole eſtate to pious and charitable uſes, particularly to charity-ſchools. A good portrait of him was given by Mr Nichols, in 1779, to the Company of Stationers, and is placed in the parlour of their public hall. After the death of Sir Berkeley Lucy, Mr Nelſon's library was ſold by auction in 1760, together with that of Sir Berkeley, forming, united, a moſt extraordinary aſſemblage of devotion and infidelity. Several of Mr Nelſon's original letters, highly characteriſtic of his benevolence, may be ſeen in the Anecdotes of Bowyer. Mr Nichols has alſo in his poſſeſſion in MS. two excellent letters of advice from Mr Nelſon to his young couſins George and Gabriel Hanger, on their going to ſettle in Turkey; which have been obligingly offered for the uſe of any future biographer, but are too long for our limits.

NEMAUSUS, or Nemausum, (anc. geog.), the capital of the Arecomici in Gallia Narbonenſis; a colony, (Coin), with the ſurname *Auguſta*, (Inſcription). In it ſtands a Roman amphitheatre, which is ſtill almoſt entire. Now *Niſmes* in Languedoc.

NEMEA (Strabo, Livy); a river of Achaia, running between Sicyon and Corinth, the common boundary of both territories, and falling into the Corinthian bay.

Nemea (anc. geog.), ſituated between Cleonæ and Philus in Argolis; whether town, diſtrict, or other thing, uncertain; there a grove ſtood in which the Argives celebrated the Nemean games, and there happened all the fabulous circumſtances of the Nemean lion. The diſtrict Nemea is called *Bembinadia*, (Pliny); a village, *Bembina*, ſtanding near Nemea, (Strabo). Stephanus places Nemea in Elis; though not in Elis, but on its borders; Pliny, erroneouſly, in Arcadia. In the adjoining mountain is ſtill ſhown the den of the lion, diſtant 15 ſtadia from the place *Nemea*, (Pauſanias); in which ſtands a conſiderable temple of Jupiter Nemæus and Cleonæus, from the vicinity of theſe two places. This place gave name to the Nemæan games, celebrated every third year.

NEMEAN games, ſo called from Nemea, a village between the cities of Cleonæ and Philus, where they were celebrated every third year. The exerciſes were chariot-races, and all the parts of the Pentathlum. Theſe games were inſtituted in memory of Opheltes or Archemorus the ſon of Euphetes and Creuſa, and who was nurſed by Hypſipele; who leaving him in a meadow while ſhe went to ſhow the beſiegers of Thebes a fountain, at her return found him dead, and a ſerpent twined about his neck: whence the fountain, before called *Langia*, was named *Archemorus*; and the captains, to comfort Hypſipele, inſtituted theſe games.—Others aſcribe their inſtitution to Hercules, after his victory over the Nemean lion. Others allow, that they were inſtituted firſt in honour of Archemorus; but intermitted, and revived again by Hercules. The victors were crowned with parſley, an herb uſed at funerals, and feigned to have ſprung from Archemorus's blood. The Argives preſided at theſe games.

NEMESIANUS (Aurelius Olympius), a Latin poet who was born at Carthage, and flouriſhed about the year 281, under the emperor Carus, and his ſons Carinus and Numerian: the laſt of which emperors was ſo fond of poetry that he conteſted the glory with

Nemeſianus, who had written a poem upon fiſhing and maritime affairs. We have ſtill remaining a poem of our author called *Cynegeticon*, and four eclogues: they were publiſhed by Paulus Manutius in 1538; by Barthelet in 1613; at Leyden in 1653; with the notes of Janus Vlitias. Giraldi hath preſerved a fragment of Nemeſianus, which was communicated to him by Sannazarius, to whom we are obliged for our poet's works: for having found them written in Gothic characters, he procured them to be put into the Roman, and then ſent them to Paulus Manutius. Although this poem hath acquired ſome reputation, it is greatly inferior to thoſe of Oppian and Gratian upon the ſame ſubject; yet Nemeſianus's ſtyle is natural enough, and has ſome degree of elegance. The world was ſo much poſſeſſed with an opinion of his poem in the eighth century, that it was read among the claſſics in the public ſchools, particularly in the time of Charlemagne, as appears from a letter of the celebrated Hincmar biſhop of Rheims to his nephew Hincmar of Laon.

NEMESIS, in Pagan worſhip, the daughter of Jupiter and Neceſſity, or, according to others, of Oceanus and Nox, had the care of revenging the crimes which human juſtice left unpuniſhed. She was alſo called *Adraſtæa*, becauſe Adraſtus king of Argos firſt raiſed an altar to her; and *Rhamnuſia*, from her having a magnificent temple at Rhamnus in Attica. She had likewiſe a temple at Rome in the Capitol. She is repreſented with a ſtern countenance, holding a whip in one hand and a pair of ſcales in the other.

NEMESIUS, a Greek philoſopher who embraced Chriſtianity, and was made biſhop of Emeſa in Phœnicia, where he had his birth; he flouriſhed in the beginning of the fifth century. We have a piece by him entitled *De Natura Hominis*, in which he refutes the fatality of the Stoics and the errors of the Manichees, the Apollianariſts, and the Eunomians; but he eſpouſes the opinion of Origen concerning the pre-exiſtence of ſouls (A). This treatiſe was tranſlated by Valla, and printed in 1535. Another verſion was afterwards made of it by Ellebodius, and printed in 1665; it is alſo inſerted in the *Bibliotheca Patrum*, in Greek and Latin. Laſtly, Another edition was publiſhed at Oxford in 1671, folio, with a learned preface, wherein the editor endeavours to prove, from a paſſage in this book, that the circulation of the blood was known to Nemeſius; which, however, was ſince ſhown to be a miſtake by Dr Freind, in his *Hiſtory of Phyſic*.

NEMINE CONTRADICENTE, "none contradicting it;" a term chiefly uſed in parliament when any thing is carried without oppoſition.

NEMOURS, a town of the Iſle of France in the Gatinois, with the title of a duchy. It is ſeated on the river Loing, in E. Long. 2. 45. N. Lat. 48. 15.

NENAGH, a poſt and fair town of Ireland, in the county of Tipperary, and province of Munſter, 75 miles from Dublin. It is ſituated on a branch of the river Shannon which runs into Lough-Derg. Here ſtands the ruins of an old caſtle called Nenagh-round. Alſo thoſe of an hoſpital founded in the year 1200, for canons following the rule of St Auguſtin. It was dedicated to St John the Baptiſt, and was uſually called *Tearhon*, or St John's houſe. In the reign of Henry III. a friary for conventual Franciſcans was alſo founded here, and eſteemed the richeſt foundation of that order in the kingdom. Here is a barrack for two troops of horſe. This town was burnt on St Stephen's day 1348, by the Iriſh. The fairs held here are four.

NENIA, or NÆNIA, in the ancient poetry, a kind of funeral ſong ſung to the muſic of flutes at the obſequies of the dead. Authors repreſent them as ſorry compoſitions, ſung by hired women mourners called *Præficæ*. The firſt riſe of theſe Nenia is aſcribed to the phyſicians. In the heathen antiquity, the goddeſs of tears and funerals was called *Nenia*; whom ſome ſuppoſe to have given that name to the funeral ſong, and others to have taken her name from it.

NEOCESARIA, (Pliny), a town of Pontus on the ſouth or the left ſide of the Lycus. About the year 342, when Leontius and Salluſtius were conſuls, it was entirely ruined by a dreadful earthquake, no edifice having withſtood the violence of the ſhock, except the church and the biſhop's habitation, who was ſaved, with the clergy and ſome other pious perſons, while the reſt of the inhabitants were buried in its ruins.

NEOMAGUS, (Ptolemy); NOVIOMAGUS, (Antonine); a town of the Regni in Britain: now thought to be Guildford in Surry, (Lhuyd); or Croydon, (Talbot.) But Camden takes it to be Woodcote, two miles to the ſouth of Croydon, where traces of an ancient town are ſtill to be ſeen.

NEOMAGUS, (Ptolemy); *Noviomagus*, (Antonine); a town of the Treviri on the Moſelle. Now *Numagen* 14 miles eaſt, below Triers.

NEOMAGUS, (Ptolemy); *Noviomagus Lexoviorum*, (Antonine); a town of Gallia Celtica. Now *Liſeux*, in Normandy.

NEOMAGUS, (Ptolemy), *Noviomagus Nemetum*, (Antonine.) Now *Spire*, a city of the Palatinate, on the left or weſt ſide of the Rhine.

NEOMAGUS, (Ptolemy); a town of Gallia Narbonenſis, on the confines of the Tricaſtini. Now *Nyons* in Dauphiné.

NEOMENIA, or NOUMENIA, a feſtival of the ancient Greeks, at the beginning of every lunar month, which, as the name imports, was obſerved upon the day of the new moon, in honour of all the gods, but eſpecially Apollo, who was called *Neomenios*, becauſe the ſun is the fountain of light; and whatever diſtinction of times and ſeaſons may be taken from other planets, yet they are all owing to him as the original of thoſe borrowed rays by which they ſhine.

The games and public entertainments at theſe feſtivals were made by the rich, to whoſe tables the poor flocked in great numbers. The Athenians at theſe

---

(A) It is much more probable that he and Origen both brought their opinion with them from the ſchools of philoſophy, than that either of them borrowed it from the other. See METAPHYSICS, Part III. Chap. IV.

theſe times offered ſolemn prayers and ſacrifices for the proſperity of their country during the enſuing month. See Games.

The Jews had alſo their neomenia, or feaſt of the new moon, on which peculiar ſacrifices were appointed: and on this day they had a ſort of family entertainment and rejoicing. The moſt celebrated neomenia of all others was that at the beginning of the civil year, or firſt day of the month Tiſri, on which no ſervile labour was performed: they then offered particular burnt ſacrifices, and ſounded the trumpets of the temple. The modern Jews keep the neomenia only as a feaſt of devotion, which any one may obſerve or not as he pleaſes.

NEOPHYTES, "new plants;" a name given by the ancient Chriſtians to thoſe heathens who had newly embraced the faith; ſuch perſons being conſidered as regenerated, or born anew by baptiſm. The term *neophytes* has been alſo uſed for new prieſts, or thoſe juſt admitted into orders, and ſometimes for the novices in monaſteries. It is ſtill applied to the converts made by the miſſionaries among the infidels.

NEPA, in zoology, a genus of inſects belonging to the order of hemiptera. The roſtrum is inflected; the antennæ are ſhorter than the thorax; and the hind feet are hairy, and fitted for ſwimming. There are ſeven ſpecies. The four wings are folded together croſſwiſe, with the anterior part coriaceous. The two fore feet are cheliform, or reſemble the claws of a crab; the other four are formed for walking. We have but three ſpecies of this genus, all three of which are found in the water, where they dwell, as do their larvæ and chryſalids. It is likewiſe in the water that we find the eggs of the water ſcorpion. Thoſe eggs, of an oblong ſhape, have at one of their extremities two or more briſtles or hairs. The inſect ſinks its egg into the ſtalk of a bullruſh or ſome other water plant, ſo that the egg lies concealed, and only the hairs or briſtles ſtick out, and are to be ſeen. One may eaſily preſerve in water thoſe ſtalks loaded with eggs, and ſee the young water ſcorpions hatched under one's own roof, or at leaſt their larvæ. Theſe inſects are voracious, and feed on other aquatic animals, which they pierce and tear with their ſharp roſtrum, while they hold them with the forceps of their fore feet.—They fly well, eſpecially in the evening and night, and they convey themſelves from one pool to another, eſpecially when that they are in begins to dry up. Mr Geoffroy aſſerts, that the pedes cheliformes, or fore feet of the nepa, are the antennæ of the inſect, which, according to him, has but four feet.

NEPENTHES, in botany: A genus of the tetrandria order, belonging to the gynandria claſs of plants; and in the natural method ranking among thoſe of which the order is doubtful. The calyx is quadripartite; there is no corolla; the capſule is quadrilocular.

NEPETA, Catmint, or *Nep*, in botany: A genus of the gymnoſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 42d order, *Verticillatæ*. The under lip of the corolla has a ſmall middle ſegment crenated; the margin of the throat is reflexed; the ſtamina approach one another. There are 14 ſpecies; the moſt remarkable is the cataria, common nep, or catmint. This is a native of many parts of Britain, growing about hedges and in waſte places. The ſtalk is a yard high, and branched; the leaves are hoary; the flowers fleſh coloured, growing verticillate in ſpikes at the tops of the branches: the middle ſegment of the lower lip is ſpotted with red. The plant has a bitter taſte, and ſtrong ſmell, not unlike pennyroyal. An infuſion of this plant is reckoned a good cephalic and emmenagogue; being found very efficacious in chlorotic caſes. Two ounces of the expreſſed juice may be given for a doſe. It is called *catmint*, becauſe cats are very fond of it, eſpecially when it is withered; for then they will roll themſelves on it, and tear it to pieces, chewing it in their mouths with great pleaſure. Mr Ray mentions his having tranſplanted ſome of the plants of this ſort from the fields into his garden, which were ſoon deſtroyed by the cats; but the plants which came up from ſeeds in his garden eſcaped: this verifies an old proverb, *viz.* "If you ſet it, the cats will eat it; if you ſow it, the cats will not know it." Mr Withering is of opinion, that where there is a quantity of plants growing together, the cats will not meddle with them; but Mr Millar aſſures us, that he has frequently tranſplanted one of theſe plants from another part of the garden, within two feet of which ſome came up from ſeeds; in which caſe the latter have remained unhurt, when the former have been torn to pieces and deſtroyed: he acknowledges, however, that, where there is a large quantity of the herb growing together, they will not meddle with it. This plant is very hardy, and is eaſily propagated by ſeeds. If ſown upon a poor dry ſoil, the plants will not grow too rank, but will continue longer, and appear much handſomer, than in rich ground, where they grow too luxuriant, and have not ſo ſtrong a ſcent.

NEPHELIUM, in botany: A genus of the pentandria order, belonging to the monœcia claſs of plants. The male calyx is quinquidentate; there is no corolla: the female calyx is quadrifid; there is no corolla.—There are two germens and two ſtyles on each: the fruit are two dry plumbs, muricated, and monoſpermous.

NEPHEW, a term relative to uncle and aunt, ſignifying a brother's or ſiſter's ſon; who, according to the civil law, is in the third degree of conſanguinity, but according to the canon in the ſecond.

NEPHRITIC, ſomething that relates to the kidneys. See Kidney.

Nephritic Wood, (lignum nephriticum), a wood of a very denſe and compact texture, and of a fine grain, brought to us from New Spain in ſmall blocks, in its natural ſtate, and covered with its bark. It is to be choſen of a pale colour, ſound and firm, and ſuch as has not loſt its acrid taſte: for the ſureſt teſt of it is the infuſing it in water; for a piece of it infuſed only half an hour in cold water, gives it a changeable colour, which is blue or yellow as variouſly held to the light. If the vial it is in be held between the eye and the light, the tincture appears yellow; but if the eye be placed between the light and the vial, it appears blue. We often meet with this wood adulterated with others of the ſame pale colour; but the duſkiſh black hue of the bark is a ſtriking character of this.

The tree is the *coatli* of Hernandez. It grows to the height of our pear tree, and its wood while freſh is much of the ſame texture and colour; the leaves are ſmall and oblong, not exceeding half an inch in length, or a third of an inch in breadth: the flowers are ſmall, of a pale yellow colour, and oblong ſhape, ſtanding in ſpikes: the cups they ſtand in are divided into five ſegments at the edge, and are covered with a reddiſh down. This is the beſt deſcription of the tree that can be collected from what has been hitherto written of it; nobody having yet had an opportunity of taking its true characters.

This wood is ſaid to be a very good diuretic; and we are told it is uſed among the Indians is all diſeaſes of the kidneys and bladder, and in ſuppreſſion of urine, from whatever cauſe. It is alſo recommended in fevers, and in obſtructions of the viſcera. The way of taking it among the Indians is only an infuſion in cold water. Theſe uſes are not however properly aſcertained. See Guilandina.

Nephritic Stone. See *Jade Stone.*

NEPHRITICS, in pharmacy, medicines proper for diſeaſes of the kidneys, eſpecially the ſtone.—Such particularly are the roots of althæa, dog's graſs, aſparagus, ſago, pellitory of the wall, mallows, pimpinella, red chick peaſe, peach kernels, turpentine, &c.

NEPHRITIS, or inflammation of the kidneys. See Medicine, N° 200.

NEPOS (Cornelius), a celebrated Latin biographer, who flouriſhed in the time of Julius Cæſar, and lived, according to St Jerome, to the ſixth year of Auguſtus. He was an Italian, if we may credit Catullus, and born at Hoſtilia, a ſmall town in the territory of Verona, in Ciſalpine Gaul. Auſonius, however, will have it that he was born in the Gauls: and in that they may both be in the right, provided that under the name of *Gaul* is comprehended *Gallia Ciſalpina*, which is in Italy. Leander Alberti thinks Nepos's country was Verona; and he is ſure that he was either born in that city or neighbourhood. For the reſt, Cicero and Atticus were friends of our author; who wrote the lives of the Greek hiſtorians, as he himſelf atteſts in that of Dion, ſpeaking of Philiſtus. What he ſays, alſo, in the lives of Cato and Hannibal, proves that he had alſo written the lives of the Latin captains and hiſtorians. He wrote ſome other excellent works which are loſt.

All that we have left of his at preſent is, "The Lives of the illuſtrious Greek and Roman Captains;" which were a long time aſcribed to Æmilius Probus, who publiſhed them, as it is ſaid, under his own name, to inſinuate himſelf thereby into the favour of the emperor Theodoſius; but, in the courſe of time, the fraud has been diſcovered, although ſeveral learned perſons have confounded the two authors. This piece has been tranſlated into French by the Sieur de Claveret, with a dedication to the duke of Longueville, in 1663; and again by M. le Gras, then of the congregation of the Oratory at Paris 1729, 12mo. We have an excellent tranſlation of it into Engliſh, by ſeveral hands at Oxford, which has gone through ſeveral editions.

NEPTUNE, in Pagan worſhip, the god of the ſea, was the ſon of Saturn and Veſta or Ops, and the brother of Jupiter and Pluto. He aſſiſted Jupiter in his expeditions; on which that god, when he arrived at the ſupreme power, aſſigned him the ſea and the iſlands for his empire. He was, however, expelled from heaven with Apollo for conſpiring againſt Jupiter, when they were both employed by Laomedon king of Phrygia in building the walls of Troy; but that prince diſmiſſing Neptune without a reward, he ſent a ſea monſter to lay waſte the country, on which he was obliged to expoſe his daughter Heſione. He is ſaid to have been the firſt inventor of horſemanſhip and chariot racing; on which account Mithridates king of Pontus threw chariots drawn by four horſes into the ſea in honour of this god; and the Romans inſtituted horſe races in the circus at his feſtival, during which all other horſes left working, and the mules were adorned with wreaths of flowers.

In a conteſt with Minerva he produced a horſe by ſtriking the earth with his trident; and on another occaſion, in a trial of ſkill with Minerva and Vulcan, produced a bull, whence that animal was ſacrificed to him. His favourite wife was Amphytrite, whom he long courted in vain, till ſending a dolphin to intercede for him, he met with ſucceſs; on which he rewarded the dolphin by placing him among the ſtars. He had alſo two other wives, one of whom was called *Salaſia* from the ſalt water; the other *Venilia* from the ebbing and flowing of the tides. He had likewiſe many concubines, by whom he had a great number of children. He is repreſented with black hair, with a garment of an azure or ſea green, holding his trident in his hand, and ſeated in a large ſhell drawn by ſea horſes, attended by the ſea gods Palemon, Glaucus, and Phorcys, and the ſea goddeſſes Thetis, Melita, and Panopæa, and a long train of tritons and ſea nymphs.

This deity was in Egypt known by the name of *Canobus* or *Canopus*, and was worſhipped as the *numen aquarum* or ſpirit of the Nile. His emblem was the figure of certain vaſes or pitchers, with which the Egyptians filtrated the water of their ſacred river, in order to purify and render it fit for uſe. From the mouth of each of theſe vaſes, which were charged with hieroglyphics, aroſe the head, and ſometimes the head and hands, of a man or woman. Such are the emblems which ſtill remain of the Egyptian Neptune or Canobus; and it was by this emblem that the tutelar god of Egypt vanquiſhed the god of Chaldea in the ridiculous manner mentioned by Ruffinus in his eccleſiaſtical hiſtory †.

"The Chaldæans (ſays he) who adored the fire, carried their god into various countries that he might try his ſtrength in conteſts with other gods. He vanquiſhed, as we may eaſily conceive, the images made of gold, ſilver, braſs, and wood, &c. by reducing them to aſhes; and thus the worſhip of fire was everywhere eſtabliſhed. The prieſt of Canobus, unwilling, as became him, to admit the ſuperiority of ſtrange gods, contrived to make his god vanquiſh the [illegible] of Chaldæa in a pitched battle. The vaſes which were worſhipped as the emblems of Canobus being uſed for filtering the waters of the Nile, were of courſe perforated on all ſides with very ſmall holes. This faithful prieſt having ſtopped all the holes in one of theſe with wax, and painted the vaſe of different colours for a reaſon which the reader will admit to be a good one, filled it up with water, and fitted to its mouth the head of an idol. This emblem of Canobus was then placed in a ſmall fire brought by the Chaldeans,

† cap

Chaldæans as the emblem of their god; and thus the gods of Egypt and Chaldæa were forced into battle. The conteſt, however, was of ſhort duration. The heat melting the wax made way for the water to run out, which quickly extinguiſhed the fire; and thus Canôbus vanquiſhed the god of the Chaldæans." Ridiculous as this ſtory is, it is perfectly ſuitable to the genius of Paganiſm, and the mean artifices of the Pagan prieſthood; but we ſuſpect that the hiſtorian laboured under one miſtake, and ſubſtituted the Chaldæans inſtead of the Perſians. See POLYTHEISM.

NEREIDS, in the Pagan theology, ſea nymphs, daughters of Nereus and Doris.—The Nereids were eſteemed very handſome; inſomuch that Caſſiope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the Nereids, they were ſo enraged that they ſent a prodigious ſea monſter into the country; and, to appeaſe them, ſhe was commanded by the oracle to expoſe her daughter Andromeda, bound to a rock, to be devoured by the monſter. In ancient monuments, the Nereids are repreſented riding upon ſea horſes; ſometimes with an entire human form, and at other times with the tail of a fiſh.

NEREIS, in zoology, a genus of animals belonging to the order of vermes mollusca. The body is oblong, linear, and fitted for creeping; it is furniſhed with lateral pencilled tentacula. There are 11 ſpecies; of which the moſt remarkable are the five following:

Plat CCCXLV. fig. 1. 1. The *noctiluca*, or noctilucous nereis, which inhabits almoſt every ſea, and is one of the cauſes of the luminouſneſs of the water. Theſe creatures ſhine like glow-worms, but with a brighter ſplendour, ſo as at night to make the element appear as if on fire all around. Their bodies are ſo minute as to elude examination by the naked eye.

It is ſometimes called *nereis phoſphorans;* and is thus deſcribed by Griſelin: The head is roundiſh and flat, and the mouth acuminated. The two horns or feelers are ſhort and ſubulated. The eyes are prominent, and placed on each ſide the head. The body is compoſed of about 23 ſegments or joints, which are much leſs near the tail than at the head. Theſe ſegments on both ſides the animal all end in a ſhort conical apex, out of which proceeds a little bundle of hairs: from under theſe bundles the feet grow in the form of ſmall flexile ſubulated figments deſtitute of any thing like claws. It is ſcarcely two lines long, and is quite pellucid, and its colour is that of water green. They are found upon all kinds of marine plants; but they often leave them, and are found upon the ſurface of the water; they are frequent at all ſeaſons, but eſpecially in ſummer before ſtormy weather, when they are more agitated and more luminous. Their numbers, and wonderful agility, added to their pellucid and ſhining quality, do not a little contribute to their illuminating the ſea, for myriads of thoſe animalculæ may be contained in the portion of a ſmall cup of ſea water. Innumerable quantities of them lodge in the cavities of the ſcales of fiſhes, and to them probably do the fiſhes owe their noctilucous quality. "I have obſerved with great attention (ſays Barbut), a fiſh juſt caught out of the ſea, whoſe body was almoſt covered with them; and have examined them in the dark: they twiſt and curl themſelves with amazing agility, but ſoon retire out of our contracted ſight; probably their glittering numbers dazzling the eye, and their extreme minuteneſs eluding our reſearches. It is to be obſerved, that when the unctuous moiſture which covers the ſcales of fiſhes is exhauſted by the air, theſe animals are not to be ſeen; nor are the fiſhes then noctilucous, that matter being perhaps their nouriſhment when living, as they themſelves afford food to many marine animals. They do not ſhine in the day time, becauſe the ſolar rays are too powerful for their light, however aggregate or immenſe their number." Their appearance is particularly brilliant when the wind is in the eaſt and ſouth-eaſt points, and in winter nights preceded by a warm day. If water containing theſe animalcules be kept warm, they retain their light two whole days after they are dead; but in cold water loſe it in eight hours: motion and warmth, which increaſe their vivacity and ſtrength, increaſe their light alſo.

2. *Nereis lacuſtris*, or bog nereis. Fig. 2. The body of the ſize of a hog's ſhort briſtle, tranſparent, as it were articulated, and on either ſide at every articulation provided with a ſhort ſetaceous foot; interiorly it ſeems to conſiſt in a manner of oval-ſhaped articulations, and a back formed by two lines bent backwards. It inhabits marſhes abounding in clay, where it remains under ground, puſhing out its other extremity by reaſon of its continual motion. When taken out it twiſts itſelf up. Is frequent in Sweden.

3. *Nereis cirroſa*, or waving nereis. Fig. 3. The body is red, lumbriciform, with 65 notches, furniſhed on both ſides with two rows of briſtles. At each ſide of the head ten filaments, at the ſides of the mouth many, twice as long as the former. It dwells in Norway, on rocks at the bottom of the ſea. It vomits a red liquor with which it tinges the water.

4. *Nereis cærulea*, or blue nereis. Fig. 4. It inhabits the ocean; where it deſtroys the ſerpulæ and teredines.

5. *Nereis gigantæa*, or giant nereis. Fig. 5. This is a peculiar ſpecies of thoſe large worms that make their way into decayed piles driven down into the ſea, which they bore through and feed upon, whence they are called *ſea worms* or nereis. From head to tail they are beſet on either ſide with ſmall tufts terminating in three points; which are like the fine hair pencils uſed by painters, and compoſed of ſhining briſtles of various colours. The upper part of the body in this worm is all over covered with ſmall hairs. The rings of which it is formed are cloſely preſſed together, and yield to the touch. The three rows of ſmall tufts we have been deſcribing, ſerve this nereis inſtead of feet, which it uſes to go forwards as fiſhes do their fins.

NEREUS, (fab. hiſt.), a marine deity, was the ſon of Oceanus and Thetis. He ſettled in the Ægean ſea, was conſidered as a prophet, and had the power of aſſuming what form he pleaſed. He married his ſiſter Doris, by whom he had 50 daughters called the *Nereids*, who conſtantly attended on Neptune, and when he went abroad ſurrounded his chariot.

NERI (S. Philippe de), founder of the congregation of the Oratory in Italy, was born of a noble family at Florence, on the 25th of July 1515. Educated in the principles of piety and learning, he ſoon became

Neri

Nero.

became diſtinguiſhed for his knowledge and virtue. At the age of 19 he went to Rome, where he improved his mind, aſſiſted the ſick, and gave many proofs of ſelf-denial and humility. Philippe, being raiſed to the prieſthood at the age of 36, inſtituted, in 1550, a celebrated fellowſhip in the church of St Saviour del Campo, for the relief of poor foreigners, of pilgrims, and of convaleſcents, who had no place whither they could retire. This ſociety was the cradle, if we may ſay ſo, of the congregation of the Oratory. The holy founder having gained over to God Salviati brother to the cardinal of the ſame name, Tarugio afterwards cardinal, the celebrated Baronius, and ſeveral others, they began to form themſelves into a ſociety in 1564. The ſpiritual exerciſes had been transferred in 1558 to the church of Saint Jerome de la Charité, which Philippe did not leave till 1574, when he went to ſtay at Saint John of the Florentines. Pope Gregory XIII. gave his approbation of the congregation in the following year. The father of this new warfare ſent out ſome of his children, by whom his order was ſpread thoughout Italy. Nor is there any reaſon to be ſurpriſed at its rapid ſucceſs. No vow is taken in this congregation; charity is the only bond of connexion. The general continues only three years in office, and his orders are not thoſe of a tyrant or a deſpot. The founder died at Rome on the night between the 25th and 26th of May 1595, aged 80. He had reſigned the generalſhip three years before in favour of Baronius, who, by his advice, was engaged in the eccleſiaſtical annals. The conſtitutions which he left for his congregation were not printed till 1612. The principal employment which he allots to the prieſts of his order, is to give, every day, in their oratory or church, inſtructions ſuited to the underſtandings of their hearers: an office truly apoſtolical, and which the followers of Neri diſcharge with ſucceſs. They humble themſelves, that they may exalt to God the ſoul of the ſimple. Philippe was canonized in 1622 by Gregory XV.

There was a learned man of the name of Neri (Anthony), from whom we have a curious book printed at Florence 1612, in 4to, with this title *Dell' Arte verraria Libri VII.*; and a Dominican named *Thomas Neri*, who employed his pen in defence of his fellow monk, the famous Savonarole.

NERIUM, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 30th order, *Contortæ*. There are two erect follicles; the ſeeds plumy; the tube of the corolla terminated by a lacerated crown. There are five ſpecies, all of them natives of the warmer climates: the moſt remarkable of which are, 1. The oleander, South ſea roſe: this is a beautiful ſhrub, cultivated in gardens on account of its flowers, which are of a fine purple, and in cluſters, but of an indifferent ſmell: the whole plant is poiſonous, and eſpecially the bark of the roots. 2. The antidyſintericum, a native of Ceylon: the bark of which is an article of materia medica, under the name of *Coneſſi*. 3. The tinctorium, a new ſpecies with beautiful blue flowers lately diſcovered by Dr Roxburgh at Madras. A decoction of the leaves, with an addition of lime water, makes an indigo of fine quality.

Nero.

NERO (Claudius Domitius Cæſar), a celebrated Roman emperor, ſon of Caius Domitius Ahenobarbus and Agrippina the daughter of Germanicus. He was adopted by the emperor Claudius, A. D. 50, and four years after he ſucceeded to him on the throne. In the beginning of his reign he ſhowed ſeveral marks of the greateſt kindneſs and condeſcenſion, affability, complaiſance, and popularity. The object of his adminiſtration ſeemed to be the good of his people; and when he was deſired to ſign his name to a liſt of malefactors that were to be executed, he exclaimed, *Would to heaven I could not write!* He hated flattery; and when the ſenate had liberally commended the wiſdom of his government, he deſired them to keep their praiſes till he deſerved them. Theſe promiſing virtues ſoon, however, proved to be artificial: Nero ſoon diſplayed the real propenſities of his nature. He delivered himſelf from the ſway of his mother, and at laſt ordered her to be murdered. This unnatural act of barbarity might aſtoniſh ſome, but Nero had his devoted adherents; and when he declared that he had taken away his mother's life to ſave himſelf from ruin, the ſenate applauded his meaſures, and the people ſignified their approbation. Many of his courtiers ſhared her unhappy fate; and Nero ſacrificed to his fury or caprice all ſuch as obſtructed his pleaſure or diverted his inclination. In the night he generally went from his palace to viſit the meaneſt taverns, and all the ſcenes of debauchery which Rome contained. In this nocturnal riot he was fond of inſulting the people in the ſtreets; and his attempts to offer violence to the wife of a Roman ſenator nearly coſt him his life. He alſo turned actor, and openly appeared on the Roman ſtage in the meaneſt characters. In his attempts to excel in muſic, and to conquer the diſadvantages of a hoarſe diſagreeable voice, he moderated his meals, and often paſſed the day without eating. The Olympian games attracted his notice: he went into Greece, and preſented himſelf a candidate for the public honour. He was defeated in wreſtling; but the flattery of the ſpectators adjudged him the victory, and he returned to Rome with all the pomp and ſplendour of an eaſtern conqueror, drawn in the chariot of Auguſtus, and attended by a band of muſicians, actors, and ſtage-dancers from every part of the empire. Theſe private and public amuſements of the emperor were indeed innocent; his character only was injured, and not the lives of the people. His conduct, however, ſoon became more abominable: he diſguiſed himſelf in the habit of a woman, and was publicly married to one of his eunuchs. This violence to nature and decency was ſoon exchanged for another: Nero reſumed his ſex, and celebrated his nuptials with one of his meaneſt catamites: and it was on this occaſion that one of the Romans obſerved that the world would have been happy if Nero's father had had ſuch a wife. But his cruelty was now diſplayed in a ſtill higher degree, for he ſacrificed to his wantonneſs his wife Octavia Poppæa, and the celebrated writers, Seneca, Lucan, Petronius, &c. Nor did the Chriſtians eſcape his barbarity. He had heard of the burning of Troy; and as he wiſhed to renew that diſmal ſcene, he cauſed Rome to be ſet on fire in different places. The conflagration became ſoon univerſal, and during nine ſucceſſive days the fire continued. All was deſolation: nothing was heard but the lamentations of mothers whoſe children had periſhed in the flames, the groans of the dying, and the continual fall of palaces and buildings. Nero was the only one who enjoyed the general conſternation. He placed himſelf on the top of a high tower, and he ſung on his lyre the deſtruction of Troy, a dreadful ſcene which his barbarity had realized before his eyes. He attempted to avert the public odium from his head by a pretended commiſeration of the miſeries of his ſubjects. He began to repair the ſtreets and the public buildings at his own expence. He built himſelf a celebrated palace, which he called his golden houſe. It was liberally adorned with gold, with precious ſtones, and with every thing rare and exquiſite. It contained ſpacious fields, artificial lakes, woods, gardens, orchards, and whatever exhibited a beautiful ſcene. The entrance of this edifice could admit a large coloſſus of the emperor 120 feet high; the galleries were each a mile long, and the whole was covered with gold. The roofs of the dining halls repreſented the firmament, in motion as well as in figure; and continually turned round night and day, ſhowering down all ſorts of perfumes and ſweet waters. When this grand edifice, which, according to Pliny, extended all round the city, was finiſhed, Nero ſaid, that now he could lodge like a man. His profuſion was not leſs remarkable in all his other actions. When he went a fiſhing, his nets were of gold and ſilk. He never appeared twice in the ſame garment; and when he took a voyage, there were thouſands of ſervants to take care of his wardrobe. This continuation of debauchery and extravagance at laſt rouſed the people. Many conſpiracies were formed againſt him; but they were generally diſcovered, and ſuch as were acceſſory ſuffered the ſevereſt puniſhments. The moſt dangerous conſpiracy againſt Nero's life was that of Piſo, from which he was ſaved by the confeſſion of a ſlave. The conſpiracy of Galba proved more ſucceſsful, who, when he was informed that his plot was known to Nero, declared himſelf emperor. The unpopularity of Nero favoured his cauſe; he was acknowledged by all the Roman empire, and the ſenate condemned the tyrant to be dragged naked through the ſtreets of Rome, and whipped to death, and afterwards to be thrown down from the Tarpeian rock like the meaneſt malefactor. This, however, was not executed; for Nero prevented it by a voluntary death. He killed himſelf, A. D. 68, in the 32d year of his age, after a reign of 13 years and eight months. Rome was filled with acclamations at it; and the citizens, more ſtrongly to indicate their joy, wore caps, ſuch as were generally uſed by ſlaves who had received their freedom. Their vengeance was not only exerciſed againſt the ſtatues of the deceaſed monſter, but many of his friends were the object of the public reſentment; and many were cruſhed to pieces in ſuch a violent manner, that one of the ſenators, amid the univerſal joy, ſaid that he was afraid they ſhould ſoon have cauſe to wiſh for Nero. The tyrant, as he expired, requeſted that his head might not be cut off from his body, and expoſed to the inſolence of the populace, but that the whole might be burned on the funeral pile. His requeſt was granted by one of Galba's freedmen, and his obſequies were performed with the uſual ceremonies. Though his death ſeemed to be the ſource of general gladneſs, yet many of his favourites lamented his fall, and were grieved to ſee that their pleaſures and amuſements were ſtopped by the death of this patron of debauchery and extravagance. Even the king of Parthia ſent ambaſſadors to Rome, to condole with the Romans, and to beg that they would honour and revere the memory of Nero. His ſtatues were alſo crowned with garlands of flowers; and many imagined that he was not dead, but that he would ſoon make his appearance and take vengeance on his enemies. It will be ſufficient to obſerve, in finiſhing the character of this tyrannical monſter, that the name of *Nero* is even now uſed emphatically to expreſs a barbarous and unfeeling oppreſſor. Pliny calls him the common enemy and fury of mankind; and ſo indeed he has been called by all writers, who exhibit Nero as a pattern of the moſt execrable barbarity and unpardonable wantonneſs. The ſame Pliny furniſhes us with this ſingular anecdote of him: "Nero had ordered himſelf to be painted under the figure of a coloſſus, upon cloth or canvas, 120 feet in height." He adds, "that this prepoſterous picture, when it was finiſhed, met with its fate from lightning, which conſumed it, and involved likewiſe the moſt beautiful part of the gardens where it was placed in the conflagration."

NERVA (Cocceius), a Roman emperor after Domitian, who was the laſt of the 12 Cæſars. He was a native of Narnia in Umbria; his family however was originally of Crete. Dion Caſſius ſays he was born on the 17th of March, in the 18th year of Tiberius's reign, and of the Chriſtian era the 32d. Nero in the 12th year of his reign made him prætor, and erected a ſtatue for him in the palace on account of his poems (for he was one of the beſt poets of his age), ſome of which were inſcribed to him. He was conſul in 71 with Veſpaſian, and in 90 with Domitian.

Ancient authors uniformly celebrate him as a prince of a moſt mild and humane temper, of great moderation and generoſity, who looked on his office as emperor, not as if it was for his own advantage, but for that of his people; and whilſt he reigned, which was however but for a ſhort time, he made the happineſs of his ſubjects his only end and purſuit. He narrowly eſcaped death under Domitian; was naturally of a weak and timorous diſpoſition; and, as ſome ſay, addicted to exceſſive drinking. The Romans unanimouſly choſe him emperor; and they had no cauſe to repent of their choice, for he was conſtantly attentive to what could make them happy; he was generous, merciful, and diſintereſted. An inſtance of his great lenity appears in his pardoning Calpurnius Craſſus who conſpired againſt him. In ſhort, he omitted nothing that might contribute to the reſtoring of the empire to its former luſtre: recalling thoſe who had been baniſhed for religion, and redreſſing all grievances that came to his knowledge. He however found his ſtrength failing, and that it would be impoſſible for him to finiſh his deſigns, in conſequence of which he adopted Trajan. After his death, which happened in the year 98, he was ranked among the gods. He was the firſt Roman emperor of foreign extraction.

NERVES, in anatomy, certain white gliſtening cords, proceeding from the brain and ſpinal marrow, and dividing into very ſmall branches, which are ſent off throughout all parts of the body; and which are

found to be the organs of ſenſation and motion. See Anatomy, N° 136.

NERVOUS fluid. See Anatomy, N° 136.

NESSUS (fab. hiſt.), a celebrated Centaur, ſon of Ixion and a Cloud. He offered violence to Dejanira whom Hercules had entruſted to his care, with orders to carry her acroſs the river Evenus. Hercules ſaw the diſtreſs of his wife from the oppoſite ſhore of the river, and immediately he let fly one of his poiſoned arrows, which ſtruck the Centaur to the heart. Neſſus, as he expired, gave the tunic he then wore to Dejanira, aſſuring her that from the poiſoned blood which had flowed from his wounds, it had received the power of calling a huſband away from unlawful loves. Dejanira received it with pleaſure, and this mournful preſent cauſed the death of Hercules.——A river which ſeparates Thrace from Macedonia. It is alſo called *Neſus*, *Neſtos*, and *Neſtus*.

NEST. See Nidus.

Eatable Birds Nests. See *Birds Neſts*.

NESTOR (fab. hiſt.), a ſon of Neleus and Chloris, nephew to Pelias and grandſon to Neptune. He had eleven brothers, who were all killed with his father by Hercules. His tender age detained him at home, and was the cauſe of his preſervation. The conqueror ſpared his life and placed him upon the throne of Pylos. He married Eurydice the daughter of Clymenus; or, according to others, Anaxibia the daughter of Atreus. He ſoon diſtinguiſhed himſelf in the field of battle; and was preſent at the nuptials of Perithous, when a bloody engagement took place between the Lapithæ and Centaurs. As king of Pylos and Meſſenia he led his ſubjects to the Trojan war, where he diſtinguiſhed himſelf among the reſt of the Grecian chiefs, by eloquence, addreſs, wiſdom, juſtice, and uncommon prudence. Homer diſplays his character as the moſt perfect of all his heroes; and Agamemnon exclaims, that if he had 20 generals like Neſtor, he ſhould ſoon ſee the walls of Troy reduced to aſhes. After the Trojan war Neſtor retired to Greece, where he enjoyed in the boſom of his family the peace and tranquillity which were due to his wiſdom and to his age. The manner and the time of his death are unknown: the ancients are all agreed that he lived three generations of men; which length of time is ſuppoſed to be 300 years, though more probably only 90 years, allowing 30 years for each generation. From that circumſtance, therefore, it was uſual among the Greeks and the Latins, when they wiſhed a long and happy life to their friends, to wiſh them to ſee the years of Neſtor. He had many children; two daughters, Piſidice and Polycaſte; and ſeven ſons, Perſeus, Stratichus, Aretus, Echephron, Piſiſtratus, Antilochus, and Thraſymedes. Neſtor was one of the Argonauts, according to Valerius Flaccus, v. 380, &c.—A poet of Lycaonia in the age of the emperor Severus. He was father to Piſander, who under the emperor Alexander wrote ſome fabulous ſtories——One of the body guards of Alexander.

Nestor, whoſe ſecular name is not known, was a native of Ruſſia, and the earlieſt hiſtorian of the north. He was born in 1056 at Bielozero; and in the 19th year of his age he aſſumed the monaſtic habit in the convent of Petcherſki at Kiof, and took the name of *Neſtor*. He there made a conſiderable proficiency in the Greek [illegible]: but ſeems to have formed his ſtyle and [illegible]nner [illegible]ther from the Byzantine hiſtorians, Cedrenus, [illegible]onar[illegible] and Syncellus, than from the ancient claſſi[illegible] [illegible] time of Neſtor's death is not aſcertained; b[illegible] he [illegible] ſuppoſed to have lived to an advanced age, [illegible] [illegible]ve died about the year 1115.

Neſtor, Neſtorians.

His g[illegible] [illegible] is his Chronicle, to which he has prefixed an introduction, which after a ſhort ſketch of the early ſtate of the world, taken from the Byzantine writers, contains a geographical deſcription of Ruſſia and the adjacent regions; an account of the Sclavonian nations, their manners, their emigrations from the banks of the Danube, their diſperſion, and ſettlements in the ſeveral countries wherein their deſcendants are now eſtabliſhed. He then enters upon a chronological ſeries of the Ruſſian annals, from the year 8[illegible] to about 1113. His ſtyle is ſimple and unadorned, ſuch as ſuits a mere recorder of facts; but his chronological exactneſs, though it renders his narrative d[illegible] and tedious, contributes to aſcertain the era and authenticity of the events which he relates.

It is remarkable (ſays Mr Coxe, from whom we have taken this narrative), that an author of ſuch importance, whoſe name frequently occurs in the early Ruſſian books, ſhould have remained in obſcurity above 600 years; and been ſcarcely known to his modern countrymen, the origin and actions of whoſe anceſtors he records with ſuch circumſtantial exactneſs. A copy of his Chronicle was given in 1668 by Prince Ra[illegible]ivil to the library of Konigſburg, where it lay unnoticed till Peter the Great in his paſſage through the town, ordered a tranſcript of it to be ſent to Peterſburgh. But it ſtill was not known as the performance of Neſtor: for when Muller in 1732 publiſhed the firſt part of a German tranſlation, he mentioned it as the work of the abbot Theodoſius of Kiof; an error which aroſe from the following circumſtance: The ingenious editor not being at that time ſufficiently acquainted with the Sclavonian tongue, employed an interpreter, who, by miſtaking a letter in the title, ſuppoſed it to have been written by a perſon whoſe name was Theodoſius. This ridiculous blunder was ſoon circulated, and copied by many foreign writers, even long after it had been candidly acknowledged and corrected by Muller.

NESTORIANS, a ſect of ancient Chriſtians, ſtill ſaid to be ſubſiſting in ſome parts of the Levant; whoſe diſtinguiſhing tenet is, that Mary is not the mother of God. They take their name from Neſtorius biſhop of Conſtantinople, whoſe doctrines were ſpread with much zeal through Syria, Egypt, and Perſia.

One of the chief promoters of the Neſtorian cauſe was Barſumas, created biſhop of Niſibis, A. D. 435. Such was his zeal and ſucceſs, that the Neſtorians, who ſtill remain in Chaldea, Perſia, Aſſyria, and the adjacent countries, conſider him alone as their parent and founder. By him Pherozes the Perſian monarch was perſuaded to expel thoſe Chriſtians who adopted the opinions of the Greeks, and to admit the Neſtorians in their place, putting them in poſſeſſion of the principal ſeat of eccleſiaſtical authority in Perſia, the ſee of Seleucia, which the patriarch of the Neſtorians has always filled even down to our time.—Barſumas alſo erected a ſchool at Niſibis, from which

Neſtorians.

proceeded thoſe Neſtorian doctors in the fifth and ſixth centuries ſpread abroad the tenets through Egypt, Syria, Arabia, India, Tartar and China.

He differed conſiderably from [illegible], holding that there are two perſons in Jeſus Criſt, as well as that the Virgin was not his mother, as [illegible], but only as man.

The abettors of this doctrine refuſe the title Neſtorians; alleging that it had been handed down from the earlieſt times of the Chriſtian church.

In the tenth century, the Neſtorians in Chaldea, whence they are ſometimes called *Chaldeans*, extended their ſpiritual conqueſts beyond Mount Imaus, and introduced the Chriſtian religion into Tartary properly ſo called, and eſpecially into that country called *Karit*, bordering on the northern part of China. The prince of that country, whom the Neſtorians converted to the Chriſtian faith, aſſumed, according to the vulgar tradition, the name of *John* after his baptiſm, to which he added the ſurname of *Preſbyter*, from a principle of modeſty; whence it is ſaid his ſucceſſors were each of them called *Preſter John* until the time of Gengis Khan. But Moſheim obſerves, that the famous Preſter John did not begin to reign in that part of Aſia before the concluſion of the 11th century. The Neſtorians formed ſo conſiderable a body of Chriſtians, that the miſſionaries of Rome were induſtrious in their endeavours to reduce them under the papal yoke. ent IV. in 1246 and Nicolas IV. in 1278, ed their utmoſt efforts for this purpoſe, but without ceſs. Till the time of Pope Julius III. the Neſtorians acknowledged but one patriarch, who reſided at Bagdad, and afterwards at Mouſul; but a diviſion ariſing among them, in 1551 the patriarchate became divided, at leaſt for a time, and a new patriarch was onſecrated by that pope whoſe ſucceſſors fixed their reſidence in the city of Ormus in the mountainous part of Perſia, where they ſtill continue, diſtinguiſhed by the name of *Simeon*; and ſo far down as the laſt century, theſe patriarchs perſevered in their communion with the church of Rome, but ſeem at preſent to have withdrawn themſelves from it. The great Neſtorian pontiffs, who form the oppoſite party, and look with a hoſtile eye on this little patriarch, have ſince the year 1559 been diſtinguiſhed by the general denomination of Elias, and reſide conſtantly in the city of Mouſul. Their ſpiritual dominion is very extenſive, takes in a great part of Aſia, and comprehends alſo within its circuit the Arabian Neſtorians, and alſo the Chriſtians of St Thomas, who dwell along the coaſt of Malabar. It is obſerved, to the laſting honour of the Neſtorians, that of all the Chriſtian ſocieties eſtabliſhed in the Eaſt, they have been the moſt careful and ſucceſsful in avoiding a multitude of ſuperſtitious opinions and practices that have infected the Greek and Latin churches. About the middle of the 17th century, the Romiſh miſſionaries gained over to their communion a ſmall number of Neſtorians, whom they formed into a congregation or church; the patriarchs or biſhops of which reſide in the city of Amida, or Diarbeker, and all aſſume the denomination of *Joſeph*. Nevertheleſs the Neſtorians in general perſevere to our own times in their refuſal to enter into the communion of the Romiſh church, notwithſtanding the earneſt entreaties and alluring offers that have been made by the pope's legate to conquer their inflexible conſtancy.

Neſtorius.

NESTORIUS, from whom the ſect of Neſtorian Chriſtians derive their name, was born in Germanica a city of Syria. He received his education at Antioch, where he was likewiſe baptized; and ſoon after his baptiſm he withdrew himſelf to a monaſtery in the ſuburbs of that city. Upon his being admitted to the order of prieſtood, he quickly acquired ſo great reputation by the eloquence of his preaching, and the regularity of his life, that by the emperor Theodoſius he was deemed a fit perſon to fill the ſecond ſee in the Chriſtian church, and was accordingly conſecrated biſhop of Conſtantiople in the year 429.

In one of his firſt ſermons after his promotion, he publicly declared his intention to *make war upon heretics*; and with that intolerant ſpirit which has ſo often diſgraced the preachers of the mild religion of Jeſus, he called upon the emperor to *free the earth from heretics*, promiſing to give him heaven as a reward for his zeal. To this ſpiritual motive he added one, that, though carnal, he poſſibly judged of equal force:—“Join with me (ſaid he) in war againſt them, and I will aſſiſt you againſt the Perſians.” Although the wiſer and better part of his audience were amazed to ſee a man, before he had taſted (as the hiſtorian * expreſſes himſelf) the water of his city, declare that he would perſecute all who were not of his opinion; yet the majority of the people approved of this diſcourſe, and encouraged him to execute his purpoſe. Accordingly, five days after his conſecration, he attempted to demoliſh the church in which the Arians ſecretly held their aſſemblies; and he ſucceeded ſo far in his deſign, that theſe people, growing deſperate, ſet it on fire themſelves, and conſumed with it ſome of the neighbouring houſes. This fire excited great commotions in the city, and Neſtorius was ever afterwards called *incendiary*.

From the Arians he turned his perſecution againſt the Novatians, but was ſtopped in his career by the interpoſition of the emperor. He then let looſe his fury thoſe Chriſtians of *Aſia*, *Lydia*, and *Caria*, who celebrated the feaſt of Eaſter upon the 14th day of the moon; and for this unimportant deviation from the Catholic practice, many of thoſe people were murdered by his agents both at Miletum and Sardis.—One cannot be ſorry that ſuch a relentleſs perſecutor ſhould himſelf be afterwards condemned as a heretic, for holding an opinion which no man who ſpeaks or thinks with philoſophic accuracy will now venture to controvert. This obnoxious tenet which produced a ſchiſm in the church, and was condemned by a general council, was nothing more than that “the Virgin Mary cannot with propriety be called the mother of God.” The people being accuſtomed to hear this expreſſion, were much inflamed againſt their biſhop, imagining that he had revived the error of *Paulus Samoſetenus* and *Photinus*, who taught that Jeſus Chriſt was a mere man. The monks declared openly againſt him, and, with ſome of the moſt conſiderable men in Conſtantinople, ſeparated themſelves from his communion. Several biſhops wrote to him earneſt perſuaſives to acknowledge that Mary was the mother of God; and when he would not comply, they procured his condemnation

* *Socrates.*

condemnation in the council of Epheſus, which deprived him of his ſee. He then retired to his ancient monaſtery at Antioch, whence he was taken four years afterwards by the emperor's order, and baniſhed in 435 to Tarſus. That city being taken and deſtroyed by the barbarians, he was removed to Panopolis, a city of Thebais; where he was not ſuffered to remain long, but was compelled to go from place to place, till, being in one of his journeys mortally bruiſed by a fall, death relieved him from the fury of his perſecutors.

If we examine ſuch of his writings as remain, we ſhall find that he was very unjuſtly condemned. It appears that he rejected the errors of *Ebion*, *Paulus Samoſatenus*, and *Photinus;* that he maintained in expreſs terms, that the divine Word was united to the human nature in Jeſus Chriſt in the moſt ſtrict and intimate ſenſe poſſible; that theſe two natures, in this ſtate of union, make but one Chriſt and one perſon; that the properties of the Divine and human natures may both be attributed to this perſon; and that Jeſus Chriſt may be ſaid to have been born of a virgin, to have ſuffered and died; but he never would admit that God could be ſaid to have been born, to have ſuffered, or to have died.—When we conſider that every perſon partakes of the ſubſtance of his mother, and that it is this which conſtitutes the parental and filial relation between them, it is indeed ſurpriſing that the expreſſion "Mother of God" ſhould ever have been admitted into the Chriſtian church, or that any man who underſtands the meaning of the words ſhould condemn Neſtorius for not having uſed them.

NESTUS, or NESSUS, a river which ſeparates Thrace from Macedonia. It falls into the Ægean ſea near the iſland Thaſos. It is ſometimes called *Neſus* and *Neſſus*.

NET, a device for catching fiſh and fowl. See the article FISHERY.

The taking fowls by nets is the readieſt and moſt advantageous of all others, where numbers are to be taken. The making the nets is very eaſy, and what every true ſportſman ought to be able to do for himſelf. All the neceſſary tools are wooden needles, of which there ſhould be ſeveral of different ſizes, ſome round and others flat; a pair of round pointed and flat ſciſſars; and a wheel to wind off the thread. The packthread is to be of different ſtrength and thickneſs, according to the ſort of birds to be taken; and the general ſize of the meſhes, if not for very ſmall birds, is two inches from point to point. The nets ſhould neither be made too deep nor too long, for they are then difficult to manage; and they muſt be verged on each ſide with twiſted thread. The natural colour of the thread is too bright and pale, and is therefore in many caſes to be altered. The moſt uſual colour is the ruſſet; which is to be obtained by plunging the net, after it is made, into a tanners pit, and letting it lie there till it be ſufficiently tinged: this is of a double ſervice to the net, ſince it preſerves the thread as well as alters the colour. The green colour is given by chapping ſome green wheat and boiling it in water, and then ſoaking the net in this green tincture. The yellow colour is given in the ſame manner with the decoction of celandine; which gives a pale ſtraw-colour, which is the colour of ſtubble in the harveſt-time. The brown nets are to be uſed on ploughed lands, the green on graſs grounds, and the yellow on ſtubble lands.

NET-Day, among fowlers, a net generally uſed for taking ſuch ſmall birds as play in the air, and will ſtoop either to prey, gig, or the like; as larks, linnets, buntings, &c. The time of the year for uſing this net is from Auguſt to November; and the beſt time is very early in the morning: and it is to be obſerved, that the milder the air, and the brighter the ſun is, the better will be the ſport, and of longer continuance. The place where this net ſhould be laid, ought to be plain champaign, either on ſhort ſtubbles, green lays, or flat meadows, near corn fields, and ſomewhat remote from towns and villages: you muſt be ſure to let your net lie cloſe to the ground, that the birds creep not out and make their eſcape.—The net is made of a fine packthread with a ſmall meſh, not exceeding half an inch ſquare; it muſt be three fathoms long, and but one broad: it muſt be verged about with a ſmall but ſtrong cord; and the two ends extended upon two ſmall long poles, ſuitable to the breadth of the net, with four ſtakes, tail-ſtrings, and drawing-lines.—This net is compoſed of two, which muſt be exactly alike; and are to be laid oppoſite to one another, ſo even and cloſe, that when they are drawn and pulled over, the ſides muſt meet and touch each other. You muſt ſtake this net down with ſtrong ſtakes, very ſtiff on their lines, ſo that you may with a nimble touch caſt them to and fro at pleaſure; then faſten your drawing-cord or hand-lines (of which there muſt be a dozen at leaſt, and each two yards long) to the upper end of the foremoſt ſtaves: and ſo extend them of ſuch a ſtraitneſs, that with a little ſtrength they may riſe up in the nets and caſt them over.

Sportſman's Dict.

Your nets being thus laid, place you gigs, or playing-wantons, about 20 or 30 paces beyond, and as much on this ſide your nets: the gigs muſt be faſtened to the tops of long poles, and turned into the wind, ſo as they may play to make a noiſe therein. Theſe gigs are a ſort of toys made of long gooſe-feathers, like ſhuttle-cocks, and with little ſmall tunnels of wood running in broad and flat ſwan-quills, made round like a ſmall hoop; and ſo, with longer ſtrings faſtened to a pole, will, with any ſmall wind or air, move after ſuch a manner, that birds will come in great flocks to play about them.

When you have placed your gigs, then place your ſtale; which is a ſmall ſtake of wood, to prick down into the earth, having in it a mortice-hole, in which a ſmall and ſlender piece of wood, about two feet long, is faſtened, ſo as it may move up and down at pleaſure: and faſten to this longer ſtick a ſmall line, which, running through a hole in the ſtick abovementioned, and ſo coming up to the place where you are to ſit, you may, by drawing the line up and down with your right hand, raiſe up the longer ſtick as you ſee occaſion.

Faſten a live lark, or ſuch like bird, to this longer ſtick, which, with the line making it to ſtir up and down by your pulling, will entice the birds to come to your net.

There is another ſtale, or enticement, to draw on theſe birds, called a *looking glaſs;* which is a round ſtake of wood, as big as a man's arm, made very ſharp at the end, to thruſt it into the ground: they make it very hollow in the upper part, above five fingers deep; into which hollow they place a three-ſquare piece of wood about a foot long, and each two inches broad, lying upon the top of the ſtake, and going with a foot into the hollowneſs: which foot muſt have a great knob at the top, and another at the bottom, with a deep ſlenderneſs between; to which ſlenderneſs you are to faſten a ſmall packthread, which, running through a hole in the ſide of the ſtake, muſt come up to the place where you ſit. The three-ſquare piece of wood which lies on the top of the ſtake, muſt be of ſuch a poiſe and evenneſs, and the foot of the ſocket ſo ſmooth and round, that it may whirl and turn round upon the leaſt touch; winding the packthread ſo many times about it, which being ſuddenly drawn, and as ſuddenly let go, will keep the engine in a conſtant rotatory motion: then faſten with glue on the uppermoſt flat ſquares of the three-ſquare piece, about 20 ſmall pieces of looking-glaſs, and paint all the ſquare wood between them of a light and lively red; which, in the continual motion, will give ſuch a reflection, that the birds will play about to admiration until they are taken.

Both this and the other ſtale are to be placed in the middle between the two nets, about two or three feet diſtance from each other; ſo that, in the falling of the nets, the cords may not touch or annoy them: neither muſt they ſtand one before or after another; the glaſs being kept in a continual motion, and the bird very often fluttering. Having placed your nets in this manner, as alſo your gigs and ſtales, go to the further end of your long drawing lines and ſtale lines; and, having placed yourſelf, lay the main drawing line acroſs your thigh, and, with your left, pull the ſtale line to ſhow the birds; and when you perceive them to play near and about your nets and ſtales, then pull the net over with both hands, with a quick but not too haſty motion; for otherwiſe your ſport will be ſpoiled.

See Plate CCCXLV. where A ſhows the bodies of the main net, and how they ought to be laid. B, the tail lines, or the hinder lines, ſtaked to the ground. C, the fore lines ſtaked alſo to the ground. D, the bird ſtale. E, the looking-glaſs ſtale. G, the line which draws the bird ſtale. H, the line that draws the glaſs ſtale. I, the drawing, double lines of the nets, which pulls them over. K, the ſtakes which ſtake down the four nether points of the nets and the two tail lines. L, the ſtakes that ſtake down the fore lines. M, the ſingle line, with the wooden button to pull the net over with. N, the ſtake that ſtakes down the ſingle line, and where the man ſhould ſit; and O, the gig.

Net, *Neat*, in commerce, ſomething pure, and unadulterated with any foreign mixture.

Thus, wines are ſaid to be *net* when not falſified or balderdaſhed; and coffee, rice, pepper, &c. are *net* when the filth and ordures are ſeparated from them. See Neat.

A diamond is ſaid to be *net* when it has no ſtains or flaws; a cryſtal, when tranſparent throughout.

Net is alſo uſed for what remains after the tare has been taken out of the weight of any merchandiſe, *i. e.* when it is weighed clear of all package. See Tare.

Thus we ſay, a barrel of cochineal weighs 450 pounds; the tare is 50 pounds, and there remain *net* 400 pounds.

Net Produce, a term uſed to expreſs what any commodity has yielded, all tare and charges deducted.

The merchants ſometimes uſe the Italian words *netto proceduto*, for net produce.

NETHERLANDS, anciently called *Belgia*, but ſince denominated *Low Countries* or *Netherlands*, from their low ſituation, are ſituated between 2° and 7° of eaſt longitude, and between 50° and 53° 30′ of north latitude: and are bounded by the German ſea on the north, Germany on the eaſt, by Lorrain and France on the ſouth, and by another part of France and the Britiſh ſeas on the weſt; extending near 300 miles in length from north to ſouth, and 200 miles in breadth from eaſt to weſt. They conſiſt of 17 provinces; 10 of which are called the *Auſtrian and French Netherlands*, and the other ſeven the *United Provinces*.

The greateſt part of the Netherlands was conquered by the Romans; and that part which lies towards Gaul continued in their ſubjection till the decline of that empire; after which the Francs became maſters of it; and, under the French monarchy, it was part of the kingdom of Metz or Auſtraſia.

Towards the end of the 15th century Maximilian of Auſtria, ſon of the emperor Ferdinand III. acquired, by marrying the only daughter of the duke of Burgundy, the duchies of Brabant, Limburg, and Luxemburg; the counties of Flanders, Burgundy, Hainault, Holland, Zealand, and Namur; and the lordſhips of Frieſland. Philip of Auſtria, ſon to Maximilian and Mary, married Jane the daughter of Ferdinand king of Arragon, and of Iſabella queen of Caſtile; by which means their ſon Charles inherited not only almoſt all Spain and the great countries then lately diſcovered in America, but alſo thoſe noble provinces of the Netherlands, and was choſen emperor under the name of *Charles V.* Towards the latter end of the 1527, he added to his dominions the temporalities of the biſhoprick of Utrecht on both ſides of the Yſſel; and Henry of Bavaria, being diſtreſſed through war with the duke of Guelderland, and tired with the continued rebellion of his own ſubjects, ſurrendered to the emperor the temporalities of his dioceſe, which was confirmed by the pope, and the ſtates of the country. In 1536, Charles V. bought of Charles of Egmond the reverſion of the duchy of Guelderland and of the county of Zutphen, in caſe that prince ſhould die without iſſue. The ſame year the city of Groningen took the oath of allegiance, and ſubmitted to Charles V. and in 1543 he put a garriſon into the city of Cambray, and built a citadel there. Having thus united the 17 provinces, as it were in one body, he ordered that they ſhould continue for ever under the ſame prince, without being ever ſeparated or diſmembered; for which purpoſe he publiſhed in November 1549, with the conſent and at the requeſt of the ſtates of all the provinces, a perpetual and irrevocable edict or law, by which it was enacted, that in order to keep all thoſe provinces together under one and the ſame prince, the right of repreſentation, with regard to the ſucceſſion of a prince or princeſs, ſhould take place for ever, both in a direct and collateral line, notwithſtanding the common laws of ſome provinces to the contrary. Charles had even a mind to incorporate theſe provinces with the Germanic body, and to make of them a circle of the empire, under the title of the circle of Burgundy, in order thereby to engage princes of the empire to concern themſelves for the preſervation of thoſe provinces. But the Netherlands, always jealous of their liberty, did not ſeem to like that incorporation; and when they were demanded to pay their ſhare towards the expences of the empire, they refuſed it: whereupon the princes of Germany refuſed, in their turn, to take any part in the wars in Flanders, and looked upon thoſe provinces as by no means belonging to the Germanic body.

Philip of Auſtria and his ſon Charles, who were born in the Netherlands, had for theſe provinces that natural affection which men uſe to have for their native country; and, knowing how jealous the inhabitants were of their liberty, and of the privileges granted to them by their former princes, they took great care to preſerve them, and ſuffered willingly that the ſtates, who were the guardians of the people's liberty and privileges, ſhould in a manner ſhare the ſupreme authority with them. Philip II. ſon to the emperor Charles V. had not the ſame affection for the Netherlands, nor thoſe generous ſentiments which his father had endeavoured to inſpire him with. Being born in Spain of a Portugueſe woman, he had no regard but for his native country; and, when he removed out of the Netherlands, he left them to the weak government of a woman, to the proud and haughty ſpirit of Cardinal de Grenville, and to the wild ambition of ſome lords of theſe provinces, who availing themſelves of the imprudent conduct and continual blunders of the council of Spain, found their private intereſt in the diſturbances they could not fail to produce. Philip II. alſo, inſtead of the mild and moderate meaſures which his predeceſſors had ſucceſsfully employed on many occaſions, as beſt ſuiting the genius and temper of the people, had recourſe to the moſt violent and cruel proceedings; which, far from curing the evil, ſerved only to exaſperate it the more and render it incurable. The Spaniards, whom he ſent hither, being born and educated in an abſolute monarchy, jealous of the liberties and envious of the riches of the people, broke through all their privileges, and uſed them almoſt after the ſame manner as they had done the inhabitants of their new and ill-gotten dominions in America. This treatment occaſioned a general inſurrection. The counts Hoorn, Egmont, and the prince of Orange, appearing at the head of it, and Luther's reformation gaining ground about the ſame time in the Netherlands, his diſciples joined the malecontents: whereupon King Philip introduced a kind of inquiſition in order to ſuppreſs them, and many thouſands were put to death by that court, beſides thoſe that periſhed by the ſword: for theſe perſecutions and encroachments had occaſioned a civil war, in which ſeveral battles were fought. The counts Hoorn and Egmont were taken and beheaded: but the prince of Orange, retiring into Holland, did, by the aſſiſtance of England and France, preſerve Holland and ſome of the adjacent provinces, which entered into a treaty for their mutual defence at Utrecht in 1579, and they have ever ſince been ſtyled the *United Provinces*; but the other provinces were reduced to the obedience of Spain by the duke of Alva and other Spaniſh generals. However, their ancient privileges were in a great meaſure reſtored; every province was allowed its great council or parliament, whoſe concurrence was required to the making of laws, and raiſing money for the government, though theſe aſſemblies were too often obliged to follow the dictates of the court.

The late emperor Joſeph II. endeavoured to deprive them even of the form of their free conſtitution; and he might very probably have ſucceeded, had he not attempted at the ſame time a reformation of the church. The Auſtrian Netherlands are wholly Catholic, and ſo bigotted to the Romiſh ſuperſtition, that though they had tamely ſubmitted to many encroachments of the archducal houſe on their civil right, no ſooner did the monarch encroach upon the property of the holy mother church than they reſiſted his authority, and claimed all their ancient privileges political and religious. The ſame attachment to their ancient faith and worſhip made them very lately contribute to expel from their territories the French whom they had invited to relieve them from the Auſtrian yoke. Thus her religious bigotry for once ſaved a free people from the iron rod of deſpotiſm on the one hand, and the cruelties of frantic democrates on the other. The provinces under the government of France were, till the late revolution, under the ſame ſevere arbitrary dominion as the other ſubjects of that crown, and they now experience the ſame miſeries with the reſt of the republic.

The Spaniards continued poſſeſſed of almoſt eight of theſe provinces, until the duke of Marlborough, general of the allies, gained the memorable victory of Ramillies. After which Bruſſels the capital, and great part of theſe provinces, acknowledged Charles VI. (afterwards emperor) their ſovereign; and his daughter, the late empreſs queen, remained poſſeſſed of them till the war that followed the death of her father, when the French made an entire conqueſt of them, except part of the province of Luxemburg; but they were reſtored by the peace of Aix-la-Chapelle in 1748, and the French retained only Artois, the Cambreſis, part of Flanders, part of Hainault, and part of Luxemburg, of which they have had the dominion now upwards of eighty years.

The ſoil is generally fruitful, but differs in the ſeveral parts. The climate alſo differs in the ſeveral provinces; in thoſe towards the ſouth it does not differ much from that of England, though the ſeaſons are more regular. In the northern provinces the winter is generally very ſharp, and the ſummer ſultry hot; but the extreme cold and exceſſive heat ſeldom continue above five or ſix weeks. The air is reckoned very wholeſome, but is ſubject to thick fogs in winter, through the moiſtneſs of the country, which would be very noxious, were it not for the dry eaſterly winds, which, blowing off a long continent for two or three months in the year, clear the air, and occaſion very ſharp froſts in January and February; during which, the ports, rivers, and canals, are commonly ſhut up The face of the country is low and flat; for, except ſome ſmall hills and a few riſing grounds in Utrecht and Guelderland, and in the parts lying towards Germany, there is no hill to be ſeen in the whole 17 provinces. This is the reaſon that they have been called the Low Countries. French Flanders abounds in grain, vegetables, flax, and cattle, but is in want of wood.

For the *Dutch Netherlands*, ſee *United Provinces*.

NETHINIMS, among the Jews, the poſterity of the Gibeonites, who were condemned by Joſhua to be hewers of wood and drawers of water for the houſe of God.

NETOPION, a name given by the ancients to a very fragrant and coſtly ointment, conſiſting of a great number of the fineſt ſpicy ingredients. Hippocrates, in his Treatiſe of the Diſeaſes of Women, frequently preſcribes the netopion in diſeaſes of the uterus; and in other places he ſpeaks of its being poured into the ear as a remedy for deafneſs; theſe compoſitions, by their attenuating qualities, dividing the viſcous and thick humours. The word *netopion* is alſo ſometimes uſed to expreſs the *unguentum Ægyptiacum*, and ſometimes ſimply for oil of almonds.

NETSCHER (Gaſpard), an eminent painter, born at Prague in Bohemia in 1639. His father dying while he was an engineer in the Poliſh ſervice, his mother was obliged, on account of her religion, ſuddenly to leave Prague with her three ſons. When ſhe had proceeded three leagues, ſhe ſtopped at a caſtle; which being ſoon after beſieged, two of her ſons were ſtarved to death; but ſhe herſelf found means to eſcape out of the fortreſs by night, and to ſave her only remaining child. Carrying him in her arms, ſhe reached Arnheim in Guelderland, where ſhe found means to ſupport herſelf, and breed up her ſon. At length a doctor of phyſic took young Netſcher into his patronage, with the view of giving him an education proper for a phyſician: but Netſcher's genius leading him to painting, he could not forbear ſcrawling out deſigns upon the paper on which he wrote his themes; and it being found impoſſible to conquer his fondneſs for drawing, he was ſent to a glazier, who was the only perſon in the town that underſtood drawing. Netſcher ſoon finding himſelf above receiving any farther aſſiſtance from his maſter, was ſent to Deventer, to a painter named *Terburg*, who was an able artiſt and a burgomaſter of the town; and having acquired under him a great command of his pencil, went to Holland, where he worked a long time for the dealers in pictures, who paid him very little for his pieces, which they ſold at a high price. Diſguſted at this ungenerous treatment, he reſolved to go to Rome; and for that purpoſe embarked on board a veſſel bound for Bourdeaux. But his marrying in that city prevented his travelling into Italy; and therefore, returning into Holland, he ſettled at the Hague; where obſerving that portrait-painting was the moſt profitable, he applied himſelf ſolely to it, and acquired ſuch reputation, thas there is not a conſiderable family in Holland that has not ſome of his portraits; and beſides, the greateſt part of the foreign miniſters could not think of quitting Holland without carrying with them one of Netſcher's portraits, whence they are to be ſeen all over Europe. He died at the Hague, in 1684; leaving two ſons, Theodore and Conſtantine Netſcher, both of them good portrait painters.

NETTINGS, in a ſhip, a ſort of grates made of ſmall ropes ſeized together with rope yarn or twine, and fixed on the quarters and in the tops; they are ſometimes ſtretched upon the ledges from the waſte-trees to the roof trees, from the top of the forecaſtle to the poop, and ſometimes are laid in the waſte of a ſhip to ſerve inſtead of gratings,

NETTLE, in botany. See Urtica.

Sea Nettle. See Medusa and *Animal-Flower*.

Nettle-Tree. See Celtis.

NETTUNO, a handſome town of Italy, in the Campagna di Roma. It is but thinly peopled, though ſeated in a fertile ſoil. The inhabitants are almoſt all hunters. E. Long. 12. 57. N. Lat. 41. 30.

NEVA, a river at Peterſburgh, in Ruſſia. The views upon the banks exhibit the moſt grand and lively ſcenes. The river is in moſt places broader than the Thames at London. It is deep, rapid, and tranſparent as cryſtal, and its banks are lined on each ſide with a continued range of handſome buildings. On the north ſide the fortreſs, the academy of ſciences and that of art are the moſt ſtriking objects; on the oppoſite ſide are the imperial palace; the admiralty, the manſions of many Ruſſian nobles, and the Engliſh line, ſo called becauſe (a few houſes excepted) the whole row is occupied by the Engliſh merchants. In front of theſe buildings, on the ſouth ſide, is the quay, which ſtretches for three miles, except where it is interrupted by the admiralty; and the Neva, during the whole of that ſpace, has been lately embanked at the expence of the empreſs by a wall, parapet, and pavement of hewn granite; a moſt elegant and durable monument of imperial munificence. There is a communication between the oppoſites ſides of the river by a bridge of pontoons, which, when any thing is apprehended from the force of ice ruſhing down the ſtream, can be, and is generally indeed, removed. The great depth of the river, it appears, prevents the building of a ſtone bridge; and, if it could be built, there is no reaſon to ſuppoſe it could poſſibly reſiſt the force of thoſe vaſt ſhoals of ice which in the beginning of winter come down this rapid river. An attempt, however, has been made to remedy this inconvenience; and a Ruſſian peaſant has actually projected the plan of throwing a wooden bridge of one arch acroſs it, which in its narroweſt part is 980 feet in breadth. As we think this is a matter of very conſiderable importance, as well as of curioſity, we ſhall give the following copious account of the plan and its author, in Mr Coxe's own words; who tells us that the artiſt had then executed a model 98 feet in length, which he ſaw and examined with conſiderable attention.

"The bridge is upon the ſame principle with that of Shaffhauſen, excepting that the mechaniſm is more complicated, and that the road is not ſo level. I ſhall attempt to deſcribe it by ſuppoſing it finiſhed, as that will convey the beſt idea of the plan. The bridge is roofed at the top, and covered at the ſides; it is formed by four frames of timber, two on each ſide, compoſed of various beams or truſſes, which ſupport the whole machine. The road is not, as is uſual, carried over the top of the arch, but is ſuſpended in the middle.

"The following proportions I noted down with the greateſt exactneſs at the time when they were explained to me by the artiſt.

Length of the abutment on the north end,	658 feet.
Span of the arch, - - -	980
Length of the abutment on the ſouth end,	658
Length of the whole ſtructure, including the abutments, - -	2296
The plane of the road upon its firſt aſcent makes an angle of five degrees with the ordinary ſurface of the river.	
Mean level of the river to the top of the bridge in the centre, -	168
Ditto to the bottom of the bridge in the centre, - -	126
Height of the bridge from the bottom to the top in the centre, - -	42
Height from the bottom of the bridge in the centre to the road, -	7
Height from the bottom of ditto to the water, - -	84
Height from the water to the ſpring of the arch, - - -	56

So that there is a difference of 35 feet between the road at the ſpring of the arch and the road at the centre; in other words, an aſcent of 35 feet in half 980, or in the ſpace of 490 feet, which is little more than eight-tenths of an inch to a foot. The bridge is broadeſt towards the ſides, and diminiſhes towards the centre.

In the broadeſt part it is -	168 feet.
In the centre or narroweſt -	42
The breadth of the road is -	28

"The artiſt informed me, that to complete the bridge would require 49,650 iron nails, 12,908 large trees, 5500 beams to ſtrengthen them, and that it would coſt 300,000 roubles, or £60,000l. He ſpeaks of this bold project with the uſual warmth of genius; and is perfectly convinced that it would be practicable. I muſt own that I am of the ſame opinion, though I hazard it with great diffidence. What a noble effect would be produced by a bridge ſtriking acroſs the Neva, with an arch 980 feet wide, and towering 168 feet from the ſurface of the water? The deſcription of ſuch a bridge ſeems almoſt chimerical; and yet upon inſpection of the model we become reconciled to the idea. But whether the execution of this ſtupendous work may deemed poſſible or not, the model itſelf is worthy of attention, and reflects the higheſt honour on the inventive faculties of that unimproved genius. It is ſo compactly conſtructed, and of ſuch uniform ſolidity, that it has ſupported 3540 pood, or 127,440 pounds, without having in the leaſt ſwerved from its direction, which I am told is far more, in proportion to its ſize, than the bridge if completed would have occaſion to ſuſtain from the preſſure of the carriages added to its own weight.

"The perſon who projected this plan is a common Ruſſian peaſant. This extraordinary genius was apprentice to a ſhopkeeper at Niſhnei Novogorod: oppoſite to his dwelling was a wooden clock, which excited his curioſity. By repeated examinations he comprehended the internal ſtructure, and without any aſſiſtance formed one exactly ſimilar in its proportion and materials. His ſucceſs in this firſt eſſay urged him to undertake the conſtruction of metal clocks and watches. The empreſs, hearing of theſe wonderful exertions of his native genius, took him under her protection, and ſent him to England; from whence, on account of the difficulties attending his ignorance of the language, he ſoon returned to Ruſſia. I ſaw a repeating watch of his workmanſhip at the Academy of Sciences: it is about the bigneſs of an egg; in the inſide is repreſented the tomb of our Saviour, with the ſtone at the entrance, and the centinels upon duty: ſuddenly the ſtone is removed, the centinels fall down, the angels appear, the women enter the ſepulchre, and the ſame chant is heard which is performed on Eaſter-eve. Theſe are trifling, although curious performances; but the very planning of the bridge was a moſt ſublime conception. This perſon, whoſe name is *Kulibin*, bears the appearance of a Ruſſian peaſant; he has a long beard, and wears the common dreſs of the country. He receives a penſion from the empreſs, and is encouraged to follow the bent of his mechanical genius (A)."

NEVEL, or NEBEL, in the Jewiſh antiquities, a kind of muſical inſtrument. See NABLUM. Plate CCCXLIV.

NEVERS is the capital of the Nevernois in France, and government of Orleanois. It is ſituated in E. longitude 3. 15. N. latitude 46. 50. on the river Loire, which here receives the rivulet *Nievre*, from which this city derives its name. It is a place of great antiquity, ſuppoſed to be Cæſar's Noviodunum in Æduis, where he erected magazines for his armies. Francis I. made it a duchy and peerage in 1521, in favour of Francis of Cleve, to whom it came by marriage. It devolved afterwards to the houſe of Mantua, and then to the Palatine family, who 1651 ſold it to Cardinal Mazarine. The cardinal obtained a title of duke and peer for his nephew Philip Mancini, in whoſe family it continued till the late revolution, though it is impoſſible, in the preſent unſettled ſtate of France, to ſay whoſe property it may be now. The town is fortified with walls, defended with many high towers and deep ditches, and is the ſeat of a biſhopric, ſuffragan of Sens, as likewiſe of a bailiwic and chamber of accounts.

(A) We have given this detail in Mr Coxe's own words, as it appears to us to deſerve attention on account of the greatneſs of the project, which would have excited admiration had it been attempted by one enlightened by ſcience and liberal arts, much more when it comes through the humble medium of a Ruſſian peaſant. It was never executed, as we are juſt informed by a gentleman who left St Peterſburgh about the beginning of June 1793; but the model remains, and is ſtill ſhown. The ſame gentleman (we quote his own words) adds, "that every mechanic thinks it practicable; and that the general belief is, that the empreſs would have built it, had ſhe not found uſe for all her money in carrying on her warlike and diplomatic tranſactions with other courts."

counts. There is a ſtone bridge on the Loire, with twenty arches, a draw-bridge on each ſide, and towers to defend them. The cathedral is dedicated to St Cyr. There are eleven pariſhes in the town, and a great many religious houſes. The Jeſuits college near the gate des Ardeliers is a handſome ſtructure. The palace of the dukes of Nevers has a large front between two great towers, with a court on one ſide and a garden on the other. Here it was that John Caſimir king of Poland died the 16th of December 1672. Near this palace ſtands the convent of Cordeliers, who have a magnificent church, in which the tombs of duke John and Catharine of Bourbon on the right, and thoſe of Lewis of Gonzaga duke of Nevers, and Henrietta of Cleves his wife, merit attention.—— This town is famous for its glaſs-manufacture and earthen ware, and is ſaid to contain about 8000 inhabitants.

In the centre of Nevers, on the ſummit of a hill, is built the palace of the ancient dukes. It appears to have been conſtructed in the ſixteenth century, and, though beginning to exhibit marks of decay, is yet a model of the beauty and delicacy of the Gothic architecture. The apartments are hung with tapeſtry of 200 years old, which have an air of groteſque and rude magnificence. There is in one of the chambers a portrait of Madame de Monteſpan, who appears riſing from a ſuperb couch, the curtains of which are drawn back, and ſupported by Cupids. Her attitude is half voluptuous, half contemplative. She is dreſſed in a negligent diſhabille, and her hair floats down over her ſhoulders and neck in waving ringlets. Her head reſts on her left hand, and one of her feet is concealed by her robe; the other, which is naked to the mid-leg, and on which the painter with great taſte, has exhauſted all his art, is placed on an embroidered cuſhion. Her ſlippers are thrown careleſsly by.

NEUCHATTEL, a tolerably handſome town of Swiſſerland, capital of a county of the ſame name. There are ſeveral ancient ruins near it, which ſhow its former extent; and there are two large churches, beſides a caſtle where the governor reſides. The town contains about 3000 inhabitants. It is ſituated partly on a ſmall plain, between Mount Jura and the lake of Neuchattel, which is 17 miles long and five broad; the ſide of the harbour is the uſual walk of the inhabitants. Part of it too is built upon the ſide of the mountain; whence ſome of its ſtreets are very ſteep. In this ſmall place ſeveral public works have lately been executed, which Mr Coxe thinks are far beyond the revenues, or even the wants, of ſuch a little ſtate. Among theſe he inſtances a ſuperb cauſeway and a town-houſe "built (ſays he) of ſuch ſolid materials as if it was intended to ſurvive to the moſt diſtant poſterity, and to rival the duration of the much-famed Roman capitol." At the beginning of the preſent century, commerce was very little followed in this town, owing to an abſurd opinion which prevailed among the inhabitants of its being diſgraceful; but this prejudice is now extinguiſhed, and the town in a much more flouriſhing ſituation than before. The chief article of exportation is wine, which is much eſteemed; and manufactures of printed linens and cotton have been eſtabliſhed with conſiderable ſucceſs. The flouriſhing ſtate of Neuchattel is principally owing to the benefactions of Mr David Pury, late banker of the court at Liſbon. He was born at Neuchattel in 1709; but having received his education there, he quitted it in great poverty and repaired to Geneva, where he ſerved his apprenticeſhip, but in what line is not mentioned. From Geneva he went to London, where he acted as clerk to a dealer in precious ſtones, and acquired great reputation by eſtimating the value of diamonds at ſight. After a long reſidence in England he went to Liſbon, where he carried on a very extenſive commerce: and having been appointed court-banker, his fortune rapidly increaſed. His generoſity, however, kept pace with his wealth; and he not only remitted large ſums to Neuchattel while living, but left his country his heir when he died. His contributions in all are eſtimated by Mr Coxe at 200,000l.; a conſiderable part of which has been employed in conſtructing the public works already mentioned. Mr Coxe hints, that notwithſtanding the ſuperb edifices already mentioned, there are many conveniencies ſtill wanting to render Neuchattel agreeable; the public walks, for inſtance, might be greatly improved; the ſtreets, which are very dirty, might be kept clean; and a torrent which runs through the town, and frequently threatens it with inundations, might be turned. Encouragement ought alſo to be given to literature; for our author obſerves, that the inhabitants of Neuchattel are much more ignorant than thoſe of other parts in Swiſſerland, which no doubt is in a great meaſure owing to their having not a ſingle ſeminary of learning which deſerves the name in the place. It has a grand and little council: the firſt is compoſed of 40 perſons, with two maſters of the keys; the little council conſiſts of 24 members, comprehending the mayor, who is preſident. Theſe two councils aſſemble regularly every month. The eccleſiaſtics likewiſe aſſemble every month, to conſult on affairs belonging to the church, and to fill up the places of miniſters that die. They chooſe a dean every year, who is preſident of the general aſſemblies, which are called *claſſes*; and ſometimes he is confirmed in this dignity. E. Long. 7. 10. N. Lat. 47. 5.

NEUCHATTEL, a ſovereign county of Swiſſerland, bounded on the weſt by the Franche Compte, on the north by the biſhopric of Baſle, and on the eaſt and ſouth by the cantons of Berne and Friburg. This principality of Neuchattel and Vallengin extend from the lake of Neuchattel to the borders of Franche Compte, being in length about 12 leagues, and ſix in breadth. The plain with the lower part of the mountains is occupied by the diſtrict of Neuchattel, but Vallengin is totally encloſed by Jura. Parallel chains of theſe mountains run from eaſt to weſt, forming ſeveral valleys in the moſt elevated parts. The lower grounds of this chain conſiſt of arable lands and vineyards; the higher of large tracts of foreſt, which in many parts have been cleared and converted into paſture grounds, intermixed with fields of barley and oats. The inhabitants are numerous, and remarkable for their genius, politeneſs, and active induſtry. It contains three cities, one town, 90 villages, and about 300 houſes diſperſed in the mountains. The inhabitants are all Proteſtants, except two Roman catholic villages: and in 1529 they entered into a ſtrict alliance with the cantons of Berne, Friburg, Soleure, and Lucern. The air is healthy and temperate, but the ſoil not everywhere equally fertile: however, there are large vineyards, which produce white and red wine, which laſt is excellent. The paſtures on the mountains feed a great number of all ſorts of cattle; and there are plenty of deer in the foreſts; beſides large trouts, and other good fiſh, in the lakes and rivers. The mildneſs of the government, and agreeable ſituation of the inhabitants in general in theſe diſtricts, is evident from the great increaſe of population in the ſpace of 32 years. In 1752 they contained only 28,017 ſubjects and 4318 aliens: but in 1784 the number was augmented to 31,576 ſubjects and 9704 aliens; being an increaſe of near a fourth part in that time. The facility with which the burgherſhip of Neuchattel is acquired, may alſo be accounted one of the means of augmenting its population; for between the years 1760 and 1770, the magiſtrates admitted 41 perſons to this privilege; from 1770 to 1780, 46; from 1780 to 1785, 51; in all 138; many of whom had children before they purchaſed their burgherſhip, and 38 of them were foreigners, either German, French, or Dutch.

The diſtricts of Neuchattel and Vallengin now make part of the Pruſſian dominions. It had its own counts for a long time; the laſt of whom dying in 1694 without iſſue, it came to Mary of Orleans ducheſs of Nemours, his only ſiſter, who alſo died without iſſue in 1703. There were then 13 competitors, among whom was Frederick I. king of Pruſſia, who claimed as heir to the prince of Orange. His right was acknowledged by the ſtates of the country in 1707; but in this part of his dominions the Pruſſian monarch is far from having ſuch an abſolute authority as in others. On the acceſſion of Frederick I. ſome general articles were agreed on, by which the prerogatives of the prince and the rights of the people were ſettled. Diſputes, however, occurred betwixt the king and his ſubjects, which were not thoroughly ſettled till the year 1768, when the general articles were not only renewed, but explained wherever their tenor had been miſtaken, confirming alſo ſeveral privileges in favour of the people which had hitherto been equivocal or not duly obſerved. The moſt important of theſe general articles were, 1. The eſtabliſhment of the reformed religion, and the toleration of no other, except in two places where it was already prevalent. 2. No civil or military office to be poſſeſſed by foreigners, that of governor only excepted. 3. All ſubjects have a right to enter into the ſervice of a foreign prince not actually at war with the king as ſovereign of Neuchattel; the ſtate may alſo continue neuter when the king is engaged in wars which do not concern the Helvetic body. 4. The proper adminiſtration of juſtice; for which the three eſtates of Neuchattel and Vallengin ſhall be annually aſſembled. 5. The magiſtrates to hold their places during good behaviour; but of this certain perſons appointed at Neuchattel, and not the king, are to judge. 6. The ſovereign, on his acceſſion, ſhall take an oath to maintain the rights, liberties, and cuſtoms of the people, *written* and *unwritten*.

This laſt article is no leſs important than it is ſingular; for upon an unwritten cuſtom one of their moſt eſſential privileges depends; viz. that the ſovereign ſhall be conſidered only as reſident at Neuchattel. "Now (ſays Mr Coxe), this privilege, in conjunction with the third article juſt cited, forms the baſis of their civil liberty. By the former, the prince, when abſent, can only addreſs his ſubjects through his governor and the council of ſtate; and no ſubject can be tried out of the country, or otherwiſe than by judges appointed by the conſtitution: by the latter, ſhould the king of Pruſſia be at war with all Germany, the people of Neuchattel and Vallengin are by no means obliged to arm in his defence; but individuals may even ſerve againſt him, as long as the powers whom they ſerve are not engaged in any hoſtilities againſt their own country." A remarkable inſtance of this laſt our author gives in the following anecdote. "When Henry duke of Longueville, and ſovereign of Neuchattel was, in 1650, ſent to the caſtle of Vincennes, Felix de Mareval, captain of the Swiſs guards, kept guard in his turn, though he was citizen of Neuchattel, at the door of the priſon where his ſovereign was confined."

The king confers nobility, names the principal officers of ſtate, appoints the preſidents of the courts of juſtice called *chatelins* and *mayors*; but his revenues ſcarcely amount to 5000l. a-year. They ariſe from certain demeſnes; from a ſmall land-tax, the tythes of wine and corn, and a tenth part of the value of all immoveables. No ſubject pays any duty upon goods either exported or imported, except for foreign wines brought into the town itſelf.

Neuchattel enjoys very conſiderable privileges, has the care of the police within its own diſtrict, and is governed by its own magiſtracy conſiſting of a great and little council. The three eſtates of the country form the ſupreme tribunal, and receive appeals from the inferior court of juſtice. They conſiſt of 12 judges divided into three eſtates: the judges in the firſt and ſecond diviſion hold their places for life; but thoſe in the third are choſen annually. The eſtates uſually meet once a-year in the month of May, but are convoked extraordinarily upon particular occaſions, and the town of Neuchattel is always the place of meeting. They are not, however, the repreſentatives of the people, nor do they poſſeſs any legiſlative authority. Properly ſpeaking, they are the ſupreme court of judicature, which receives all appeals, and decides finally upon all cauſes, even thoſe which relate to the ſovereignty of the country, of which we have an example in the revolution of 1707. The ordinary adminiſtration of government is veſted in the council of ſtate, which ſuperintends the general police, and is the medium by which the ſovereign exerciſes his juriſdiction. The members are nominated by the king, and are not reſtricted to any number, but he is always conſidered as perſonally preſiding in the aſſembly; and the preſident has no other powers than thoſe of convoking the aſſembly, propoſing the ſubjects of conſideration, collecting the votes, and deciding when the voices are equal. The ordinances of this council are previouſly communicated to the *miniſtraux* of Neuchattel, who muſt certify that they contain nothing contrary to law. The miniſtraux are a kind of committee from the council of the town, and are intruſted with the adminiſtration of the police. They conſiſt of the two preſidents of that council, four maſter burghers taken from the little council, and the *banneret* or guardian of the liberties of the people. The former ſix are changed every two years; and the banneret is choſen by the general aſſembly of the citizens, and continues in office during ſix years.

When the cauſes are decided in the month of May by the three eſtates, the four judges, who form the third eſtate, retire, and their place is ſupplied by the four miniſtraux. The attorney general then deſires the members of the three eſtates to take into conſideration whether it is neceſſary to frame any new laws. If a new ordinance is propoſed, a declaration is drawn up and delivered to the council of ſtate for their deliberation, whether it be contrary to the prerogatives of the prince or the rights of the ſubject; from thence it is communicated to the council of the town in order to be examined, whether it infringes the privileges of the citizens. If adopted by the council of ſtate and the council of the town, it is propoſed to the prince for his approbation or rejection: in the former caſe it is again publicly read before the three eſtates, and the governor or preſident declares the approbation of the ſovereign. It is then promulgated, or paſſed into a law by the three eſtates. The people of Vallengin have always been conſulted upon the framing a new law ſince the acceſſion of the houſe of Brandenburg. For this purpoſe the three maſter burghers of Vallengin examine, whether it contains any thing inconſiſtent with the franchiſes of that diſtrict; in which caſe they have the power of remonſtrating to the governor in council. Every year, at the concluſion of the aſſembly of the eſtates of Neuchattel, thoſe of Vallengin, as conſtituting the ſupreme court of judicature for that country, meet at Vallengin, and decide finally all appeals from the inferior courts of juſtice. Both principalities are divided into a certain number of diſtricts, each of which has its criminal court of juſtice. Every criminal is brought to trial immediately after he is arreſted, and ſentence is read to him in priſon. Next morning he appears again before the judges, aſſembled in the open air; the former proceedings on the trial are read, and the judges once more deliver their opinion. In capital ſentences the governor is immediately made acquainted with the circumſtances of the caſe; and if he does not mitigate the ſentence, it is put in execution without delay. Torture, though ſeldom uſed, is not entirely aboliſhed in theſe diſtricts. Great circumſpection, however, is made uſe of in judicial proceedings, "which (ſays Mr Coxe) may ſometimes favour the eſcape of the criminal; but the few inſtances of atrocious crimes prove that this humane caution is no encouragement to tranſgreſſions, and is a ſtrong preſumption of the general good morals which prevail among the people. In a word, perſonal liberty is almoſt as tenderly and as ſecurely protected by the laws of this country as by thoſe of our own invaluable conſtitution. Thus the liberties of the people are as well and perhaps better ſecured, than even in the democratical cantons; for although the moſt deſpotic prince in Germany is ſovereign, his power is exceedingly limited. Among the ſtriking circumſtances which characterize this goverment, muſt be mentioned the very liberal encouragment given to ſtrangers who ſettle in the country. They enjoy every privilege of trade and commerce; and in no ſtate are fewer eſſential diſtinctions made between ſtrangers and natives."

NEUFCHATTEAU, a town of France, in Lorrain, and capital of the chatellany of Chatenoi. It is a handſome, populous, trading town; having an abbey of the nuns of St Clair, a commandery of Malta, and ſeveral convents of monks and nuns. It is ſeated in a bottom, in a ſoil fertile in corn, wine, and all the neceſſaries of life, on the river Mouzon. E. Long. 5. 45. Lat. 48. 20.

NEVIS, one of the Caribbee iſlands, lying about ſeven leagues north of Montſerrat, and ſeparated from St Chriſtopher's by a narrow channel. It makes a beautiful appearance from the ſea, being a large conical mountain covered with fine trees, of any eaſy aſcent on every ſide, and entirely cultivated. The circumference is about 21 miles, with a conſiderable tract of level ground all around. The climate in the lower part is reckoned to be warmer than Barbadoes, but it is more temperate towards the ſummit. The ſoil is very fine in the lower part, but grows coarſer as we aſcend. The productions are nearly the ſame with thoſe of St Chriſtopher. There are three pretty good roads or bays, with ſmall towns in their vicinity; Charles Town, Moreton Bay, and Newcaſtle. This pleaſant iſland was ſettled under the auſpices of Sir Thomas Warner from St Chriſtopher's. His ſucceſſor, Governer Lake, was conſidered as the Solon of this little country, in which he diſpoſed of every thing with ſuch prudence, wiſdom, and juſtice, as procured him an high reputation with the French as well as Engliſh. In the Dutch war they met with ſome diſturbance from the French; but by being covered by an Engliſh ſquadron, the enemy were obliged to deſiſt from their intended invaſion, after a ſmart engagement in ſight of the iſland. Sir William Stapleton ſometimes reſided here, and Sir Nathaniel Johnſon conſtantly, at which time the inhabitants of Nevis were computed at 30,000. In the war immediately after the revolution, they exerted themſelves gallantly, and had two regiments of 300 men each. In that of Queen Anne they behaved equally well, though they were leſs fortunate; for the French landing with a ſuperior force, and having inveigled moſt of their ſlaves, they were forced to capitulate. About 4000 of theſe ſlaves the French carried away and ſold to the Spaniards, to work in their mines. The parliament, after making due inquiry into the loſſes they had ſuſtained, voted them about a third part of the ſum in which they had ſuffered. Theſe loſſes by war, an epidemic diſeaſe, and repeated hurricanes, exceedingly diminiſhed the number of the people. They are now thought not to exceed 2000 or 3000 whites, and 6000 blacks. There is here a lieutenant governor, with a council, and an aſſembly, which is compoſed of three members from each of the five pariſhes into which the iſland is divided. The commodities are cotton and ſugar; and about 20 ſail of ſhips are annually employed in this trade.

NEURADA, in botany: A genus of the decagynia order, belonging to the decandria claſs of plants; and in the natural method ranking under the 13th order, *Succulentæ*. The calyx is quinquepartite; there are five petals; the capſule inferior, decemlocular, decaſpermous,

mous, and aculeated. There is only one ſpecies, the *procumbens*. The whole plant is white and woolly: it ſends off numerous ſtalks in every direction, which lie flat on the ground: the leaves ſtand on ſhort footſtalks; they are of an oval ſhape, and plaited like thoſe of the *ladies mantle*. It is a native of the warm climates, and found on dry parched grounds.

NEURITICS, in pharmacy, medicines uſeful in diſorders of the nerves.

NEUROGRAPHY, ſignifies a deſcription of the nerves. See ANATOMY, N° 136.

NEUROPTERA. See ZOOLOGY.

NEUTER, a perſon indifferent, who has eſpouſed neither party, and is neither friend nor foe.

A judge ought to be neuter in the cauſes he judges; in queſtions, where reaſon appears neuter, a man ſhould ever incline to the ſide of the unhappy.

NEUTER, in grammar, denotes a ſort of gender of nouns, which are neither maſculine nor feminine. See GENDER.

The Latins have three kinds of genders, maſculine, feminine, and neuter. In Engliſh, and other modern tongues, there is no ſuch thing as neuter nouns. See NOUN.

Verbs NEUTER, by ſome grammarians called *intranſitive verbs*, are thoſe which govern nothing, and that are neither active nor poſitive. See VERB.

When the action expreſſed by the verb has no object to fall upon, but the verb alone ſupplies the whole idea of the action; the verb is ſaid to be *neuter*: as, I ſleep, thou yawneſt, he ſneezes, we walk, ye run, they ſtand ſtill.

Some divide verbs neuter into, 1. Such as do not ſignify any action, but a quality; as *albet*, "it is white;" or a ſituation, as *ſedet*, "he ſits;" or have ſome relation to place; as *adeſt*, "he is preſent;" or to ſome other ſtate or attribute, as *regnat*, "he rules," &c. And, 2. Thoſe that do ſignify actions, though thoſe ſuch as do not paſs into any ſubject different from the actor; as to dine, to ſup, to play, &c.

But this latter kind ſometimes ceaſe to be *neuter*, and commence active; eſpecially in Greek and Latin, when a ſubject is given them: as, *vivere vitam, ambulare viam, pugnare pugnam*. Thus the old French poets ſay, *Soupirer ſon tourment*; the Engliſh, to *ſigh his woes*, &c.

But this is obſerved only to obtain where ſomething particular is to be expreſſed, not contained, in the verb: as, *vivere vitam beatam*, to live a happy life; *pugnare bonam pugnam*, to fight a good fight, &c.

According to the abbot de Dangeau, *verbs neuter* may be divided into *active* and *paſſive*; the firſt, thoſe that form their tenſes in Engliſh, by the auxiliary verb *to have*; in French, by *avoir*. The ſecond, thoſe that form them in Engliſh with the verb *to be*; in French *étre*.—Thus, to ſleep, to yawn, *dormir* and *eternuer*, are *neuters active*.—To come, and to arrive, are *neuters paſſive*.

NEUTRAL Salts, among chemiſts, thoſe compounded of an acid with any other ſubſtance capable of uniting with it and deſtroying its acidity. Thoſe in which the acid is ſaturated with an earth or a metal are called *imperfect*, but thoſe in which a pure alkali is employed are called *perfect* neutrals.

NEUTRALITY, the ſtate of a perſon or thing that is neuter, or that takes part with neither ſide.

NEW ABBEY, ſituated near Kilcullen bridge, in the county of Kildare, and province of Leinſter, in Ireland. It was founded by Rowland Euſtace, of a great and ancient family in this county; the tower is ſtill ſtanding, and ſome part of the abbey; the ruins of the reſt have contributed to build ſeveral dwellings near it. In the inſide Rowland Euſtace and his lady lie buried; their figures, clothed in armour, are to be ſeen there. Near this is a handſome ſeat of the Carter family, on the oppoſite ſide of the river Liffey.

NEWARK *upon Trent*, in the county of Nottingham, is a great thoroughfare in the York road, 124 miles from London. It has bridges over the Trent, which forms an iſland here, by dividing itſelf into two ſtreams two miles above the town, which meet again two miles below it. A magnificent caſtle was built here in the reign of King Stephen, which held out ſtoutly in the barons wars for King John, who died here, October 19. 1216; and it alſo ſtood out for King Charles I. to the laſt; but after he had put himſelf into the hands of the Scots army then before it. the governor by his order ſurrendered it, after which it was demoliſhed.—It was ſituated near the river; the walls of the towers are very thick, and of a very great height; and were there no hiſtorical teſtimony, theſe remains are ſufficient evidence that it was formerly of great importance. In the court before theſe ruins is a very fine bowling green, and near it a manufactory of ſacking. The town being ſubject to inundations from the river Trent, and often from that circumſtance made impaſſable, a turnpike road, at the inſtigation of a publican, was made about twenty years ago, ſo high as to be paſſed with ſafety in the greateſt floods, by arches of brick being made in ſeveral places to carry off the water, conſtructed by Mr Smeaton, at the expence of 12,000l. Near the town there is a bridge conſtructed for the ſame purpoſe, made moſtly upon dry land, conſiſting of nine arches. It has a neat though ſmall new ſtreet, and a market place that is handſome, though not very ſpacious. Its church, which is reckoned one of the fineſt in the kingdom, was built by Henry VI. and has a lofty ſpire. It was incorporated by King Charles II. with a mayor and 12 aldermen.—The ſame king, in gratitude to the town for its loyalty to his father, gave it the privilege of ſending members to parliament. It has a good trade in corn, cattle, wool, &c. and has a charity ſchool for 36 boys. Its market is on Wedneſday; fairs on the Friday before Paſſion-Sunday, May 14th, Whit-Tueſday, Auguſt 12th, Nov. 1ſt, and Monday before December 11th. Here was an abbey of Auguſtine friars. A free ſchool was founded here, endowed with the lordſhip of Everton in this county; and the vicar of Newark, and the brethren of the Trinity-guild for the time being, who were then the chief governors of this town, were made perpetual truſtees for this foundation. Many Roman urns and other antiquities have been found about this town, from whence it has been ſuppoſed that they had ſome town in the neighbourhood.

NEWBOROUGH, or NEWBURGH, in the Iſle of Angleſey, North Wales, diſtant from London 254 miles, though but a ſmall town, ſituated over againſt Caernarvon in North Wales, about 17 miles ſouthweſt.

weſt from Beaumaris; is governed by a mayor, two bailiffs, and a recorder. Its Welſh name is *Rhôſſir*, or *Rhôſvair*. Its weekly markets, which are pretty well ſupplied with proviſions, are kept on Tueſdays; and its annual fairs on the 22d of June, Aug. 10th and 21ſt, Sept. 25th, and Nov. 11th.

NEWBURG, the name of ſeveral towns of Germany, two of which are the chief towns of duchies of the ſame name; one in Bavaria, and the other in the Palatinate.

NEWBURY, a town in the county of Berks in England, 16 miles from Reading, and 56 from London, aroſe on the decay of Spinham-Land. Notwithſtanding its name ſignifies *New-Borough*, it is as old almoſt as the Conqueſt. It made ſo much broad cloth formerly, that in the reign of Henry VIII. here flouriſhed John Winſcomb, commonly called *Jack of Newbury*, one of the greateſt clothiers that ever was in England, who kept 100 looms in his houſe; and in the expedition to Flowden Field againſt the Scots, marched with 100 of his own men, all armed and clothed at his own expence; and he built all the weſt part of the church. Alſo Mr Kenric, the ſon of a clothier here, though afterwards a merchant in London, left 4000l. to the town, as well as 7500l. to Reading, to encourage the woollen manufactory. It makes a great quantity of ſhalloons and druggets, but not near ſo much broad cloth now as formerly; yet it is a flouriſhing town, with ſpacious ſtreets, and a large market place, in which is the guild-hall. The church is a good one, of ſtone, ſuppoſed to have been built about 1640. It has ſeven ſets of alms houſes. In the neighbourhood, on the banks of the Kennet, there is a ſtratum of petrified wood dug out for firing, when they frequently find trunks of large oaks yet undecayed, with petrified hazel nuts, fir cones, &c. with the bones and horns of ſtags, antelopes, &c. tuſks of boars, and heads of beavers. The river Kennet, which abounds with excellent trout, eels, and cray-fiſh, runs through the town; and here is plenty of all other proviſions. It was made a corporation by Queen Elizabeth, and is governed by a mayor, high ſteward, aldermen, &c. It ſends a great quantity of malt to London, has good inns, and has a charity-ſchool for 40 boys. Its market, which is well ſupplied with corn, is on Thurſdays; and fairs on Holy-Thurſday, July 5th, Aug. 24th, and Oct. 28th.

NEWCASTLE-*Under-Line*, a town in England, in the county of Stafford, on a branch of the Trent, is 15 miles north of Stafford, 33 ſouth ſouth-eaſt of Warrington, and 149 from London; had a caſtle, now in ruins; and is ſo called from an older caſtle, which formerly ſtood two miles off, at Cheſterton-Under-Line. It was incorporated by King Henry I, and again by Queen Elizabath and King Charles II. and is governed by a mayor, two juſtices, two bailiffs, and a common council. The clothing trade flouriſhes here; but its chief manufactory is hats, here being an incorporated company of felt makers. The ſtreets are broad and well paved, but moſt of the buildings low and thatched. The market is on Mondays; fairs Eaſter Monday, Whit-Monday, July 6th, firſt day in September, and November 6th, for cattle. Alſo a great beaſt-market every other Mon- The corporation has a court, which holds pleas for actions under 40l. Its caſtle, of which there is little to be now ſeen, was built in the reign of Henry III. It had four churches formerly, which are now reduced to one, the town having ſuffered much in the barons wars. There are frequent horſe races in the neighbourhood, though it is in a manner ſurrounded with coal pits; particularly one at Hamley-Green. It is ſofter than the cannel coal, and is cut out in ſlices; but conſumes ſo faſt, that it is only fit for forges. There is the greateſt quantity of ſtone ware made near this place of any part of England; ſo that one year with another, they are ſaid to export 20,000l. worth of it.

Newcastle, the capital of the county of Northumberland in England, 14 miles north of Durham, 94 north of York, 63 ſouth by eaſt of Berwick, 60 eaſt of Carliſle, and 271 from London, ſtands at the end of the Picts wall, on the north ſide of the Tyne, over which it has a ſtately bridge into the biſhopric of Durham, in which its ſuburb called *Gateſide* is ſituated; for the liberties of Newcaſtle extend no farther than the great iron gate upon the bridge, which has the arms of the biſhop of Durham carved on the eaſt ſide and thoſe of Newcaſtle on the weſt ſide. It is admitted to have been a Roman ſtation, though no evidence at preſent appears, except at Pandon-gate, whoſe ſuperſtructure is of different workmanſhip and model from any others of the town, the arches being circular. The Carpenter's tower is alſo of Roman original. In the Saxons time it was called *Moncaſter*, from the monks here, who all fled when it was depopulated by the Danes; and afterwards *Newcaſtle*, from a caſtle built here by William the Conqueror's ſon, Robert, in 1080, to defend the country againſt the Scots, whoſe kings had this town before the Norman conqueſt, and ſometimes reſided here.—Several monaſteries and houſes were built here ſoon after the caſtle; and it was greatly enlarged and enriched by a good trade to the coaſts of Germany, and by the ſale of its coal to other parts of England; for which, and for other merchandiſe, it is become the great emporium of the north of England, it being the neateſt and largeſt [illegible] thoſe parts, next to York. In the reign of Edward I. it was burnt by the Scots; but a very rich burgher who was taken priſoner, ſoon ranſomed himſelf for a good ſum of money, and began the firſt fortifications of the place, which he extended from Sand-gate to Pampedon, and thence to the Auſtin friars gate; which the townſmen finiſhed, and encompaſſed with ſtout walls, which extended two miles, wherein are ſeven gates and many turrets, with ſeveral caſements bomb-proof. To which two other gates were added in more modern times, viz. Bridge-gate and Sand-gate: the wall between them was afterwards removed to open the quay. Edward III. granted the corporation the duties and cuſtoms of the town for ſeven years, to enable them to complete the fortification. It is a borough at leaſt as ancient as King Richard II. who granted that a ſword ſhould be carried before the mayor; and King Henry VI. made it a town and county incorporate of itſelf, independent of Northumberland. Henry VII. built a monaſtery here for the Franciſcans. Beſides which, it had ſeveral religious foundations, ſeveral of which ſtructures have been converted to companies halls and private reſidences. In the reign of Henry VIII. this place is ſaid to have exceeded in the ſtrength and magnificence of its works all the cities of England, and moſt places in Europe. The town is governed by a mayor, 12 aldermen, a recorder, ſheriff, town clerk, a clerk of the chambers, two coroners, eight chamberlains, a ſword bearer, a water bailiff, and ſeven ſerjeants at mace. Its ſituation, eſpecially the moſt buſy part of it towards the river, is very uneven, it being built on the declivity of a ſteep hill, and the houſes very cloſe. The caſtle overlooks the whole town. That part built by Robert was of great ſtrength, and ſquare, and ſurrounded by two walls; the ſquare was 62 feet by 54, and the walls 13 feet thick, within which was a chapel. The outward fortifications are now defaced, and their ſite crowded with buildings. The tower remains entire, and ſituated on a lofty eminence, and its principal entrance is to the ſouth. This caſtle belongs to the county, and makes no part of the liberties.—It is now the county priſon, and in the great hall the judges hold the aſſizes. Here Baliol king of Scotland did homage to King Edward I. in 1292; as did Edward Baliol in 1334 to King Edward III. Here is a magnificent exchange and a cuſtomhouſe; and the fineſt quay in England, except that at Yarmouth, being 700 yards long, it being far more ſpacious and longer than thoſe at London or Briſtol, though not equal to either for buſineſs. There is a handſome manſion houſe for the mayor, who is allowed 1000l. a-year for his table, beſides a coach and barge. The old bridge was carried away in a flood, and the preſent was erected about 1775, of nine noble elliptic arches. With the old bridge 22 houſes were thrown down, and ſix lives loſt. It was originally built of wood; but having been deſtroyed by fire in 1248, was rebuilt of ſtone, and conſiſted of 12 arches, three of which on the north ſide were cloſed up, and ſerved for cellars; this was again rebuilt about 1450, and was crowded with wooden buildings; but near the middle was a tower with an iron gate, uſed as a town priſon. A ſtrong building croſſed the bridge, which was uſed as a magazine. On the ſouth front was a ſtatue of King Charles II. [illegible]er which deſtroyed this bridge, on November 11. 1771, was upwards of 12 feet above high water mark in ſpring tides.—On deſtroying the ruinated piers of the old bridge to erect the preſent, by obſervations made, and medals found, part of it is ſuppoſed to have exiſted from the time of the Romans. It is computed that above 6000 keelmen are employed here, who have formed themſelves into a friendly ſociety; and, by their own contributions, built a noble hoſpital containing 50 chambers, for ſuch of their fraternity as are poor, diſabled, or paſt their labour; and it is ſupported by the contribution of thoſe that are in health. The town is extremely populous; and, notwithſtanding the multitude of thoſe employed in and about the coal pits, with which the town is in a manner ſurrounded, has abundance of poor; but it has alſo many wealthy inhabitants, and it is ſaid they pay above 4000l. a-year to their relief. It is obſerved, that this town has the greateſt public revenue in its own right as a corporation, of any town in England, it being computed at no leſs than 8000l. a-year. In 1774, the receipts of the corporation were 20,360l. 9s. 8d.; and their diſburſements about 19,445l. The number of inhabitants far exceeds 30,000. Here are four churches or chapels. That of St Nicholas is the mother church, a curious fabric, built cathedral-wiſe by David king of Scots, 240 feet long, 75 broad, and proportionably high, with a tower ſteeple 194 feet in height, of Gothic architecture; alſo St Andrew's, St John's, and All Saints, lately rebuilt on the ſite of the old ſtructure, of a circular form. Here are alſo ſeveral meeting houſes, and four charity ſchools for 300 children; a fine hall for the ſurgeons, and a large priſon called *Newgate;* alſo an hoſpital for lunatics, another for the lying-in of married women, as well as a fund raiſed for the relief of thoſe who are delivered at their own houſes. Here is a well endowed and large infirmary, and an aſſembly room that attracts attention, containing every uſeful apartment, and a ball-room 93 feet by 40: The front is ornamented with ſix Ionic pillars, &c. In another part of the town is a new theatre. Here is a very neat ſet of baths. A free grammar ſchool was granted by James I. from an old foundation of St Mary's hoſpital, in the veſtry room of whoſe chapel is the election of the officers of the corporation. There were formerly ſeveral palaces in this city, viz. Pampedon hall, Lumley place, Earl's place, Northumberland houſe, Weſtmoreland place, &c. The free maſons have lately erected an elegant hall, richly ornamented, to hold their lodge in, near High friar chair, capable of holding above 4000 of that ancient fraternity. Here is an hoſpital for 39 decayed freemen and their widows; and another for three clergymen's widows and three merchants widows. The Maiden's hoſpital, built in 1753, is endowed with 2400l. for ſix maiden women and ſix poor men. Dr Thomlin, a prebendary of St Paul's, and rector of Whicham in the biſhopric of Durham, lately gave a library of above 6000 valuable books to the corporation, and ſettled a rent charge of 5l. a-year for ever for buying new ones; and Walter Blacket, Eſq; one of its repreſentatives in parliament, built a neat repoſitory for them, and ſettled 25l. a-year for ever on a librarian. The upper or north part of the town, inhabited by the politer ſort of people, is much pleaſanter than that part next the river, and has three level, well built, and ſpacious ſtreets. The river all the way up from Shields to Newcaſtle is broad, the channel ſafe, and the tide flows with a ſtrong current to the town, and far beyond it. In the beginning of the late civil wars, this town was taken and plundered by the *Scotch fanatics*, who here ſold their king, Charles I. for 200,000l. in hand, and ſecurity for as much more. The glaſs works are very curious, and have more buſineſs of the fine ſort than moſt other places. Beſides, it has a conſiderable manufacture of broad and narrow cloths, and ſeveral ſoap boileries; and this place is famous for grindſtones, for which there is ſuch a demand, that ſcarce a ſhip ſtirs without them; from whence came the proverb, "That a Scotſman and a Newcaſtle grindſtone travel all the world over." Ships fit for the coal trade are built here to perfection, with great ſtrength. Here is a conſiderable manufactory of hardware and wrought iron, after the manner of that at Sheffield.—Its markets are on Tueſdays and Saturdays. Its fairs in Auguſt, which laſt nine days, and October 29th, which laſt nine days. By an act of Queen Mary, the price of the carriage of goods hither from London by waggons was ſettled at 2d. per lb. London alone is ſaid to conſume at leaſt 766,887 chaldrons of its coal every year: but as for the fiſh vended in that city by the name of *Newcaſtle ſalmon*, it is more properly called *Berwick ſalmon*, the freſh ſalmon being taken near 50 miles farther, as far as the Tweed, and brought on the backs of horſes to Shields, where it is cured, pickled, and ſent on board for London. It is worth remembering, that at the aſſizes here in 1743, two old men were ſubpœna'd hither as witneſſes from a neighbouring village, viz. one 135 years of age, and his ſon 95, both hearty, and having their ſight and hearing; and that in 1744, one Adam Turnbull died in this town aged 112, who had had four wives, the laſt of whom he had married when he was near 100 years old.

The annual amount of the revenue of cuſtoms at this port, which Mr Brand in his Hiſtory of Newcaſtle ſtates at 41,000l. is now very conſiderably upwards of 70,000l.

The coals carried out of it annually (on an average from 1785 to 1791) were nearly 448,000 Newcaſtle chaldrons; the weight of which is 1,187,200 tons.

The manufacture of earthen ware is greatly increaſed, and carried on to great perfection in its neighbourhood, in ſeven potteries; and their produce exported hence to foreign parts, as well as to the different ports of this kingdom; ſome of which potteries conſtantly employ upwards of 100 perſons, men, women, and children.

New works of conſiderable extent for the manufacture of iron have been eſtabliſhed; as alſo a very capital manufactory for white lead, milled lead, &c.

The trade with the Weſt India iſlands is increaſing, and may in time become very conſiderable; as the port has great advantages, in being able to ſupply on the cheapeſt terms many articles wanted in thoſe iſlands; ſuch as coals, grindſtones, lime, bricks, tiles, iron wares, &c.; and is moſt advantageouſly ſituated for the re-exportation of the Weſt India produce to the ports on the Baltic, to Germany, the United Provinces, Flanders, and part of France; and moreover, the riſk of navigation, and the rate of inſurance, not being greater than between thoſe iſlands and Liverpool, and ſome other ports on the weſtern coaſt of this kingdom.

The town of Newcaſtle is daily increaſing in its population and opulence; and it would be well if it could not be added, in luxury, the almoſt neceſſary conſequence of riches: but it ſhould not be omitted, that it is noted for hoſpitality and good living.

Great improvements have been made in the town, by opening new ſtreets, and paving the principal ones, in the ſame manner as in London. It cannot be ſaid that it is well lighted, the few lamps ſcattered here and there ſerving but to make darkneſs viſible; nor have the orders repeatedly given by the magiſtrates for cleaning the ſtreets been attended with the full deſired effect.

To the liſt of public edifices of modern erection, and mentioned above, viz. the grand aſſembly rooms, and the elegant theatre, which were built by ſubſcription, and the ſuperb pariſh church of All Saints, built at a very great expence by the pariſhioners, may be added a commodious riding houſe, built alſo by ſubſcription.

Newcastle, a borough town of Ireland, in the county of Dublin, and province of Leinſter, which returns two members to parliament, and holds two fairs, 9th of May and 8th of October.

Newcastle is alſo the name of a handſome town in the county of Limerick and province of Munſter, on the high road to Kerry, 114 miles from Dublin. Here was a religious houſe poſſeſſed by the knights templars. It is ſaid, they uſed ſome barbarous cuſtoms which greatly diſguſted the Iriſh, who, watching a favourable opportunity, attacked a number of the knights riding out together and put them to death; the place is ſtill remembered where their remains were interred. This order was ſuppreſſed in the famous council of Vienna, 22d of March 1312. Newcaſtle conſiſts of a large ſquare where markets and fairs are held; on the northern ſide ſtands a market houſe, with an aſſembly room; on the ſouth ſide is the church, which is the neateſt in the county, and it was finiſhed in 1777 at the ſole expence of Lord Courtenay. It ſtands cloſe to the walls and fortifications of the knights templars, of which one of the caſtles is fitted up for Lord Courtenay's agent.

Newcastle, a ſmall town in America, 35 miles below Philadelphia, on the weſt bank of Delaware river. It was firſt ſettled by the Swedes about the year 1627, and called *Stockholm*. It was afterwards taken by the Dutch, and called *New Amſterdam*. When it fell into the hands of the Engliſh, it was called by its preſent name. It contains about 60 houſes, which have the aſpect of decay, and was formerly the ſeat of government. This is the firſt town that was ſettled on Delaware river.

Newcastle (Duke of). See **Cavendish**.

New England. See *England* (*New*.)

New Foreſt of Hampſhire in England, is a tract of at leaſt 40 miles in compaſs, which had many populous towns and villages, and 36 mother churches, till it was deſtroyed and turned into a foreſt by William the Conqueror. There are nine walks in it; and to every one a keeper, under a lord warden, beſides two rangers, and a bow-bearer. As this large tract lay many ages open and expoſed to invaſions from foreigners, King Henry VIII. built ſome caſtles in it; and it has now ſeveral pretty towns and villages. It is ſituated in that part of Hampſhire which is bounded on the eaſt by Southampton river, and on the ſouth by the Britiſh Channel. It poſſeſſes advantages of ſituation, with reſpect to the convenience of water carriage and nearneſs to the dock yards, ſuperior to every other foreſt, having in its neighbourhood ſeveral ports and places of ſhelter for ſhipping timber, among which Lymington is at the diſtance of only two miles, Bewley about half a mile, and Redbridge three or four miles from the foreſt; and the navigation to Portſmouth, the moſt conſiderable dock yard in this kingdom, is only about 30 miles from the neareſt of thoſe places. This is the only foreſt belonging to the crown of which the origin is known. Doomſday-book contains the moſt diſtinct account of its afforeſtation by William the Conqueror: the contents of every

every field, farm, or eſtate afforeſted, in hides, carucates, or virgates, by which the extent of land was then computed, together with the names of the hundreds and villages, and of the former proprietors (which are for the moſt part Saxon), the rent or yearly value of each poſſeſſion, and the tax which had been paid for it to the crown during the reign of Edward the Confeſſor, before the inhabitants were expelled, and that part of the country laid waſte, are all to be found in that moſt curious and venerable record. Wiſhing to diſcover the original extent of the foreſt, we extracted, for our own information, all that relates to it in that ancient ſurvey. The extract is far too voluminous for inſertion. The names of many of the places having been changed ſince that time, it is difficult to aſcertain with preciſion what were then the limits of the foreſt. The oldeſt perambulation we have met with is among the Pleas of the Foreſt, in the eighth year of King Edward I. preſerved in the Chapter-houſe at Weſtminſter. The boundaries there deſcribed include all the country from Southampton river on the eaſt to the Avon on the weſt, following the ſea coaſt as far as the ſouthern boundary between thoſe rivers, and extending northwards as far as North Chadeford, or North Charford, on the weſt, and to Wade and Orebrugg, or Owerbridge, on the eaſt; and the greateſt part, if not the whole, of that extenſive diſtrict, is mentioned in Doomſday book to be the foreſt belonging to the crown. Another perambulation was however made in the 29th of the ſame king, which leaves out a great part of the country contained within the former. This perambulation, which is preſerved in the tower of London, confines the foreſt to limits which, as far as we can trace them, appear to have been followed in the 22d year of Charles II. when the foreſt was again perambulated. By the *Charta de Foreſta*, all lands not belonging to the crown which had been afforeſted by Henry II. Richard I. or King John, were to be diſafforeſted; but as no proviſion was made for the reduction of the more ancient afforeſtations, it is eaſy to account for the great diminution of this foreſt in the reign of Edward I. who was not a prince likely to ſubmit to any encroachment on his rights. The perambulation of the 22d of Charles II. is the laſt which we find on record: it contains the preſent legal bounds of the foreſt, and was given to the ſurveyors as their guide, in taking the plan which they have made lately by direction. From that plan, with the approbation of the lords commiſſioners of his majeſty's treaſury, an engraving was made. According to the laſt-mentioned perambulation and the plan, the foreſt extends from Godſhill on the north-weſt to the ſea on the ſouth-eaſt, about 20 miles; and from Hardley on the eaſt to Ringwood on the weſt, about 15 miles; and contains within thoſe limits about 92,365 acres ſtatute meaſure. The whole of that quantity, however, is not foreſt land, or now the property of the crown: there are ſeveral manors and other conſiderable freehold eſtates within the perambulation, belonging to individuals, to the amount of about 24,797 acres; about 625 acres are copyhold or cuſtomary lands belonging to his majeſty's manor of Lyndhurſt; about 1004 acres are leaſe-hold under the crown, granted for certain terms of years, and forming part of the demiſed land revenue, under the management of the ſurveyor-general of crown lands; about 901 acres are purpreſtures or encroachments on the foreſt; about 1193 acres more are encloſed lands held by the maſter-keepers and groom-keepers, with their reſpective lodges; and the remainder, being about 63,845 acres, are woods and waſte lands of the foreſt. To perpetuate the ſpot where William Rufus was killed by the glance of an arrow ſhot at a ſtag, a triangular ſtone was erected in 1745. George III. viſited this ſpot in 1789. In Auguſt 1782, a curious ancient golden croſs was found here by a labouring man digging turf. It weighed above an ounce of gold, and had on one ſide an engraving of our Saviour, and on the other, the ladder, ſpear, nails, and other emblems of his ſufferings.

New Years Gifts. Preſents made on the firſt day of the new year. Nonius Marcellus refers the origin of this cuſtom among the Romans to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who having conſidered as a good omen a preſent of ſome branches cut in a wood conſecrated to *Strenia*, the goddeſs of ſtrength, which he received on the firſt day of the new year, authorized this cuſtom afterwards, and gave to theſe preſents the name of *ſtrena*. However this may be, the Romans on that day celebrated a feſtival in honour of Janus, and paid their reſpects at the ſame time to Juno; but they did not paſs it in idleneſs, leſt they ſhould become indolent during the reſt of the year. They ſent preſents to one another of figs, dates, honey, &c. to ſhow their friends that they wiſhed for a happy and agreeable life. Clients, that is to ſay, thoſe who were under the protection of the great, carried preſents of this kind to their patrons, adding to them a ſmall piece of ſilver. Under Auguſtus, the ſenate, the knights, and the people, preſented ſuch gifts to him, and in his abſence depoſited them in the capitol. Of the ſucceeding princes ſome adopted this cuſtom and others aboliſhed it; but it always continued among the people. The early Chriſtians condemned it, becauſe it appeared to be a relick of Paganiſm and a ſpecies of ſuperſtition; but when it began to have no other object than that of being a mark of veneration and eſteem, the church ceaſed to diſapprove of it.

NEWEL, in architecture, is the upright poſt which a pair of winding ſtairs turn about; this is properly a cylinder of ſtone, which bears on the ground, and is formed by the end of the ſteps of the winding ſtairs.

NEWFIDLER-SEA, a lake in Hungary, 17 miles in length and 6 in breadth.

NEWFOUNDLAND, a large iſland of North America, belonging to Great Britain, lying between 46. 50. and 51. 30. N. Lat. and between 53. 30. and 58. 20. W. Long. from London. The form is that of an irregular triangle, the baſe or ſouth ſide being 80 leagues in extent; the eaſt ſide is the longeſt; and the whole circumference about 150 leagues. It is bounded on the north by the ſtraits of Belleiſle, which ſeparate it from Labrador; on the eaſt and

Newfoundland.

Newfoundland.

ſouth it hath the Atlantic ocean, and on the weſt the gulf of St Lawrence. The climate is rather ſevere; and the ſoil, at leaſt on the ſea coaſt, which is all that we know of it, is poor and barren. A few kitchen vegetables with ſtrawberries and raſpberries are all its produce. The country within land is mountainous, and abounds with timber; there are ſeveral rivers which are plentifully ſtored with various ſorts of fiſh, abundance of deep bays, and many good ports. St John's and Placentia are the two principal ſettlements, and at each of theſe there is a fort; the number of people who remain here in the winter hath been computed at 4000. The French, by the treaty of Utrecht, were permitted to fiſh from Cape Bonaviſta on the eaſt ſide round the north of the iſland to Point Rich on the weſt; and by the treaty of Paris, they are allowed the iſles of St Pierre and Miquelon, upon which they are to dry their fiſh, but not to erect fortifications of any kind.

The great importance of this place ariſes from its fiſhery, which is in part carried on by the inhabitants at the ſeveral harbours, which are about 20 in number, who take vaſt quantities of cod near the coaſt, which they bring in and cure at their leiſure, in order to have it ready for the ſhips when they arrive. But the great and extenſive fiſhery is on the banks at ſome diſtance from the iſland. The great bank lies 20 leagues from the neareſt point of land from the latitude 41° to 49°, ſtretching 300 miles in length and 75 in breadth.—To the eaſt of this lies the Falſe Bank; the next is ſtyled *Vert* or *the Green Bank*, about 240 miles long, and 120 over; then Banquero, about the ſame ſize; the ſhoals of Sand Iſland, Whale Bank, and the Bank of St Peter's, with ſeveral others of leſs note, all abounding with fiſh.

The cod are caught only by a hook; and an expert fiſher will take from 150 to 300 and upwards in a day; for the fiſh never bite in the night, and the labour is very great. The ſeaſon is from May to October, in the height of which there are from 500 to 700 ſail upon the banks at a time. The fiſh caught in the ſpring months are beſt; they are cured in very different ways. Some are ſtyled *white fiſh*, others *mud fiſh*, which are ſtowed and ſalted in the hold, and will not keep long; but the beſt and moſt valuable are the dried cod. The quantity taken is prodigious: yet in ſome ſeaſons and in different places varies conſiderably, as the fiſh frequently change their ſtations. The *fiſhing ſhips*, as they are called, lie upon the banks, with the help of their boats take and cure their own fiſh, and as ſoon as they are full ſail for a market. The ſack ſhips proceed directly to the iſland, where they purchaſe fiſh from the inhabitants either by barter or bills of exchange. The principal markets for cod are Spain, Portugal, Italy, and the Weſt Indies. The value of this fiſhery is computed at ſome hundred thouſand pounds annually; employing, beſides ſeveral hundred ſhips, ſome thouſands of ſeamen, and affording a maintenance to a number of tradeſmen of different occupations, by which many large towns on the weſt ſide of England accumulate much wealth, and at the ſame time contribute in many reſpects to the benefit of the public.

The great utility of this fiſhery was very early ſeen, and very vigorouſly purſued; for in the beginning of the reign of King James I. we had two hundred and fifty ſail employed therein. It is computed, that three quintals of wet fiſh make one quintal of dried cod. Beſides, the livers of every hundred quintals make a hogſhead of oil; and excluſive of theſe there are many leſſer advantages that go in diminution of the expence. The fiſhery, as we have ſaid above, produces differently in different ſeaſons; but it is judged to be a very good one when it produces 300,000 quintals of fiſh and 3000 barrels of oil, both equally ſaleable and valuable commodities. As every ſhip carries twelve, and each of their boats eight men, and as theſe return home in ſix months there cannot be a more noble nurſery for ſeamen. The artificers and traders employed in building, victualling, and repairing theſe veſſels, are very numerous in the reſpective ports from which they ſail. Theſe circumſtances juſtify the particular attention paid by government to this branch of the public ſervice; in reſpect to which that they may be well informed, an annual and very diſtinct account, by which the whole is ſeen at one view, is delivered by the proper officer to the governor of Newfoundland, that is, to the commodore of his majeſty's ſquadron. Mr Pennant, in the appendix to his Arctic Zoology, gives us, from what appears to be very good authority, the following account of this iſland.

" Within the circuit of 60 miles of the ſouthern part, the country is hilly, but not mountainous. The hills increaſe in height as they recede from the ſea; their courſe is irregular, not forming a chain of hills, but riſing and falling abruptly. The coaſts are high, and the ſhores moſt remarkably bold. The ſame may be ſaid of almoſt every part of this vaſt iſland. The country is much wooded, and the hills (ſuch as have not flat tops to admit the rain to ſtagnate on them) are clothed with birch, with hazel, ſpruce, fir, and pine, all ſmall; which is chiefly owing to the inhabitants taking off the bark to cover the fiſh ſtages. This peninſula is ſo indented by the fine and deep bays of Placentia, St Mary, Conception, and Trinity, that it may be eaſily penetrated in all parts, which is done for the ſake of fowling, or the procuring of ſpars for maſts, oars, &c. The iſland is on all ſides more or leſs pierced with deep bays, which peninſulate it in many places by iſthmuſes moſt remarkably narrow.—The mountains on the ſouth-weſt ſide, near the ſea, are very high, and terminate in lofty headlands; ſuch are Chapeau Rouge, a moſt remarkably high promontory, Cape St Mary's, and Cape le Hune. Such in general is the formation of the iſland; on the north-eaſt, moſt of the hills in the interior part of the country terminate pyramidally, but form no chain. The interior parts of the country conſiſt chiefly of moraſſes, or dry barren hammocks, or level land, with frequent lakes or ponds, and in ſome places covered with ſtunted black ſpruce. The rivers of Newfoundland are unfit for navigation, but they are of uſe in floating down the wood with the ſummer floods. Still the rivers and the brooks are excellent guides for the hunters of beavers and other animals, to penetrate up the country, which as yet has never been done deeper than 30 miles. Near the brooks it is that timber is commonly met with, but ſeldom above three or four miles inland, and in valleys; the hills in the northern diſtrict being naked and barren.

" In ſome parts of Newfoundland there is timber ſufficiently large for the building of merchant ſhips: the hulk is made of juniper, and the pine furniſhes maſts and yards; but as yet none has been found large enough for a maſt for a large cutter. The fiſhery is divided into two ſeaſons; that on the ſhore, or the ſhore ſeaſon, commences about the 20th of April, and ends about the 10th of October; the boats fiſh in from four to 20 fathoms of water. The moſt important, the bank fiſhing ſeaſon, begins the 10th of May, and continues till the laſt of September, and is carried on in 30 to 45 fathoms depth of water. Banking veſſels have ſailed from St John's to the bank as early as the 12th of April. At firſt they uſe pork or birds for a bait; but as they catch fiſh, they ſupply themſelves with a ſhell fiſh called clams, which is found in the belly of the cod. The next bait is the lobſter; after that the herring and the launce, which laſt till June, when the capelan comes on the coaſt, and is another bait. In Auguſt the ſquid comes into uſe, and finally the herring again. The greateſt number of cod fiſh taken by a ſingle fiſherman in the ſeaſon has been 12,000, but the average is 7000. The largeſt fiſh which has been taken was four feet three inches long, and weighed 46 pounds. A banking veſſel of 10,000 fiſh ought to be filled in three weeks, and ſo in proportion; and 80 quintals (112 lb. each) for a boat in the ſame time.

"In 1785, 541 Engliſh veſſels fiſhed on the bank, a number exceeding that of the French. A heap of dried fiſh, 20 feet long and ten wide, and four deep, contains 900 quintals. Such a heap ſettles, in the courſe of 48 hours after it is made, about $\frac{1}{11}$. An extraordinary ſplitter will ſplit five quintals of fiſh in an hour. The average in that time is two. There is no fiſhing during winter, on account of the inclemency of the ſeaſon. It is ſuppoſed that the fiſh in a great meaſure quit the banks before that time, as in general they are very ſcarce when the fiſhing veſſels go upon the banks early in the ſpring.

"There are a few ſmall towns on the coaſts, which have gardens ſown with Engliſh pulſe; but many of the inhabitants quit the country in winter.

"An admiral or ſome ſea officer is governor of Newfoundland. He ſails from England in May, and returns by the 30th of November."

NEWMARKET, in Cambridgeſhire, 13 miles from Cambridge, 13 from St Edmundſbury, and 60 from London, is a town with one long ſtreet, the north ſide in Suffolk, the ſouth ſide in Cambridgeſhire. It is a healthy place, and a great thoroughfare in the road from London to Norfolk; but ſtands moſtly by the horſe races every year in April and October, here being the fineſt courſe in England; on which there is a houſe for the king when he comes to the races, which was built by Charles II. The king gives a plate or two every year, beſides thoſe given by the nobility; and wagers are laid upon the horſes, which are ſeldom under 500l. and often above 1000l. Here are two coffeehouſes, at which, every night and morning during the races, there is gaming, as there is alſo at the houſes of the nobility and gentry. Here are alſo cock matches. Here is a little chapel, which is a chapel of eaſe to the mother church at Ditton; and another in the Suffolk ſide, which is parochial. The town was burnt in 1683, but ſoon rebuilt. Here are two charity ſchools, one for 20 boy another for 20 girls, ſupported by 50l. a-year, firſt ſettled by Queen Anne. Here is a market on Tueſdays and Thurſdays, and fairs on October 28. and Whitſun-Tueſday.

NEWROSS, a borough town in the county of Wexford, and province of Leinſter, in Ireland, 67 miles from Dublin. It returns two members to parliament; the patronage is in the families of Tottenham and Leigh. This town was formerly walled, and ſome of the gates ſtill remain. It lies on the river Barrow, which is here very deep, and ſhips of burden can come up to the quay even when the tide is out. The church is large, but the cuſtomhouſe and quay are both ſmall, and ſometimes overflooded many feet. It is one of the ſtaple ports for exporting wool, yet its trade is but inconſiderable; beef and butter are the principal articles exported. Here is a barrack for a troop of horſe, and a good ferry into the county of Kilkenny. Near this town is a charter ſchool. It is alſo a poſt town, and gives title of earl to the family of Gore. It was formerly fortified, and adorned with many religious houſes, among which was a crouched friary, built on the ſummit of a hill in the town; but one of the friars having killed a principal inhabitant, the whole body of the people aroſe, put the friars to death, and totally deſtroyed the friary; on the ſite of which the monaſtery of St Saviour, for conventual Franciſcans, was afterwards erected by Sir John Devereux; and the eaſt end of this laſt building is now the pariſh church. A friary for Eremites, following the rule of St Auguſtine, was alſo founded here in the reign of Edward III.

NEWSPAPERS, periodical publications, daily, weekly, &c. for the purpoſe of communicating to the world every thing of importance, whether political or literary, &c. which is going on. They have tended much to the diſſemination of learning, and have ſerved many other valuable purpoſes; and while they are carried on with candour, impartiality, and ability, they are unqueſtionably a great national benefit. W this, however, is not the caſe, and it often happens, they diſgrace their authors, and are highly injurious to the public. They were firſt publiſhed in England, Auguſt 22. 1642. *Journal des Sçavans*, a French paper, was firſt publiſhed in 1665, though one was printed in England, under the title of the *Public Intelligencer*, by Sir Roger L'Eſtrange, 1663, which he dropped, on the publication of the firſt London Gazette. Newſpapers and pamphlets were prohibited by royal proclamation 1680. Though at the Revolution prohibitions of this kind were done away, and the preſs ſet at liberty, yet newſpapers were afterwards made objects of taxation, and for this purpoſe were firſt ſtamped 1713. The number of them, however, gradually increaſed; and there were printed in the whole kingdom during the years 1775, 12,680,000; 1776, 12,830,000; 1777, 13,150,642; 1778, 13,240,059; 1779, 14,106,842 1780, 14,217,371; 1781, 14,397,620; 1782, 15,272,519. They are now ſtill more numerous.

NEW Style, firſt uſed in England in 1753, was introduced into the weſtern world by Pope Gregory XIII. See Chronology, N° 24.

NEWT, or EFT, in zoology, the common lizard. See LACERTA.

NEWTON (Sir Iſaac), one of the greateſt philoſophers and mathematicians the world has ever produced, was the only child of Mr John Newton of Colesworth, not far from Grantham in Lincolnſhire, who had an eſtate of about 120l. *per annum*, which he kept in his own hands. He was born at that place on Chriſtmas day 1642. His father dying when he was young, his mother's brother, a clergyman of the name of *Ayſcough*, or *Aſkew*, who lived near her, and directed all her affairs after the death of Mr Newton, put her ſon to ſchool at Grantham. When he had finiſhed his ſchool learning, his mother took him home, intending, as ſhe had no other child, to have the pleaſure of his company; and that he, as his father had done, ſhould occupy his own eſtate. But his uncle happening to find him in a hay loft at Grantham working a mathematical problem, and having otherwiſe obſerved the boy's mind to be uncommonly bent upon learning, he prevailed upon her to part with him; and ſhe ſent him to Trinity College in Cambridge, where her brother, having himſelf been a member of it, had ſtill many friends. Iſaac was ſoon taken notice of by Dr Iſaac Barrow; who, obſerving his bright genius, contracted a great friendſhip for him. M. de Fontenelle tells us, "That in learning mathematics he did not ſtudy Euclid, who ſeemed to him too plain and ſimple, and unworthy of taking up his time. He underſtood him almoſt before he read him; and a caſt of his eye upon the contents of his theorems was ſufficient to make him maſter of them. He advanced at once to the geometry of Des Cartes, Kepler's Optics, &c. It is certain that he had made his great diſcoveries in geometry, and laid the foundation of his two famous works the *Principia* and the *Optics*, by the time he was 24 years of age."

In 1664, he took the degree of bachelor of arts; and in 1668 that of maſter, being elected the year before, fellow of his college. He had before this time diſcovered the method of fluxions; and in 1669 he was choſen profeſſor of mathematics in the univerſity of Cambridge, upon the reſignation of Dr Barrow. The ſame year, and the two following, he read a courſe of optical lectures in Latin, in the public ſchools of the univerſity; an Engliſh tranſlation of which was printed at London in 1728, in 8vo, as was the Latin original the next year in 4to. From the year 1671 to 1679, he held a correſpondence by letters with Mr Henry Oldenburg ſecretary of the Royal Society, and Mr John Collins fellow of that ſociety; which letters contain a variety of curious obſervations.

Concerning the origin of his diſcoveries, we are told, that as he ſat alone in a garden, the falling of ſome apples from a tree led him into a ſpeculation on the power of gravity; that as this power is not diminiſhed at the remoteſt diſtance from the centre of the earth to which we can riſe, it appeared to him reaſonable to conclude, that it muſt extend much farther than was uſually thought; and purſuing this ſpeculation, by comparing the periods of the ſeveral planets with their diſtances from the ſun, he found, that if any power like gravity held them in their courſes, its ſtrength muſt decreaſe in the duplicate proportion of the increaſe of diſtance. This inquiry was dropped; but reſumed again, and gave riſe to his writing the treatiſe which he publiſhed in 1687, under the name of *Mathematical Principles of Natural Philoſophy*; a work looked upon as the production of a celeſtial intelligence rather than of a man. The very ſame year in which this great work was publiſhed, the univerſity of Cambridge was attacked by King James II. when Mr Newton was one of its moſt zealous defenders, and was accordingly nominated one of the delegates of that univerſity to the high-commiſſion court; and the next year he was choſen one of their members for the convention parliament, in which he ſat till it was diſſolved. In 1696, Mr Montague, then chancellor of the exchequer, and afterwards earl of Halifax, obtained for him of the king the office of warden of the mint; in which employment he was of ſignal ſervice, when the money was called in to be recoined. Three years after, he was appointed maſter of the mint; a place of very conſiderable profit, which he held till his death. In 1699, he was elected one of the members of the Royal Academy of Sciences at Paris. In 1701, he was a ſecond time choſen member of parliament for the univerſity of Cambridge. In 1704, he publiſhed his *Optics*; which is a piece of philoſophy ſo new, that the ſcience may be conſidered as entirely indebted to our author. In 1705, he was knighted by Queen Anne. In 1707, he publiſhed his *Arithmetica Univerſalis*. In 1711, his *Analyſis per Quantitatum Series, Fluxiones et Differentias*, &c. was publiſhed by William Jones, Eſq. In 1712, ſeveral letters of his were publiſhed in the *Commercium Epiſtolicum*. In the reign of George I. he was better known at court than before. The princeſs of Wales, afterwards queen conſort of England, uſed frequently to propoſe queſtions to him, and to declare that ſhe thought herſelf happy to live at the ſame time with him, and have the pleaſure and advantages of his converſation. He had written a treatiſe of ancient chronology, which he did not think of publiſhing; but the princeſs deſired an abſtract, which ſhe would never part with. However, a copy of it ſtole abroad, and was carried into France; where it was tranſlated and printed, with ſome obſervations, which were afterwards anſwered by Sir Iſaac. But, in 1728, the Chronology itſelf was publiſhed at London in quarto; and was attacked by ſeveral perſons, and as zealouſly defended by Sir Iſaac's friends. The main deſign of it was to find out, from ſome tracts of the moſt ancient Greek aſtronomy, what was the poſition of the colures with reſpect to the fixed ſtars, in the time of Chiron the centaur. As it is now known that theſe ſtars have a motion in longitude of one degree in 72 years, if it is once known through what fixed ſtars the colure paſſed in Chiron's time, by taking the diſtance of theſe ſtars from thoſe through which it now paſſes, we might determine what number of years is elapſed ſince Chiron's time. As Chiron was one of the Argonauts, this would fix the time of that famous expedition, and conſequently that of the Trojan war; the two great events upon which all the ancient chronology depends. Sir Iſaac places them 500 years nearer the birth of Chriſt than other chronologers generally do.

This great man had all along enjoyed a ſettled and equal ſtate of health to the age of 80, when he began to be afflicted with an incontinence of urine. However, for the five following years, he had great intervals of eaſe, which he procured by the obſervance of a ſtrict regimen. It was then believed that he certainly had the ſtone; and when the paroxyſms were ſo violent, that large drops of ſweat ran down his face, he never uttered the leaſt complaint, or expreſſed the ſmalleſt degree of impatience; but, as ſoon as he had a moment's eaſe, would ſmile and talk with his uſual cheerfulneſs. Till then he always read and wrote ſeveral hours in a day. He had the perfect uſe of all his ſenſes and underſtanding till the day before he died, which was on the 20th of March 1726-7 in the 85th year of his age. He lay in ſtate in the Jeruſalem chamber at Weſtminiſter, and on the 28th of March his body was conveyed into Weſtminſter abbey; the pall being ſupported by the lord chancellor, the dukes of Montroſe and Roxburgh, and the earls of Pembroke, Suſſex, and Macclesfield. The biſhop of Rocheſter read the funeral office, being attended by all the clergy of the church. The corpſe was interred juſt at the entrance into the choir, where a noble monument is erected to his memory.

Sir Iſaac was of a middling ſtature, and in the latter part of his life ſomewhat inclined to be fat. His countenance was pleaſing and at the ſame time venerable. He never made uſe of ſpectacles, and loſt but one tooth during his whole life.

His temper is ſaid to have been ſo equal and mild, that no accident could diſturb it. Of this the following remarkable inſtance is related. Sir Iſaac had a favourite little dog, which he called *Diamond;* and being one day called out of his ſtudy into the next room, Diamond was left behind. When Sir Iſaac returned, having been abſent but a few minutes, he had the mortification to find, that Diamond having thrown down a lighted candle among ſome papers, the nearly finiſhed labour of many years, was in flames, and almoſt conſumed to aſhes. This loſs, as Sir Iſaac was then very far advanced in years, was irretrievable; yet without once ſtriking the dog, he only rebuked him with this exclamation, "Oh! Diamond! Diamond! thou little knoweſt the miſchief thou haſt done!

He was a great lover of peace, and would rather have choſen to remain in obſcurity than to have the calm of life ruffled by thoſe ſtorms and diſputes which genius and learning always draw upon thoſe that are peculiarly eminent for them. In contemplating his genius it preſently becomes a doubt, which of theſe endowments had the greateſt ſhare, ſagacity, penetration, ſtrength or diligence: and after all, the mark that ſeems moſt to diſtinguiſh it is, that he himſelf made the juſteſt eſtimation of it, declaring, that, if he had done the world any ſervice, it was due to nothing but induſtry and patient thought; that he kept the ſubject under conſideration conſtantly before him, and waited till the firſt dawning opened gradually, by little and little, into a full and clear light. It is ſaid, that when he had any mathematical problems or ſolutions in his mind, he would never quit the ſubject on any account. Dinner has been often three hours ready for him before he could be brought to table: and his man often ſaid, when he has been getting up in a morning, he has ſometimes begun to dreſs, and with one leg in his breeches ſat down again on the bed, where he has remained for hours before he got his clothes on. From his love of peace, no doubt, aroſe that unuſual kind of horror which he had for all diſputes; a ſteady unbroken attention, free from thoſe frequent recoilings inſeparably incident to others, was his peculiar felicity; he knew it, and he knew the value of it. No wonder then that controverſy was looked on as his bane. When ſome objections, haſtily made to his diſcoveries concerning light and colours, induced him to lay aſide the deſign he had of publiſhing his optic lectures, we find him reflecting on that diſpute, into which he was unavoidably drawn thereby, in theſe terms: "I blamed my own imprudence for parting with ſo real a bleſſing as my quiet, to run after a ſhadow." It is true this ſhadow (as Mr Fontenelle obſerves) did not eſcape him afterwards, nor did it coſt him that quiet which he ſo much valued, but proved as much a real happineſs to him as his quiet itſelf; yet this was a happineſs of his own making: he took a reſolution, from theſe diſputes, not to publiſh any more about that theory till he had put it above the reach of controverſy, by the exacteſt experiments and the ſtricteſt demonſtrations; and accordingly it has never been called in queſtion ſince. In the ſame temper, after he had ſent the manuſcript of his *Principia* to the Royal Society, with his conſent to the printing of it by them, upon Mr Hook's injuriouſly inſiſting that himſelf had demonſtrated Kepler's problem before our author, he determined, rather than be involved again in a controverſy, to ſuppreſs the third book, and was very hardly prevailed upon to alter that reſolution. It is true, the public was thereby a gainer; that book, which is indeed no more than a corollary of ſome propoſitions in the firſt, being originally drawn up in the popular way, with the deſign to publiſh it in that form; whereas he was now convinced that it would be beſt not to let it go abroad without a ſtrict demonſtration.

After all, notwithſtanding his anxious care to avoid every occaſion of breaking his intenſe application to ſtudy, he was at a great diſtance from being ſteeped in philoſophy: on the contrary, he could lay aſide his thoughts, though engaged in the moſt intricate reſearches, when his other affairs required his attendance; and as ſoon as he had leiſure, reſume the ſubject at the point where he had left off. This he ſeems to have done not ſo much by any extraordinary ſtrength of memory, as by the force of his inventive faculty to which every thing opened itſelf again with eaſe, if nothing intervened to ruffle him. The readineſs of his invention made him not think of putting his memory much to the trial: but this was the offspring of a vigorous intenſeneſs of thought, out of which he was but a common man. He ſpent, therefore, the prime of his age in thoſe abſtruſe reſearches, when his ſituation in a college gave him leiſure, and even while ſtudy was his proper profeſſion. But as ſoon as he was removed to the mint, he applied himſelf chiefly to the buſineſs of that office; and ſo far quitted mathematics and philoſophy, as not to engage in any purſuits of either kind afterwards.

The amiable quality of modeſty is repreſented as ſtanding foremoſt in the character of this great man's mind and manners. It was in reality greater than can be eaſily imagined, or will be readily believed; yet it always continued ſo without any alteration, though the whole world, ſays Fontenelle, conſpired againſt it;

and let us add, though he was thereby robbed of his inventions of fluxions. Nicholas Mercator publiſhing his *Logarithmotechnia* in 1668, where he gave the quadrature of the hyperbola by an infinite ſeries, which was the firſt appearance in the learned world of a ſeries of this ſort drawn from the particular nature of the curve, and that in a manner very new and abſtracted; Dr Barrow, then at Cambridge, where Mr Newton, at that time about 26 years of age, reſided, recollected that he had met with the ſame thing in the writings of that young gentleman; and there not confined to the hyperbola only, but extended, by general forms, to all ſorts of curves, even ſuch as are mechanical; to their quadratures, their rectifications, and their centres of gravity; to the ſolids formed by their relations, and to the ſuperficies of thoſe ſolids; ſo that, when their determinations were poſſible, the ſeries ſtopped at a certain point, or at leaſt their ſums were given by ſtated rules; and, if the abſolute determinations were impoſſible, they could yet be infinitely approximated; which is the happieſt and moſt refined method, ſays Mr Fontenelle, of ſupplying the defects of human knowledge that man's imagination could poſſibly invent. To be maſter of ſo fruitful and general a theory was a mine of gold to a geometrician; but it was a greater glory to have been the diſcoverer of ſo ſurpriſing and ingenious a ſyſtem. So that Mr Newton finding by Mercator's book, that he was in the way to it, and that others might follow in his track, ſhould naturally have been forward to open his treaſures, and ſecure the property, which conſiſted in making the diſcovery; but he contented himſelf with his treaſure which he had found, without regarding the glory. What an idea does it give us of his unparalleled modeſty, when we ſee him declaring, that he thought Mercator had entirely diſcovered his ſecret, or that others would, before he was of a proper age for writing? His MS. upon infinite ſeries was communicated to none but Mr John Collins and the lord Brounker; and even that had not been complied with, but for Dr Barrow, who would not ſuffer him to indulge his modeſty ſo much as he deſired.

It is further obſerved, concerning this part of his character, that he never talked either of himſelf or others, nor ever behaved in ſuch a manner as to give the moſt malicious cenſurers the leaſt occaſion even to ſuſpect him of vanity. He was candid and affable, and always put himſelf upon a level with his company. He never thought either his merit or his reputation ſufficient to excuſe him from any of the common offices of ſocial life; no ſingularities, either natural or affected, diſtinguiſhed him from other men. Though he was firmly attached to the church of England, he was averſe to the perſecution of the non-conformiſts. He judged of men by their manners; and the true ſchiſmatics, in his opinion, were the vicious and the wicked. Not that he confined his principles to natural religion, for he was thoroughly perſuaded of the truth of revelation; and amidſt the great variety of books which he had conſtantly before him, that which he ſtudied with the greateſt application was the Bible: and he underſtood the nature and force of moral certainty as well as he did that of a ſtrict demonſtration.

Sir Iſaac did not neglect the opportunities of doing good, when the revenues of his patrimony, and a profitable employment, improved by a prudent economy, put it in his power. We have two remarkable inſtances of his bounty and generoſity; one to Mr M'Laurin, profeſſor of mathematics at Edinburgh, to whom he offered 20l. per annum; and the other to his niece Barton, who had an annuity of 100l. per annum ſettled upon her by him. When decency upon any occaſion required expence and ſhow, he was magnificent without grudging it, and with a very good grace; at all other times, that pomp which ſeems great to low minds only, was utterly retrenched, and the expence reſerved for better uſes. He never married, and perhaps he never had leiſure to think of it. Being immerſed in profound ſtudies during the prime of his age, and afterwards engaged in an employment of great importance, and even quite taken up with the company which his merit drew to him, he was not ſenſible of any vacancy in life, nor of the want of a companion at home. He left 32,000l. at his death; but made no will, which Mr Fontenelle tells us was becauſe he thought a legacy was no gift. As to his works, beſides what were publiſhed in his lifetime, there were found after his death, among his papers, ſeveral diſcourſes upon the ſubjects of antiquity, hiſtory, divinity, chemiſtry, and mathematics, ſeveral of which were publiſhed at different times.

NEWTONIAN *Philoſophy*, the doctrine of the univerſe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Iſaac Newton.

1
Different opinions concerning this philoſophy.

The term *Newtonian Philoſophy* is applied very differently; whence divers confuſed notions relating thereto. Some authors under this philoſophy include all the corpuſcular philoſophy, conſidered as it now ſtands corrected and reformed by the diſcoveries and improvements made in ſeveral parts thereof by Sir Iſaac Newton. In which ſenſe it is that Graveſande calls his elements of phyſics, *Introductio ad Philoſophiam Newtonianam*. And in this ſenſe the Newtonian is the ſame with the new philoſophy; and ſtands contradiſtinguiſhed from the Carteſian, the Peripatetic, and the ancient Corpuſcular.

Others, by *Newtonian Philoſophy*, mean the method or order which Sir Iſaac Newton obſerves in philoſophizing; viz. the reaſoning and drawing of concluſions directly from phenomena, excluſive of all previous hypotheſes; the beginning from ſimple principles; deducing the firſt powers and laws of nature from a few ſelect phenomena, and then applying thoſe laws, &c. to account for other things. And in this ſenſe the *Newtonian philoſophy* is the ſame with the *experimental philoſophy*, and ſtands oppoſed to the ancient *Corpuſcular*.

Others, by *Newtonian philoſophy*, mean that wherein phyſical bodies are conſidered mathematically, and where geometry and mechanics are applied to the ſolution of the appearances of nature. In which ſenſe the Newtonian is the ſame with the *mechanical* and *mathematical philoſophy*.

Others again, by *Newtonian philoſophy*, underſtand that part of phyſical knowledge which Sir Iſaac Newton has handled, improved, and demonſtrated, in his *Principia*.

Others, laſtly, by *Newtonian philoſophy*, mean the new principles which Sir Iſaac Newton has brought into philoſophy; the new ſyſtem founded thereon; and the new ſolutions of phenomena thence deduced;

Newtonian Philoſophy.

or that which characterizes and diſtinguiſhes his philoſophy from all others.—Which is the ſenſe wherein we ſhall chiefly conſider it.

As to the hiſtory of this philoſophy, we have nothing to add to what has been given in the preceding article. It was firſt made public in the year 1687, by the author, then a fellow of Trinity College, Cambridge; and in the year 1713, republiſhed with conſiderable improvements.—Several authors have ſince attempted to make it plainer; by ſetting aſide many of the more ſublime mathematical reſearches, and ſubſtituting either more obvious reaſonings or experiments in lieu thereof; particularly Whiſton in his *Prælect. Phyſ. Mathemat.* Graveſande in *Element. et Inſtit.* and Dr Pemberton in his *View*.

The whole of the *Newtonian Philoſophy*, as delivered by the author, is contained in his *Principia* or *Mathematical Principles of Natural Philoſophy*. He founds his ſyſtem on the following definitions:

Definitions on which the philoſophy is founded.

1. The quantity of matter is the meaſure of the ſame, ariſing from its denſity and bulk conjunctly.—Thus air of a double denſity, in a double ſpace, is quadruple in quantity; in a triple ſpace, ſextuple in quantity, &c.

2. The quantity of motion is the meaſure of the ſame, ariſing from the velocity and quantity of matter conjunctly. This is evident, becauſe the motion of the whole is the motion of all its parts; and therefore in a body double in quantity, with equal velocity, the motion is double, &c.

Vis inſita defined and objected to.

3. The *vis inſita*, or innate force of matter, is a power of reſiſting, by which every body, as much as in it lies, endeavours to perſevere in its preſent ſtate, whether it be of reſt, or moving uniformly forward in a right line.—This definition is proved to be juſt, only by the difficulty we find in moving any thing out of its place; and this difficulty is by ſome reckoned to proceed only from gravity. They contend, that in thoſe caſes where we can prevent the force of gravity from acting upon bodies, this power of reſiſtance becomes inſenſible, and the greateſt quantities of matter may be put in motion by the very leaſt force. Thus there have been balances formed ſo exact, that when loaded with 200 weight in each ſcale, they would turn by the addition of a ſingle drachm. In this caſe 400 lb. of matter was put in motion by a ſingle drachm, *i e* by $\frac{1}{102400}$ parts of its own quantity: and even this ſmall weight, they ſay, is only neceſſary on account of the inaccuracy of the machine: ſo that we have no reaſon to ſuppoſe, that, if the friction could be entirely removed, it would take more force to move a tun weight than a grain of ſand. This objection, however, is not taken notice of by Sir Iſaac: and he beſtows on the reſiſting power above mentioned the name of *vis inertiæ*; a phraſe which is perhaps not well choſen, and with which inferior writers have endeavoured to make their readers merry at the expence of Newton. A *force of inactivity*, it has been ſaid, is a *forceleſs* force; and analogous to a *black white*, a *cold heat*, and a *tempeſtuous calm*.

Examination of the third and fourth Definitions of the firſt Book of the Principia, &c.

But objections of more importance have been made to the whole of this doctrine than thoſe which merely reſpect the term *vis inertiæ*. "An endeavour to remain at reſt (we are told*) is unneceſſary, whilſt nothing attempts to diſturb the reſt. It is likewiſe impoſſible to be conceived, as it implies a contradiction. A man, by oppoſing force to force, may endeavour not to be moved; but this oppoſition is an endeavour to *move*, not with a *deſign* to move, but by counteracting another force to *prevent* being moved. An endeavour not to move therefore cannot exiſt in bodies, becauſe it is abſurd; and if we appeal to fact, we ſhall find every body in an actual and conſtant endeavour to move." It has been likewiſe obſerved, and we think juſtly, that "if bodies could *continue* to move by any innate force, they might alſo *begin* to move by that force. For the ſame cauſe which can move a body with a given velocity at one time, could do it, if preſent, at any other time; and therefore if the force by which bodies continue in motion were innate and eſſential to them, they would begin to move of themſelves, which is not true." Newton indeed ſays that this innate force is the cauſe of motion under certain circumſtances only, or when the body is acted upon by a force impreſſed *ab extra*. But if this impreſſed force do not continue as well as begin the motion, if it ceaſe the inſtant that the impreſſion is over, and the body continue to move by its *vis inertiæ*, why is the body ever ſtopped? "If in the beginning of the motion the body, by its innate force, overcomes a certain reſiſtance of friction and air, in any following times, the force being undiminiſhed, it will overcome the ſame reſiſtance for ever. Theſe reſiſtances, therefore, could never change the ſtate of a moving body, becauſe they cannot change the quantity of its motive force. But this is contrary to univerſal experience." For theſe reaſons we are inclined to think that bodies are wholly paſſive; that they endeavour nothing; and that they continue in motion not by any innate force or *vis inſita*, but by that force, whatever it be, which begins the motion, and which, whilſt it remains with the moving body, is gradually diminiſhed, and at laſt overcome by oppoſite forces, when the body of courſe ceaſes to move.

4. An impreſſed force is an action exerted upon a body, in order to change its ſtate, either of reſt or of moving uniformly forward in a right line.——This force conſiſts in the action only; and remains no longer in the body when the action is over. For a body maintains every new ſtate it acquires by its *vis inertiæ* only.

It is here implied, and indeed fully expreſſed, that motion is not continued by the ſame power that produced it. Now there are two grounds on which the truth of this doctrine may be ſuppoſed to reſt.

"*Firſt*, On a direct proof that the impreſſed force does not remain in the body, either by ſhowing the nature of the force to be tranſitory and incapable of more than its firſt action; or that it acts only on the ſurface, and that the body eſcapes from it; or that the force is ſomewhere elſe, and not remaining in the body. But none of theſe direct proofs are offered.

"*Secondly*, It may reſt on an indirect proof, that there is in the nature of body a ſufficient cauſe for the continuance of every new ſtate acquired; and that therefore any adventitious force to continue motion, though neceſſary for its production, is ſuperfluous and inadmiſſible. As this is the very ground on which the ſuppoſition ſtands, it ought to have been indubitably certain that the innate force of the body

Newtonian Philoſop

---

* *Young's Examination of the third and fourth Definitions of the firſt Book of the Principia, &c.*

is ſufficient to perpetuate the motion it has once acquired, before the other agent, by which the motion was communicated, had been diſmiſſed from the office. But the innate force of body has been ſhown not to be that which continues its motion; and therefore the proof, that the impreſſed force does not remain in the body, fails. Nor indeed is it in this caſe deſirable to ſupport the proof; becauſe we ſhould then be left without any reaſon for the continuance of motion †." When we mention an impreſſed force, we mean ſuch a force as is communicated either at the ſurface of the body or by being diffuſed through the maſs.

5. A centripetal force is that by which bodies are drawn, impelled, or any way tend towards a point, as to a centre.—The quantity of any centripetal force may be conſidered as of three kinds, abſolute, accelerative, and motive.

6. The abſolute quantity of a centrifugal force is the meaſure of the ſame, proportional to the efficacy of the cauſe that propagates it from the centre, through the ſpaces round about.

7. The accelerative quantity of a centripetal force is the meaſure of the ſame, proportional to the velocity which it generates in a given time.

8. The motive quantity of a centripetal force is a meaſure of the ſame, proportional to the motion which it generates in a given time.—This is always known by the quantity of a force equal and contrary to it, that is juſt ſufficient to hinder the deſcent of the body.

SCHOLIA.

4 Of Time. I. Abſolute, true, and mathematical time, of itſelf, and from its own nature, flows equably, without regard to any thing external, and, by another name, is called *duration*. Relative, apparent, and common time, is ſome ſenſible and external meaſure of duration, whether accurate or not, which is commonly uſed inſtead of true time; ſuch as an hour, a day, a month, a year, &c.

5 Space. II. Abſolute ſpace, in its own nature, without regard to any thing external, remains always ſimilar and immoveable. Relative ſpace is ſome moveable dimenſion or meaſure of the abſolute ſpaces; and which is vulgarly taken for immoveable ſpace. Such is the dimenſion of a ſubterraneous, an aerial, or celeſtial ſpace, determined by its poſition to bodies, and which is vulgarly taken for immoveable ſpace; as the diſtance of a ſubterraneous, an aerial, or celeſtial ſpace, determined by its poſition in reſpect of the earth. Abſolute and relative ſpace are the ſame in figure and magnitude; but they do not remain always numerically the ſame. For if the earth, for inſtance, moves, a ſpace of our air which, relatively and in reſpect of the earth, remains always the ſame, will at one time be one part of the abſolute ſpace into which the earth paſſes; at another time it will be another part of the ſame; and ſo, abſolutely underſtood, it will be perpetually mutable.

6 Place defined. III. Place is a part of ſpace which a body takes up; and is, according to the ſpace, either abſolute or relative. Our author ſays it is *part* of ſpace; not the ſituation, nor the external ſurface of the body. For the places of equal ſolids are always equal; but their ſuperficies, by reaſon of their diſſimilar figures, are often unequal. Poſitions properly have no quantity, are they ſo much the places themſelves as the properties of places. The motion of the whole is the ſame thing with the ſum of the motions of the parts; that is, the tranſlation of the whole out of its place is the ſame thing with the ſum of the tranſlations of the parts out of their places: and therefore the place of the whole is the ſame thing with the ſum of the places of the parts; and for that reaſon it is internal, and in the whole body.

7 Of Motion. IV. Abſolute motion is the tranſlation of a body from one abſolute place into another, and relative motion the tranſlation from one relative place into another. Thus, in a ſhip under ſail, the relative place of a body is that part of the ſhip which the body poſſeſſes, or that part of its cavity which the body fills, and which therefore moves together with the ſhip; and relative reſt is the continuance of the body in the ſame part of the ſhip, or of its cavity. But real abſolute reſt is the continuance of the body in the ſame part of that immoveable ſpace in which the ſhip itſelf, its cavity, and all that it contains, is moved. Wherefore, if the earth is really at reſt, the body which relatively reſts in the ſhip will really and abſolutely move with the ſame velocity which the ſhip has on the earth. But if the earth alſo moves, the true and abſolute motion of the body will ariſe, partly from the true motion of the earth in immoveable ſpace; partly from the relative motion of the ſhip on the earth: and if the body moves alſo relatively in the ſhip, its true motion will ariſe partly from the true motion of the earth in immoveable ſpace, and partly from the relative motions as well of the ſhip on the earth as of the body in the ſhip; and from theſe relative motions will ariſe the relative motion of the body on the earth. As if that part of the earth where the ſhip is, was truly moved towards the eaſt, with a velocity of 10010 parts; while the ſhip itſelf with a freſh gale is carried towards the weſt, with a velocity expreſſed by 10 of theſe parts; but a ſailor walks in the ſhip towards the eaſt with one part of the ſaid velocity: then the ſailor will be moved truly and abſolutely in immoveable ſpace towards the eaſt with a velocity of 1001 parts; and relatively on the earth towards the weſt, with a velocity of 9 of thoſe parts.

Abſolute time, in aſtronomy, is diſtinguiſhed from relative, by the equation or correction of the vulgar time. For the natural days are truly unequal, though they are commonly conſidered as equal, and uſed for a meaſure of time: aſtronomers correct this inequality for their more accurate deducing of the celeſtial motions. It may be that there is no ſuch thing as an equable motion whereby time may be accurately meaſured. All motions may be accelerated or retarded; but the true or equable progreſs of abſolute time is liable to no change. The duration or perſeverance of the exiſtence of things remains the ſame, whether the motions are ſwift or ſlow, or none at all; and therefore ought to be diſtinguiſhed from what are only ſenſible meaſures thereof, and out of which we collect it by means of the aſtronomical equation. The neceſſity of which equation for determining the times of a phenomenon is evinced, as well from the experiments of the pendulum clock as by eclipſes of the ſatellites of Jupiter.

---

† *Young's Examination, &c.*

8
Immutability of time and ſpace.

As the order of the parts of time is immutable, ſo alſo is the order of the parts of ſpace. Suppoſe thoſe parts to be moved out of their places, and they will be moved (if we may be allowed the expreſſion) out of themſelves. For times and ſpaces are, as it were, the places of themſelves as of all other things. All things are placed in time as to order of ſucceſſion; and in ſpace as to order of ſituation. It is from their eſſence or nature that they are places; and that the primary places of things ſhould be moveable, is abſurd. Theſe are therefore the abſolute places; and tranſlations out of thoſe places are the only abſolute motions.

But becauſe the parts of ſpace cannot be ſeen, or diſtinguiſhed from one another by the ſenſes, therefore in their ſtead we uſe ſenſible meaſures of them. For, from the poſitions and diſtances of things from any body, conſidered as immoveable, we define all places; and then with reſpect to ſuch places, we eſtimate all motions, conſidering bodies as transferred from ſome of thoſe places into others. And ſo, inſtead of abſolute places and motions, we uſe relative ones; and that without any inconvenience in common affairs: but in philoſophical diſquiſitions we ought to abſtract from our ſenſes, and conſider things themſelves diſtinct from what are only ſenſible meaſures of them. For it may be, that there is no body really at reſt, to which the places and motions of others may be referred.

But we may diſtinguiſh reſt and motion, abſolute and relative, one from the other by their properties cauſes, and effects. It is a property of reſt, that bodies really at reſt do reſt in reſpect of each other. And therefore, as it is poſſible, that, in the remote regions of the fixed ſtars, or perhaps far beyond them, there may be ſome body abſolutely at reſt, though it be impoſſible to know from the poſition of bodies to one another in our regions, whether any of theſe do keep the ſame poſition to that remote body; it follows, that abſolute reſt cannot be determined from the poſition of bodies in our regions.

9
Of the motion of different bodies with reſpect to one another.

It is a property of motion, that the parts which retain given poſitions to their wholes do partake of the motion of their wholes. For all parts of revolving bodies endeavour to recede from the axis of motion; and the impetus of bodies moving forwards ariſes from the joint impetus of all the parts. Therefore if ſurrounding bodies are moved, thoſe that are relatively at reſt within them will partake of their motion. Upon which account the true and abſolute motion of a body cannot be determined by the tranſlation of it from thoſe only which ſeem to reſt; for the external bodies ought not only to appear at reſt, but to be really at reſt. For otherwiſe all included bodies, beſide their tranſlation from near the ſurrounding ones, partake likewiſe of their true motions; and though that tranſlation was not made, they would not really be at reſt, but only ſeem to be ſo. For the ſurrounding bodies ſtand in the like relation to the ſurrounded, as the exterior part of a whole does to the interior, or as the ſhell does to the kernel; but if the ſhell moves, the kernel will alſo move, as being part of the whole, without any removal from near the ſhell.

A property near akin to the preceding is, that if a place is moved, whatever is placed therein moves along with it; and therefore a body which is moved from a place in motion, partakes alſo of the motion of its place. Upon which account all motions from places in motion, are no other than parts of entire and abſolute motions; and every entire motion is compoſed of the motion of the body out of its firſt place, and the motion of this place out of its place; and ſo on, until we come to ſome immoveable place, as in the above mentioned example of the ſailor. Wherefore entire and abſolute motions can be no otherwiſe determined than by immoveable places. Now, no other places are immoveable but thoſe that from infinity to infinity do all retain the ſame given poſitions one to another; and upon this account muſt ever remain unmoved, and do thereby conſtitute what we call *immoveable ſpace*.

The cauſes by which true and relative motions are diſtinguiſhed one from the other, are the forces impreſſed upon bodies to generate motion. True motion is neither generated nor altered, but by ſome force impreſſed upon the body moved: but relative motion may be generated or altered without any force impreſſed upon the body. For it is ſufficient only to impreſs ſome force on other bodies with which the former is compared, that by their giving way, that relation may be changed, in which the relative reſt or motion of the other body did conſiſt. Again, True motion ſuffers always ſome change from any force impreſſed upon the moving body; but relative motion does not neceſſarily undergo any changes by ſuch forces. For if the ſame forces are likewiſe impreſſed on thoſe other bodies with which the compariſon is made, that the relative poſition may be preſerved; then that condition will be preſerved, in which the relative motion conſiſts. And therefore any relative motion may be changed when the true motion remains unaltered, and the relative may be preſerved when the true motion ſuffers ſome change. Upon which account true motion does by no means conſiſt in ſuch relations.

10
Abſolute and relative motion diſtinguiſhed.

The effects which diſtinguiſh abſolute from relative motion are, the forces of receding from the axis of circular motion. For there are no ſuch forces in a circular motion purely relative: but, in a true and abſolute circular motion, they are greater or leſs according to the quantity of the motion. If a veſſel, hung by a long cord, is ſo often turned about that the cord is ſtrongly twiſted, then filled with water, and let go, it will be whirled about the contrary way; and while the cord is untwiſting itſelf, the ſurface of the water will at firſt be plain, as before the veſſel began to move; but the veſſel, by gradually communicating its motion to the water, will make it begin ſenſibly to revolve, and recede by little and little from the middle, and aſcend to the ſides of the veſſel, forming itſelf into a concave figure; and the ſwifter the motion becomes, the higher will the water riſe, till at laſt, performing its revolutions in the ſame times with the veſſel, it becomes relatively at reſt in it. This aſcent of the water ſhows its endeavour to recede from the axis of its motion; and the true and abſolute circular motion of the water, which is here directly contrary to the relative, diſcovers itſelf, and may be meaſured by this endeavour. At firſt, when the relative motion in the water was greateſt, it produced no endeavour to recede from the axis; the water ſhowed no tendency to the circumference, nor any aſcent towards the ſides of the veſſel, but remained of a plane ſurface; and therefore its true circular motion had not yet begun. But afterwards, when the relative motion of the water had decreaſed, the aſcent thereof towards the ſides of the veſſel proved its endeavour to recede from the axis; and this endeavour ſhowed the real circular motion of the water perpetually increaſing, till it had acquired its greateſt quantity, when the water reſted relatively in the veſſel. And therefore this endeavour does not depend upon any tranſlation of the water in reſpect of the ambient bodies; nor can true circular motion be defined by ſuch tranſlations. There is only one real circular motion of any one revolving body, correſponding to only one power of endeavouring to recede from its axis of motion, as its proper and adequate effect: but relative motions in one and the ſame body are innumerable, according to the various relations it bears to external bodies; and, like other relations, are altogether deſtitute of any real effect, otherwiſe than they may perhaps participate of that only true motion. And therefore, in the ſyſtem which ſuppoſes that our heavens, revolving below the ſphere of the fixed ſtars, carry the planets along with them, the ſeveral parts of thoſe heavens and the planets, which are indeed relatively at reſt in their heavens, do yet really move. For they change their poſition one to another, which never happens to bodies truly at reſt; and being carried together with the heavens, participate of their motions, and, as parts of revolving wholes, endeavour to recede from the axis of their motion.

Wherefore relative quantities are not the quantities themſelves whoſe names they bear, but thoſe ſenſible meaſures of them, either accurate or inaccurate, which are commonly uſed inſtead of the meaſured quantities themſelves. And then, if the meaning of words is to be determined by their uſe, by the names *time*, *ſpace*, *place*, and *motion*, their meaſures are properly to be underſtood; and the expreſſion will be unuſual and purely mathematical, if the meaſured quantities themſelves are meant.

It is indeed a matter of great difficulty to diſcover, and effectually to diſtinguiſh, the true motions of particular bodies from thoſe that are only apparent: becauſe the parts of that immoveable ſpace in which thoſe motions are performed, do by no means come under the obſervation of our ſenſes. Yet we have ſome things to direct us in this intricate affair; and theſe ariſe partly from the apparent motions which are the difference of the true motions, partly from the forces which are the cauſes and effects of the true motions. For inſtance, if two globes, kept at a given diſtance one from the other by means of a cord that connects them, were revolved about their common centre of gravity; we might, from the tenſion of the cord, diſcover the endeavour of the globes to recede from the axis of motion, and from thence we might compute the quantity of their circular motions. And then, if any equal forces ſhould be impreſſed at once on the alternate faces of the globes to augment or diminiſh their circular motions, from the increaſe or decreaſe of the tenſion of the cord we might infer the increment or decrement of their motions; and thence would be found on what faces thoſe forces ought to be impreſſed that the motions of the globes might be moſt augmented; that is, we might diſcover their hindermoſt faces, or thoſe which follow in the circular motion. But the faces which follow being known, and conſequently the oppoſite ones that precede, we ſhould likewiſe know the determination of their motions. And thus we might find both the quantity and determination of this circular motion, even in an immenſe vacuum, where there was nothing external or ſenſible, with which the globes might be compared. But now, if in that ſpace ſome remote bodies were placed that kept always a given poſition one to another, as the fixed ſtars do in our regions; we could not indeed determine from the relative tranſlation of the globes among thoſe bodies, whether the motion did belong to the globes or to the bodies. But if we obſerved the cord, and found that its tenſion was that very tenſion which the motions of the globes required, we might conclude the motion to be in the globes, and the bodies to be at reſt; and then, laſtly, from the tranſlation of the globes among the bodies, we ſhould find the determination of their motions.

Having thus explained himſelf, Sir Iſaac propoſes to ſhow how we are to collect the true motions from their cauſes, effects, and apparent differences; and *vice verſa*, how, from the motions, either true or apparent, we may come to the knowledge of their cauſes and effects. In order to this, he lays down the following axioms or laws of motion.

11 Laws of motion.

12 Objections to the firſt law.

1. EVERY BODY PERSEVERES IN ITS STATE OF REST, OR OF UNIFORM MOTION IN A RIGHT LINE, UNLESS IT IS COMPELLED TO CHANGE THAT STATE BY FORCES IMPRESSED UPON IT.—Sir Iſaac's proof of this axiom is as follows: "Projectiles perſevere in their motions, ſo far as they are not retarded by the reſiſtance of the air, or impelled downwards by the force of gravity. A top, whoſe parts, by their coheſion, are perpetually drawn aſide from rectilinear motions, does not ceaſe its rotation otherwiſe than as it is retarded by the air. The greater bodies of the planets and comets, meeting with leſs reſiſtance in more free ſpaces, preſerve their motions, both progreſſive and circular, for a much longer time."—Notwithſtanding this demonſtration, however, the axiom hath been violently diſputed. It hath been argued, that bodies continue in their ſtate of motion becauſe they are ſubjected to the continual impulſe of an inviſible and ſubtile fluid, which always pours in from behind, and of which all places are full. It hath been affirmed that motion is as natural to this fluid as reſt is to all other matter. It is ſaid, moreover, that it is impoſſible we can know in what manner a body would be influenced by moving forces if it was entirely deſtitute of gravity. According to what we can obſerve, the momentum of a body, or its tendency to move, depends very much on its gravity. A heavy cannon-ball will fly to a much greater diſtance than a light one, though both are actuated by an equal force. It is by no means clear, therefore, that a body totally deſtitute of gravity would have any proper momentum of its own; and if it had no momentum, it could not continue its motion for the ſmalleſt ſpace of time after the moving power was withdrawn. Some have imagined that matter was capable of beginning motion of itſelf, and conſequently that the axiom was falſe; becauſe we ſee plainly that matter in ſome caſes hath a tendency

Newtonian Philoſophy.

to change from a ſtate of motion to a ſtate of reſt, and from a ſtate of reſt to a ſtate of motion. A paper appeared on this ſubject in the firſt volume of the Edinburgh Phyſical and Literary Eſſays; but the hypotheſis never gained any ground.

2. THE ALTERATION OF MOTION IS EVER PROPORTIONAL TO THE MOTIVE FORCE IMPRESSED; AND IS MADE IN THE DIRECTION OF THE RIGHT LINE IN WHICH THAT FORCE IS IMPRESSED.—Thus, if any force generates a certain quantity of motion, a double force will generate a double quantity, whether that force be impreſſed all at once, or in ſucceſſive moments. To this law no objection of conſequence has ever been made. It is founded on this ſelf-evident truth, that every effect muſt be proportional to its cauſe. Mr Young, who ſeems to be very ambitious of detecting the errors of Newton, finds fault indeed with the expreſſions in which the law is ſtated; but he owns, that if thus expreſſed, *The alteration of motion is proportional to the actions or reſiſtances which produce it, and is in the direction in which the actions or reſiſtances are made*, it would be unexceptionable.

13 Objections to the third law.

3. TO EVERY ACTION THERE ALWAYS IS OPPOSED AN EQUAL RE-ACTION: OR THE MUTUAL ACTION OF TWO BODIES UPON EACH OTHER ARE ALWAYS EQUAL, AND DIRECTED TO CONTRARY PARTS.—This axiom is alſo diſputed by many. In the above-mentioned paper in the Phyſical Eſſays, the author endeavours to make a diſtinction between re-action and reſiſtance; and the ſame attempt has been made by Mr Young. "When an action generates no motion (ſays he), it is certain that its effects have been deſtroyed by a contrary and equal action. When an action generates two contrary and equal motions, it is alſo evident that mutual actions were exerted, equal and contrary to each other. All caſes where one of theſe conditions are not found, are exceptions to the truth of the law. If a finger preſſes againſt a ſtone, the ſtone, if it does not yield to the preſſure, preſſes as much upon the finger: but if the ſtone yields, it re-acts leſs than the finger acts; and if it ſhould yield with all the momentum that the force of the preſſure ought to generate, which it would do if it were not impeded by friction, or a medium, it would not re-act at all. So if the ſtone drawn by a horſe, follows after the horſe, it does not re-act ſo much as the horſe acts; but only ſo much as the velocity of the ſtone is diminiſhed by friction, and it is the re-action of friction only, not of the ſtone. The ſtone does not re-act becauſe it does not act, it reſiſts, but reſiſtance is not action.

"In the loſs of motion from a ſtriking body, equal to the gain in the body ſtruck, there is a plain ſolution without requiring any re-action. The motion *loſt* is identically that which is *found* in the other body; this ſuppoſition accounts for the whole phenomenon in the moſt ſimple manner. If it be not admitted, but the ſolution by re-action is inſiſted upon, it will be incumbent on the party to account for the whole effect of communication of motion; otherwiſe he will lie under the imputation of rejecting a ſolution which is ſimple, obvious, and perfect; for one complex, unnatural, and incomplete. However this may be determined, it will be allowed, that the circumſtances mentioned, afford no ground for the inference, that action and re-action are equal, ſince appearances may be explained in another way" (A).

Others grant that Sir Iſaac's axiom is very true in reſpect to terreſtrial ſubſtances; but they affirm, that, in

---

(A) If there be a perfect reciprocity betwixt an impinging body and a body at reſt ſuſtaining its impulſe, may we not at our pleaſure conſider either body as the agent, and the other as the reſiſtant? Let a moving body, A, paſs from north to ſouth, an equal body B at reſt, which receives the ſtroke of A, act upon A from ſouth to north, and A reſiſt in a contrary direction, both inelaſtic: let the motion reciprocally communicated be called ſix. Then B at reſt communicates to A ſix degrees of motion towards the north, and receives ſix degrees towards the ſouth. B having no other motion than the ſix degrees it communicated, will, by its equal and contrary loſs and gain, remain in equilibrio. Let the original motion of A have been twelve, then A having received a contrary action equal to ſix, ſix degrees of its motion will be deſtroyed or in equilibrio; conſequently, a motive force as ſix will remain to A towards the ſouth, and B will be in equilibrio, or at reſt. A will then endeavour to move with ſix degrees, or half its original motion, and B will remain at reſt as before. A and B being equal maſſes, by the laws of communication three degrees of motion will be communicated to B, or A with its ſix degrees will act with three, and B will re-act alſo with three. B then will act on A from ſouth to north equal to three, while it is acted upon or reſiſted by A from north to ſouth, equal alſo to three, and B will remain at reſt as before; A will alſo have its ſix degrees of motion reduced to one half by the contrary action of B, and only three degrees of motion will remain to A, with which it will yet endeavour to move; and finding B ſtill at reſt, the ſame proceſs will be repeated till the whole motion of A is reduced to an infinitely ſmall quantity, B all the while remaining at reſt, and there will be no communication of motion from A to B, which is contrary to experience.

Let a body, A, whoſe maſs is twelve, at reſt, be impinged upon firſt by B, having a maſs as twelve, and a velocity as four, making a momentum of 48; and ſecondly by C, whoſe maſs is ſix, and velocity eight, making a momentum of 48 equal to B, the three bodies being inelaſtic. In the firſt caſe, A will become poſſeſſed of a momentum of 24, and 24 will remain to B; and, in the ſecond caſe, A will become poſſeſſed of a momentum of 32, and 16 will remain to C, both bodies moving with equal velocities after the ſhock, in both caſes, by the laws of percuſſion. It is required to know, if in both caſes A reſiſts equally, and if B and C act equally? if the actions and reſiſtances are equal, how does A in one caſe deſtroy 24 parts of B's motion, and in the other caſe 32 parts of C's motion, by an equal reſiſtance? And how does B communicate in one caſe 24 degrees of motion, and C 32, by equal actions? If the actions and reſiſtances are unequal, it is aſked how the ſame maſs can reſiſt differently to bodies impinging upon it with equal momenta, and how bodies in theſe, both action and re-action, are the effects of gravity. Subſtances void of gravity would have no momentum; and without this they could not act; they ſhould be moved by the leaſt force, and therefore could not reſiſt or re-act. If therefore there is any fluid which is the cauſe of gravity, though ſuch fluid could act upon terreſtrial ſubſtances, yet theſe could not re-act upon it; becauſe they have no force of their own, but depend entirely upon it for their momentum. In this manner, ſay they, we may conceive that the planets circulate, and all the operations of nature are carried on by means of a ſubtile fluid; which being perfectly active, and the reſt of matter altogether paſſive, there is neither reſiſtance nor loſs of motion. See Motion.

From the preceding axiom Sir Iſaac draws the following corollaries.

1. A body by two forces conjoined will deſcribe the diagonal of a parallelogram in the ſame time that it would deſcribe the ſides by thoſe forces apart.

2. Hence we may explain the compoſition of any one direct force out of any two oblique ones, viz. by making the two oblique forces the ſides of a parallelogram, and the direct one the diagonal.

3. The quantity of motion, which is collected by taking the ſum of the motions directed towards the ſame parts, and the difference of thoſe that are directed to contrary parts, ſuffers no change from the action of bodies among themſelves; becauſe the motion which one body loſes is communicated to another: and if we ſuppoſe friction and the reſiſtance of the air to be abſent, the motion of a number of bodies which mutually impelled one another would be perpetual, and its quantity always equal.

4. The common centre of gravity of two or more bodies does not alter its ſtate of motion or reſt by the actions of the bodies among themſelves; and therefore the common centre of gravity of all bodies acting upon each other (excluding outward actions and impediments) is either at reſt, or moves uniformly in a right line.

5. The motions of bodies included in a given ſpace are the ſame among themſelves, whether that ſpace is at reſt, or moves uniformly forward in a right line without any circular motion. The truth of this is evidently ſhown by the experiment of a ſhip; where all motions happen after the ſame manner, whether the ſhip is at reſt, or proceeds uniformly forward in a ſtraight line.

6. If bodies, anyhow moved among themſelves, are urged in the dirction of parallel lines by equal accelerative forces, they will all continue to move among themſelves, after the ſame manner as if they had been urged by no ſuch forces.

The whole of the mathematical part of the Newtonian philoſophy depends on the following lemmas; of which the firſt is the principal.

Lem. I. Quantities, and the ratios of quantities, which in any finite time converge continually to equality, and before that time approach nearer the one to the other than by any given difference, become ultimately equal. If you deny it; ſuppoſe them to be ultimately unequal, and let D be their ultimate difference. Therefore they cannot approach nearer to equality than by that given difference D; which is againſt the ſuppoſition.

Newtonian Philoſophy.

14 Objections to the firſt lemma,

Concerning the meaning of this lemma philoſophers are not agreed; and unhappily it is the very fundamental poſition on which the whole of the ſyſtem reſts. Many objections have been raiſed to it by people who ſuppoſed themſelves capable of underſtanding it. They ſay, that it is impoſſible we can come to an end of any infinite ſeries, and therefore that the word *ultimate* can in this caſe have no meaning. In ſome caſes the lemma is evidently falſe. Thus, ſuppoſe there are two quantities of matter A and B, the one containing half a pound, and the other a third part of one. Let both be continually divided by 2; and though their ratio, or the proportion of the one to the other, doth not vary, yet the difference between them perpetually becomes leſs, as well as the quantities themſelves, until both the difference and quantities themſelves become leſs than any aſſignable quantity: yet the difference will never totally vaniſh, nor the quantities become equal, as is evident from the two following ſeries.

$$\begin{array}{lcccccccccc}
 & \frac{1}{2} & \frac{1}{4} & \frac{1}{8} & \frac{1}{16} & \frac{1}{32} & \frac{1}{64} & \frac{1}{128} & \frac{1}{256} & \frac{1}{512} & \frac{1}{1024}, \&c. \\
 & \frac{1}{3} & \frac{1}{6} & \frac{1}{12} & \frac{1}{24} & \frac{1}{48} & \frac{1}{96} & \frac{1}{192} & \frac{1}{384} & \frac{1}{768} & \frac{1}{1536}, \&c. \\
\text{Diff.} & \frac{1}{6} & \frac{1}{12} & \frac{1}{24} & \frac{1}{48} & \frac{1}{96} & \frac{1}{192} & \frac{1}{384} & \frac{1}{768} & \frac{1}{1536} & \frac{1}{3072}, \&c.
\end{array}$$

Thus we ſee, that though the difference is continually diminiſhing, and that in a very large proportion, there is no hope of its vaniſhing, or the quantities becoming equal. In like manner, let us take the proportions or ratios of quantities, and we ſhall be equally unſucceſsful. Suppoſe two quantities of matter, one containing 8 and the other 10 pounds; theſe quantities already have to each other the ratio of 8 to 10, or of 4 to 5; but let us add 2 continually to each of them, and though the ratios continually come nearer to that of equality, it is in vain to hope for a perfect coincidence. Thus,

$$\begin{array}{lccccccccc}
 & 8 & 10 & 12 & 14 & 16 & 18 & 20 & 22 & 24, \&c. \\
 & 10 & 12 & 14 & 16 & 18 & 20 & 22 & 24 & 26, \&c. \\
\text{Ratio} & \frac{4}{5} & \frac{5}{6} & \frac{6}{7} & \frac{7}{8} & \frac{8}{9} & \frac{9}{10} & \frac{10}{11} & \frac{11}{12} & \frac{12}{13}, \&c.
\end{array}$$

15 Objection anſwered.

For this and his other lemmas Sir Iſaac makes the following apology. "Theſe lemmas are premiſed, to avoid the tediouſneſs of deducing perplexed demonſtrations *ad abſurdum*, according to the method of ancient geometers. For demonſtrations are more contracted by the method of indiviſibles: but becauſe the hypotheſis of indiviſibles ſeems ſomewhat harſh, and therefore that method is reckoned leſs geometrical, I choſe rather to reduce the demonſtrations of the following propoſitions to the firſt and laſt ſums and ratios of naſcent and evaneſcent quantities, that is, to the limits of thoſe ſums and ratios; and ſo to premiſe, as ſhort as I could, the demonſtrations of thoſe limits.

For

---

bodies poſſeſſed of equal momenta can exert different actions, it being admitted that bodies reſiſt proportional to their maſſes, and that their power of overcoming reſiſtance is proportional to their momenta?

It is incumbent on thoſe who maintain the doctrine of univerſal re-action, to free it from theſe difficulties and apparent contradictions.

For hereby the ſame thing is performed as by the method of indiviſibles; and now thoſe principles being demonſtrated, we may uſe them with more ſafety.—Therefore, if hereafter I ſhould happen to conſider quantities as made up of particles, or ſhould uſe little curve lines for right ones; I would not be underſtood to mean indiviſibles, but evaneſcent diviſible quantities; not the ſums and ratios of determinate parts, but always the limits of ſums and ratios; and that the force of ſuch demonſtrations always depends on the method laid down in the foregoing lemmas.

"Perhaps it may be objected, that there is no ultimate proportion of evaneſcent quantities, becauſe the proportion, before the quantities have vaniſhed, is not the ultimate, and, when they are vaniſhed, is none.—But by the ſame argument it may be alleged, that a body arriving at a certain place, and there ſtopping, has no ultimate velocity; becauſe the velocity before the body comes to the place is not its ultimate velocity; when it is arrived, it has none. But the anſwer is eaſy: for by the ultimate velocity is meant that with which the body is moved, neither before it arrives at its place and the motion ceaſes, nor after; but at the very inſtant it arrives; that is, that velocity with which the body arrives at its laſt place, and with which the motion ceaſes. And in like manner, by the ultimate ratio of evaneſcent quantities is to be underſtood the ratio of the quantities, not before they vaniſh, nor afterwards, but with which they vaniſh. In like manner, the firſt ratio of naſcent quantities is that with which they begin to be. And the firſt or laſt ſum is that with which they begin and ceaſe to be (or to be augmented and diminiſhed). There is a limit which the velocity at the end of the motion may attain, but not exceed; and this is the ultimate velocity. And there is the like limit in all quantities and proportions that begin and ceaſe to be. And, ſince ſuch limits are certain and definite, to determine the ſame is a problem ſtrictly geometrical. But whatever is geometrical we may be allowed to make uſe of in determining and demonſtrating any other thing that is likewiſe geometrical.

"It may alſo be objected, that if the ultimate ratios of evaneſcent quantities are given, their ultimate magnitudes will be alſo given; and ſo all quantities will conſiſt of indiviſibles, which is contrary to what Euclid has demonſtrated concerning incommenſurables, in the 10th book of his Elements. But this objection is founded on a falſe ſuppoſition. For thoſe ultimate ratios with which quantities vaniſh are not truly the ratios of ultimate quantities, but limits towards which the ratios of quantities decreaſing continually approach."

Lem. II. If in any figure AacE (Plate CCCXLV. N° 1.) terminated by the right line Aa, AE, and the curve acE, there be inſcribed any number of parallelograms Ab, Bc, Cd, &c. comprehended under equal baſes AB, BC, CD, &c. and the ſides Bb, Cc, Dd, &c. parallel to one ſide Aa of the figure; and the parallelograms $aKbl$, $bLcm$, $cMdn$, &c. are completed.—Then if the breadth of thoſe parallelograms be ſuppoſed to be diminiſhed, and their number augmented *in infinitum*; the ultimate ratios which the inſcribed figure $AKbLcMdD$, the circumſcribed figure $AalbmcndoE$, and curvilinear figure $AabcdE$, will have to one another, are ratios of equality.—For the difference of the inſcribed and circumſcribed figures is the ſum of the parallelograms Kl, Lm, Mn, Do; that is (from the equality of all their baſes), the rectangle under one of their baſes Kb, and the ſum of their altitudes Aa, that is, the rectangle $ABla$.—But this rectangle, becauſe its breadth AB is ſuppoſed diminiſhed *in infinitum*, becomes leſs than any given ſpace. And therefore by Lem. I. the figures inſcribed and circumſcribed become ultimately equal the one to the other; and much more will the intermediate curvilinear figure be ultimately equal to either.

Lem. III. The ſame ultimate ratios are alſo ratios of equality, when the breadths AB, BC, CD, &c. of the parallelograms are unequal, and are all diminiſhed *in infinitum*.—The demonſtration of this differs but little from that of the former.

In his ſucceeding lemmas, Sir Iſaac goes on to prove, in a manner ſimilar to the above, that the ultimate ratios of the ſine, chord, and tangent of arcs infinitely diminiſhed, are ratios of equality, and therefore that in all our reaſonings about theſe we may ſafely uſe the one for the other:—that the ultimate form of evaneſcent triangles made by the arc, chord, and tangent, is that of ſimilitude, and their ultimate ratio is that of equality; and hence, in reaſonings about ultimate ratios, we may ſafely uſe theſe triangles for each other, whether made with the ſine, the arc, or the tangent.—He then ſhows ſome properties of the ordinates of curvilinear figures; and proves that the ſpaces which a body deſcribes by any finite force urging it, whether that force is determinate and immutable, or is continually augmented or continually diminiſhed, are, in the very beginning of the motion, one to the other in the duplicate ratio of the powers. And, laſtly, Having added ſome demonſtrations concerning the evaneſcence of angles of contact, he proceeds to lay down the mathematical part of his ſyſtem, and which depends on the following theorems:

Theor. I. The areas which revolving bodies deſcribe by radii drawn to an immoveable centre of force, lie in the ſame immoveable planes, and are proportional to the times in which they are deſcribed.—For, ſuppoſe the time to be divided into equal parts, and in the firſt part of that time, let the body by its innate force deſcribe the right line AB (N° 2.); in the ſecond part of that time, the ſame would, by Law 1. if not hindered, proceed directly to c along the line $Bc = AB$; ſo that by the radii AS, BS, cS, drawn to the centre, the equal areas ASB, BSc, would be deſcribed. But, when the body is arrived at B, ſuppoſe the centripetal force acts at once with a great impulſe, and turning aſide the body from the right line Bc, compels it afterwards to continue its motion along the right line BC. Draw cC parallel to BS, meeting BC in C; and at the end of the ſecond part of the time, the body, by Cor. 1. of the Laws, will be found in C, in the ſame plane with the triangle ASB. Join SC; and becauſe SB and cC are parallel, the triangle SBC will be equal to the triangle SBC, and therefore alſo to the triangle SAB. By the like argument, if the centripetal force acts ſucceſſively in C, D, E, &c. and makes the body in each ſingle particle of time to deſcribe the right lines CD, DE, EF, &c. they will all lie in the ſame plane ; and the triangle SCD will be equal to the triangle SBC, and SDE to SCD, and SEF to SDE. And therefore, in equal times, equal areas are deſcribed in one immoveable plane ; and, by compoſition, any ſums SADS, SAFS, of thoſe areas are, one to the other, as the times in which they are deſcribed. Now, let the number of thoſe triangles be augmented, and their ſize diminiſhed *in infinitum ;* and then, by the preceding lemmas, their ultimate perimeter ADF will be a curve line : and therefore the centripetal force by which the body is perpetually drawn back from the tangent of this curve will act continually ; and any deſcribed areas SADS, SAFS, which are always proportional to the times of deſcription, will, in this caſe alſo, be proportional to thoſe times Q. E. D.

Cor. 1. The velocity of a body attracted towards an immoveable centre, in ſpaces void of reſiſtance, is reciprocally as the perpendicular let fall from that centre on the right line which touches the orbit. For the velocities in theſe places, A, B, C, D, E, are as the baſes AB, BC, DE, EF, of equal triangles ; and theſe baſes are reciprocally as the perpendiculars let fall upon them.

Cor. 2. If the chords AB, BC, of two arcs, ſucceſſively deſcribed in equal times by the ſame body, in ſpaces void of reſiſtance, are completed into a parallelogram ABCV, and the diagonal BV of this parallelogram, in the poſition which it ultimately acquires when thoſe arcs are diminiſhed *in infinitum*, is produced both ways, it will paſs through the centre of force.

Cor. 3. If the chords AB, BC, and DE, EF, of arcs deſcribed in equal times, in ſpaces void of reſiſtance, are completed into the parallelograms ABCV, DEFZ, the forces in B and E are one to the other in the ultimate ratio of the diagonals BV, EZ, when thoſe arcs are diminiſhed *in infinitum.* For the motions BC and EF of the body (by Cor. 1. of the laws), are compounded of the motions B*c*, BV and E*f*, EZ ; but BV and EZ, which are equal to C*c*= and F*f*, in the demonſtration of this propoſition, were generated by the impulſes of the centripetal force in B and E, and are therefore proportional to thoſe impulſes.

Cor. 4. The forces by which bodies, in ſpaces void of reſiſtance, are drawn back from rectilinear motions, and turned into curvilinear orbits, are one to another as the verſed ſines of arcs deſcribed in equal times ; which verſed ſines tend to the centre of force, and biſect the chords when theſe arcs are diminiſhed to infinity. For ſuch verſed ſines are the halfs of the diagonals mentioned in Cor. 3.

Cor. 5. And therefore thoſe forces are to the force of gravity, as the ſaid verſed ſines to the verſed ſines perpendicular to the horizon of thoſe parabolic arcs which projectiles deſcribe in the ſame time.

Cor. 6. And the ſame things do all hold good (by Cor. 5. of the laws) when the planes in which the bodies are moved, together with the centres of force, which are placed in thoſe planes, are not at reſt, but move uniformly forward in right lines.

Theor. II. Every body that moves in any curve line deſcribed in a plane, and, by a radius drawn to a point either immoveable or moving forward with an uniform rectilinear motion, deſcribes about that point areas proportional to the times, is urged by a centripetal force directed to that point.

Case I. For every body that moves in a curve line is (by Law 1.) turned aſide from its rectilinear courſe by the action of ſome force that impels it ; and that force by which the body is turned off from its rectilinear courſe, and made to deſcribe in equal times the leaſt equal triangles SAB, SBC, SCD, &c. about the immoveable point S, (by Prop. 40. E. 1. and Law 2.) acts in the place B according to the direction of a line parallel to C ; that is, in the direction of the line BS ; and in the place C according to the direction of a line parallel to *d* D, that is, in the direction of the line CS, &c. ; and therefore acts always in the direction of lines tending to the immoveable point S. Q. E. D.

Case II. And (by Cor. 5. of the laws) it is indifferent whether the ſuperficies in which a body deſcribes a curvilinear figure be quieſcent, or moves together with the body, the figure deſcribed, and its point S, uniformly forward in right lines.

Cor. 1. In non-reſiſting ſpaces or mediums, if the the areas are not proportional to the times, the forces are not directed to the point in which the radii meet ; but deviate therefrom *in conſequentia*, or towards the parts to which the motion is dirjected, if the deſcription of the areas is accelerated ; but *in antecedentia* if retarded.

Cor. 2. And even in reſiſting mediums, if the deſcription of the areas is accelerated, the directions of the forces deviate from the point in which the radii meet, towards the parts to which the motion tends.

Scholium.

A body may be urged by a centripetal force compounded of ſeveral forces. In which caſe the meaning of the propoſition is, that the force which reſults out of all tends to the point S. But if any force acts perpetually in the direction of lines perpendicular to the deſcribed ſurface, this force will make the body to deviate from the plane of its motion, but will neither augment nor diminiſh the quantity of the deſcribed ſurface ; and is therefore not to be neglected in the compoſition of forces.

Theor. III. Every body that, by a radius drawn to the centre of another body, howſoever moved, deſcribes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of all the accelerative force by which that other body is impelled.—The demonſtration of this is a natural conſequence of the theorem immediately preceding.

Hence, if the one body L, by a radius drawn to the other body T, deſcribes areas proportional to the times, and from the whole force by which the firſt body L is urged, (whether that force is ſimple, or, according to Cor. 2. of the laws, compounded of ſeveral forces), we ſubduct that whole accelerative force by which the other body is urged ; the whole remaining force by which the firſt body is urged will tend to the other body T, as its centre.

And *vice verſa*, if the remaining force tends nearly to the other body T, thoſe areas will be nearly proportional to the times.

Newtonian Philoſophy.

If the body L, by a radius drawn to the other body T, deſcribes areas, which, compared with the times, are very unequal, and that other body T be either at reſt, or moves uniformly forward in a right line, the action of the centripetal force tending to that other body T is either none at all, or it is mixed and combined with very powerful actions of other forces: and the whole force compounded of them all, if they are many, is directed to another (immoveable or moveable) centre. The ſame thing obtains when the other body is actuated by any other motion whatever; provided that centripetal force is taken which remains after ſubducting that whole force acting upon that other body T.

SCHOLIUM.

Becauſe the equable deſcription of areas indicates that a centre is reſpected by that force with which the body is moſt affected, and by which it is drawn back from its rectilinear motion, and retained in its orbit, we may always be allowed to uſe the equable deſcription of areas as an indication of a centre about which all circular motion is performed in free ſpaces.

THEOR. IV. The centripetal forces of bodies which by equable motions deſcribe different circles, tend to the centres of the ſame circles; and are one to the other as the ſquares of the arcs deſcribed in equal times applied to the radii of circles.—For theſe forces tend to the centres of the circles, (by Theor. 2. and Cor. 2. Theor. 1.) and are to one another as the verſed ſines of the leaſt arcs deſcribed in equal times, (by Cor. 4. Theor. 1.) that is, as the ſquares of the ſame arcs applied to the diameters of the circles, by one of the lemmas; and therefore, ſince thoſe arcs are as arcs deſcribed in any equal times, and the diameters are as the radii, the forces will be as the ſquares of any arcs deſcribed in the ſame time, applied to the radii of the circles. Q. E. D.

COR. 1. Therefore, ſince thoſe arcs are as the velocities of the bodies, the centripetal forces are in a ratio compounded of the duplicate ratio of the velocities directly, and of the ſimple ratio of the radii inverſely.

COR. 2. And ſince the periodic times are in a ratio compounded of the ratio of the radii directly, and the ratio of the velocities inverſely; the centripetal forces are in a ratio compounded of the ratio of the radii directly, and the duplicate ratio of the periodic times inverſely.

COR. 3. Whence, if the periodic times are equal, and the velocities therefore as the radii, the centripetal forces will be alſo as the radii; and the contrary.

COR. 4. If the periodic times and the velocities are both in the ſubduplicate ratio of the radii, the centripetal forces will be equal among themſelves; and the contrary.

COR. 5. If the periodic times are as the radii, and therefore the velocities equal, the centripetal forces will be reciprocally as the radii; and the contrary.

COR. 6. If the periodic times are in the ſeſquiplicate ratio of the radii, and therefore the velocities reciprocally in the ſubduplicate ratio of the radii, the centripetal forces will be in the duplicate ratio of the radii inverſely; and the contrary.

COR. 7. And univerſally, if the periodic time is as any power R^n of the radius R, and therefore the velocity reciprocally as the power R^{n-1} of the radius, the centripetal force will be reciprocally as the power R^{2n-1} of the radius; and the contrary.

COR. 8. The ſame things all hold concerning the times, the velocities, and forces, by which bodies deſcribe the ſimilar parts of any ſimilar figures, that have their centres in a ſimilar poſition within thoſe figures, as appears by applying the demonſtrations of the preceding caſes to thoſe. And the application is eaſy, by only ſubſtituting the equable deſcription of areas in the place of equable motion, and uſing the diſtances of the bodies from the centres inſtead of the radii.

COR. 9. From the ſame demonſtration it likewiſe follows, that the arc which a body uniformly revolving in a circle by means of a given centripetal force deſcribes in any time, is a mean proportional between the diameter of the circle, and the ſpace which the ſame body, falling by the ſame given force, would deſcend through in the ſame given time.

"By means of the preceding propoſition and its corollaries (ſays Sir Iſaac), we may diſcover the proportion of a centripetal force to any other known force, ſuch as that of gravity. For if a body by means of its gravity revolves in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the deſcent of heavy bodies, the time of one entire revolution, as well as the arc deſcribed in any given time, is given (by Cor. 9. of this theorem). And by ſuch propoſitions Mr Huygens, in his excellent book *De Horologio Oſcillatorio*, has compared the force of gravity with the centrifugal forces of revolving bodies.

The preceding propoſition may alſo be demonſtrated in the following manner. In any circle ſuppoſe a polygon to be inſcribed of any number of ſides. And if a body, moved with a given velocity along the ſides of the polygon, is reflected from the circle at the ſeveral angular points; the force with which, at every reflection it ſtrikes the circle, will be as its velocity: and therefore the ſum of the forces, in a given time, will be as that velocity and the number of reflections conjunctly; that is, (if the ſpecies of the polygon be given), as the length deſcribed in that given time, and increaſed or diminiſhed in the ratio of the ſame length to the radius of the circle; that is, as the ſquare of that length applied to the radius; and therefore, if the polygon, by having its ſides diminiſhed *in infinitum*, coincides with the circle, as the ſquare of the arc deſcribed in a given time applied to the radius. This is the centrifugal force, with which the body impels the circle; and to which the contrary force, wherewith the circle continually repels the body towards the centre, is equal.

On theſe principles hangs the whole of Sir Iſaac Newton's mathematical philoſophy. He now ſhows how to find the centre to which the forces impelling any body are directed, having the velocity of the body given: and finds the centrifugal force to be always as the verſed ſine of the naſcent arc directly, and as the ſquare of the time inverſely; or directly as the ſquare of the velocity, and inverſely as the chord of the naſcent arc. From theſe premiſes he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this whether the central point is near or at an immenſe diſtance; ſo that all the lines drawn from it may be taken for parallels. The ſame thing he ſhows with regard to bodies revolving in ſpirals, ellipſes, hyperbolas, or parabolas.—Having the figures of the orbits given, he ſhows alſo how to find the velocities and moving powers; and, in ſhort, ſolves all the moſt difficult problems relating to the celeſtial bodies with an aſtoniſhing degree of mathematical ſkill. Theſe problems and demonſtrations are all contained in the firſt book of the *Principia:* but to give an account of them here would far exceed our limits; neither would many of them be intelligible, excepting to firſt-rate mathematicians.

16
Rules for philoſophical reaſoning.

In the ſecond book, Sir Iſaac treats of the properties of fluids, and their powers of reſiſtance; and here he lays down ſuch principles as entirely overthrow the doctrine of Des Cartes's vortices, which was the faſhionable ſyſtem in his time. In the third book, he begins particularly to treat of the natural phenomena, and apply them to the mathematical principles formerly demonſtrated; and, as a neceſſary preliminary to this part, he lays down the following rules for reaſoning in natural philoſophy.

1. We are to admit no more cauſes of natural things than ſuch as are both true and ſufficient to explain their natural appearances.

2. Therefore to the ſame natural effects we muſt always aſſign, as far as poſſible, the ſame cauſes.

3. The qualities of bodies which admit neither intenſion nor remiſſion of degrees, and which are found to belong to all bodies within the reach of our experiments, are to be eſteemed the univerſal qualities of all bodies whatſoever.

4. In experimental philoſophy, we are to look upon propoſitions collected by general induction from phenomena as accurately or very nearly true, notwithſtanding any contrary hypotheſes that may be imagined, till ſuch time as other phenomena occur, by which they may either be made more accurate, or liable to exceptions.

The phenomena firſt conſidered are, 1. That the ſatellites of Jupiter by radii drawn to the centre of their primary, deſcribe areas proportional to the times of their deſcription; and that their periodic times, the fixed ſtars being at reſt, are in the ſeſquiplicate ratio of their diſtances from its centre. 2. The ſame thing is likewiſe obſerved of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, and Saturn, with their ſeveral orbits encompaſs the ſun. 4. The fixed ſtars being ſuppoſed at reſt, the periodic times of the five primary planets, and of the earth, about the ſun, are in the ſeſquiplicate proportion of their mean diſtances from the ſun. 5. The primary planets, by radii drawn to the earth, deſcribe areas no ways proportionable to the times: but the areas which they deſcribe by radii drawn to the ſun are proportional to the times of deſcription. 6. The moon, by a radius drawn to the centre of the earth, deſcribes an area proportional to the time of deſcription. All theſe phenomena are undeniable from aſtronomical obſervations, and are explained at large under the article Astronomy. The mathematical demonſtrations are next applied by Sir Iſaac Newton in the following propoſitions:

Prop. I. The forces by which the ſatellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet; and are reciprocally as the ſquares of the diſtances of thoſe ſatellites from that centre. The former part of this propoſition appears from Theor. 2. or 3. and the latter from Cor. 6. of Theor. 4.; and the ſame thing we are to underſtand of the ſatellites of Saturn.

Prop. II. The forces by which the primary planets are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the ſun; and are reciprocally as the ſquares of the diſtances from the ſun's centre. The former part of this propoſition is manifeſt from Phenomenon 5. juſt mentioned, and from Theor. 2.; the latter from Phenomenon 4. and Cor. 6. of Theor. 4. But this part of the propoſition is with great accuracy deducible from the quieſcence of the aphelion points. For a very ſmall aberration from the reciprocal duplicate proportion would produce a motion of the apſides, ſenſible in every ſingle revolution, and in many of them enormouſly great.

Prop. III. The force by which the moon is retained in its orbit, tends towards the earth; and is reciprocally as the ſquare of the diſtance of its place from the centre of the earth. The former part of this propoſition is evident from Phenom. 5. and Theor. 2.; the latter from Phenom. 6. and Theor. 2. or 3. It is alſo evident from the very ſlow motion of the moon's apogee; which, in every ſingle revolution, amounting but to 3° 3′ *in conſequentia*, may be neglected: and this more fully appears from the next propoſition.

Prop. IV. The moon gravitates towards the earth, and by the force of gravity is continually drawn off from a rectilinear motion, and retained in its orbit.—The mean diſtance of the moon from the earth in the ſyzigies in ſemidiameters of the latter, is about $60\frac{1}{2}$. Let us aſſume the mean diſtance of 60 ſemidiameters in the ſyzigies; and ſuppoſe one revolution of the moon in reſpect of the fixed ſtars to be completed in 27^{d}. 7^{h}. 43′, as aſtronomers have determined; and the circumference of the earth to amount to 123,249,600 Paris feet. Now, if we imagine the moon, deprived of all motion, to be let go, ſo as to deſcend towards the earth with the impulſe of all that force by which it is retained in its orbit, it will, in the ſpace of one minute of time, deſcribe in its fall $15\frac{1}{2}$ Paris feet. For the verſed ſine of that arc which the moon, in the ſpace of one minute of time, deſcribes by its mean motion at the diſtance of 60 ſemidiameters of the earth, is nearly $15\frac{1}{12}$ Paris feet; or more accurately, 15 feet 1 inch and one line $\frac{4}{9}$. Wherefore ſince that force, in approaching to the earth, increaſes in the reciprocal duplicate proportion of the diſtance; and, upon that account, at the ſurface of the earth is 60x60 times greater than that at the moon; a body in our regions, falling with that force, ought, in the ſpace of one minute of time, to deſcribe $60\times60\times15\frac{1}{12}$ Paris feet; and in the ſpace of one ſecond of time to deſcribe $15\frac{1}{12}$ of thoſe feet; or, more accurately, 15 feet 1 inch, Newtonian hiloſophy.

Newtoni Ph

1 inch, 1 line $\frac{4}{9}$. And with this very force we actually find that bodies here on earth do really deſcend.—For a pendulum oſcillating ſeconds in the latitude of Paris, will be three Paris feet and $8\frac{1}{2}$ lines in length, as Mr Huygens has obſerved. And the ſpace which a heavy body deſcribes by falling one ſecond of time is to half the length of the pendulum in the duplicate ratio of the circumference of the circle to its diameter; and is therefore 15 Paris feet, 1 inch 1 line $\frac{7}{9}$. And therefore the force by which the moon is retained in its orbit, becomes at the very ſurface of the earth, equal to the force of gravity which we obſerve in heavy bodies there. And therefore (by Rule 1. and 2.) the force by which the moon is retained in its orbit is that very ſame force which we commonly call *gravity*. For were gravity another force different from that, then bodies deſcending to the earth with the joint impulſe of both forces would fall with a double velocity, and, in the ſpace of one ſecond of time, would deſcribe $30\frac{1}{6}$ Paris feet; altogether againſt experience.

The demonſtration of this propoſition may be more diffuſely explained after the following manner: Suppoſe ſeveral moons to revolve about the earth, as in the ſyſtem of Jupiter or Saturn, the periodic times of thoſe moons would (by the argument of induction) obſerve the ſame law which Kepler found to obtain among the planets; and therefore their centripetal forces would be reciprocally as the ſquares of the diſtances from the centre of the earth, by Prop. I. Now, if the loweſt of theſe were very ſmall, and were ſo near the earth as almoſt to touch the tops of the higheſt mountains, the centripetal force thereof, retaining it in its orbit, would be very nearly equal to the weights of any terreſtrial bodies that ſhould be found upon the tops of theſe mountains; as may be known from the foregoing calculation. Therefore, if the ſame little moon ſhould be deſerted by its centrifugal force that carries it through its orbit, it would deſcend to the earth; and that with the ſame velocity as heavy bodies do actually deſcend with upon the tops of thoſe very mountains, becauſe of the equality of forces that oblige them both to deſcend. And if the force by which that loweſt moon would deſcend were different from that of gravity, and if that moon were to gravitate towards the earth, as we find terreſtrial bodies do on the tops of mountains, it would then deſcend with twice the velocity, as being impelled by both theſe forces conſpiring together. Therefore, ſince both theſe forces, that is, the gravity of heavy bodies, and the centripetal forces of the moons, reſpect the centre of the earth, and are ſimilar and equal between themſelves, they will (by Rule 1. and 2.) have the ſame cauſe. And therefore the force which retains the moon in its orbit, is that very force which we commonly call *gravity*; becauſe otherwiſe, this little moon at the top of a mountain muſt either be without gravity, or fall twice as ſwiftly as heavy bodies uſe to do.

Having thus demonſtrated that the moon is retained in its orbit by its gravitation towards the earth, it is eaſy to apply the ſame demonſtration to the motions of the other ſecondary planets, and of the primary planets round the ſun, and thus to ſhow that gravitation prevails throughout the whole creation; after which, Sir Iſaac proceeds to ſhow from the ſame principles that the heavenly bodies gravitate towards each other, and contain different quantities of matter, or have different denſities in proportion to their bulks.

Prop. V. All bodies gravitate towards every planet; and the weights of bodies towards the ſame planet, at equal diſtances from its centre, are proportional to the quantities of matter they contain.

It has been confirmed by many experiments, that all ſorts of heavy bodies (allowance being made for the inequality of retardation by ſome ſmall reſiſtance of the air,) deſcend to the earth from equal heights in equal times; and that equality of times we may diſtinguiſh to a great accuracy by the help of pendulums. Sir Iſaac Newton tried the thing in gold, ſilver, lead, glaſs, ſand, common ſalt, wood, water, and wheat. He provided two wooden boxes, round and equal; filled the one with wood, and ſuſpended an equal weight of gold in the centre of oſcillation of the other. The boxes hanging by equal threads of 11 feet, made a couple of pendulums, perfectly equal in weight and figure, and equally receiving the reſiſtance of the air. And placing the one by the other, he obſerved them to play together forwards and backward, for a long time, with equal vibrations. And therefore the quantity of matter in the gold was to the quantity of matter in the wood, as the action of the motive force (or *vis motrix*) upon all the gold, to the action of the ſame upon all the wood; that is, as the weight of the one to the weight of the other. And the like happened in the other bodies. By theſe experiments, in bodies of the ſame weight, he could manifeſtly have diſcovered a difference of matter leſs than the thouſandth part of the whole, had any ſuch been. But without all doubt, the nature of gravity towards the planets, is the ſame as towards the earth. For ſhould we imagine our terreſtrial bodies removed to the orb of the moon, and there, together with the moon, deprived of all motion, to be let go, ſo as to fall together towards the earth; it is certain, from what we have demonſtrated before, that in equal times, they would deſcribe equal ſpaces with the moon, and of conſequence are to the moon in quantity of matter, as their weights to its weight. Moreover, ſince the ſatellites of Jupiter perform their revolutions in times which obſerve the ſeſquiplicate proportion of their diſtances from Jupiter's centre, their accelerative gravities towards Jupiter will be reciprocally as the ſquares of their diſtances from Jupiter's centre; that is, equal at equal diſtances. And therefore, theſe ſatellites, if ſuppoſed to fall towards Jupiter from equal heights, would deſcribe equal ſpaces in equal times, in like manner as heavy bodies do on our earth. And by the ſame argument if the circumſolar planets were ſuppoſed to be let fall at equal diſtances from the ſun, they would, in their deſcent towards the ſun, deſcribe equal ſpaces in equal times. But forces, which equally accelerate unequal bodies, muſt be as thoſe bodies: that is to ſay, the weights of the planets towards the ſun muſt be as their quantities of matter. Further, That the weights of Jupiter and his ſatellites towards the ſun are proportional to the ſeveral quantities of their matter, appears from the exceeding regular motions of the ſatellites. For if ſome of theſe bodies were more ſtrongly attracted to the ſun in proportion to their quantity of matter than others, the motions of the ſatellites would be diſturbed by that inequality of attraction. If, at equal diſtances from the ſun, any ſatellite, in proportion to the quantity of its matter, did gravitate towards the ſun, with a force greater than Jupiter in proportion to his, according to any given proportion, ſuppoſe of *d* to *e*; then the diſtance between the centres of the ſun and of the ſatellite's orbit would be always greater than the diſtance between the centres of the ſun and of Jupiter nearly in the ſubduplicate of that proportion. And if the ſatellite gravitated towards the ſun with a force leſs in the proportion of *e* to *d*, the diſtance of the centre of the ſatellite's orb from the ſun would be leſs than the diſtance of the centre of Jupiter's from the ſun in the ſubduplicate of the ſame proportion. Therefore, if, at equal diſtances from the ſun, the accelerative gravity of any ſatellite towards the ſun were greater or leſs than the accelerating gravity of Jupiter towards the ſun but by $\frac{1}{1000}$ part of the whole gravity; the diſtance of the centre of the ſatellite's orbit from the ſun would be greater or leſs than the diſtance of Jupiter from the ſun by $\frac{1}{2000}$ part of the whole diſtance; that is, by a fifth part of the diſtance of the utmoſt ſatellite from the centre of Jupiter; an eccentricity of the orbit which would be very ſenſible. But the orbits of the ſatellites are concentric to Jupiter; therefore the accelerative gravities of Jupiter, and of all its ſatellites, towards the ſun, are equal among themſelves. And by the ſame argument, the weight of Saturn and of his ſatellites towards the ſun, at equal diſtances from the ſun, are as their ſeveral quantities of matter; and the weights of the moon and of the earth towards the ſun, are either none, or accurately proportional to the maſſes of matter which they contain.

But further, the weights of all the parts of every planet towards any other planet are one to another as the matter in the ſeveral parts. For if ſome parts gravitated more, others leſs, than in proportion to the quantity of their matter; then the whole planet, according to the ſort of parts with which it moſt abounds, would gravitate more or leſs than in proportion to the quantity of matter in the whole. Nor is it of any moment whether theſe parts are external or internal. For if, as an inſtance, we ſhould imagine the terreſtrial bodies with us to be raiſed up to the orb of the moon, to be there compared with its body; if the weights of ſuch bodies were to the weights of the external parts of the moon as the quantities of matter in the one and in the other reſpectively, but to the weights of the internal parts in a greater or leſs proportion; then likewiſe the weights of thoſe bodies would be to the weight of the whole moon in a greater or leſs proportion; againſt what we have ſhowed above.

Cor. 1. Hence the weights of bodies do not depend upon their forms and textures. For if the weights could be altered with the forms, they would be greater or leſs, according to the variety of forms in equal matter; altogether againſt experience.

Cor. 2. Univerſally, all bodies about the earth gravitate towards the earth; and the weights of all, at equal diſtances from the earth's centre, are as the quantities of matter which they ſeverally contain. This is the quality of all bodies within the reach of our experiments; and therefore (by Rule 3.) to be affirmed of all bodies whatſoever. If ether, or any other body, were either altogether void of gravity, or were to gravitate leſs in proportion to its quantity of matter; then, becauſe (according to Ariſtotle, Des Cartes, and others) there is no difference betwixt that and other bodies, but in mere form of matter, by a ſucceſſive change from form to form, it might be changed at laſt into a body of the ſame condition with thoſe which gravitate moſt in proportion to their quantity of matter; and, on the other hand, the [illegible]vieſt bodies, acquiring the firſt form of that body, might by degrees quite loſe their gravity. And therefore the weights would depend upon the forms of bodies, and with thoſe forms might be changed, contrary to what was proved in the preceding corollary.

Cor. 3. All ſpaces are not equally full. For if all ſpaces were equally full, then the ſpecific gravity of the fluid which fills the region of the air, on account of the extreme denſity of the matter, would fall nothing ſhort of the ſpecific gravity of quickſilver or gold, or any other the moſt denſe body; and therefore, neither gold, nor any other body, could deſcend in air. For bodies do not deſcend in fluids, unleſs they are ſpecifically heavier than the fluids. And if the quantity of matter in a given ſpace can by any rarefaction be diminiſhed, what ſhould hinder a diminution to infinity?

Cor. 4. If all the ſolid particles of all bodies are of the ſame denſity, nor can be rarefied without pores, a void ſpace or vacuum muſt be granted. [By bodies of the ſame denſity, our author means thoſe whoſe *vires inertiæ* are in the proportion of their bulks.]

Prop. VI. That there is a power of gravity tending to all bodies, proportional to the ſeveral quantities of matter which they contain.

That all the planets mutually gravitate one towards another, we have proved before; as well as that the force of gravity towards every one of them, conſidered apart, is reciprocally as the ſquare of the diſtance of places from the centre of the planet. And thence it follows, that the gravity tending towards all the planets is proportional to the matter which they contain.

Moreover, ſince all the parts of any planet *A* gravitate towards any other planet *B*, and the gravity of every part is to the gravity of the whole as the matter of the part to the matter of the whole; and (by Law 3.) to every action correſponds an equal re-action: therefore the planet *B* will, on the other hand, gravitate towards all the parts of the planet *A*; and its gravity towards any one part will be to the gravity towards the whole, as the matter of the part to the matter of the whole. *Q. E. D.*

Cor. 1. Therefore the force of gravity towards any whole planet, ariſes from, and is compounded of, the forces of gravity towards all its parts. Magnetic and electric attractions afford us examples of this. For all attraction towards the whole ariſes from the attractions towards the ſeveral parts. The thing may be eaſily underſtood in gravity, if we conſider a greater planet as formed of a number of leſſer planets, meeting together in one globe. For hence it would appear that the force of the whole muſt ariſe from the forces of the component parts. If it be objected, that, according to this law, all bodies with us muſt mutually gravitate one towards another, whereas no ſuch gravitation anywhere appears; it is anſwered, that, ſince the gravitation towards theſe bodies is to the gravitation towards the whole earth, as theſe bodies are to the whole earth, the gravitation towards them muſt be far leſs than to ewtonian ilosophy.

fall under the obſervation of our ſenſes. [The experiments with regard to the attraction of mountains, however, have now further elucidated this point.]

Cor. 2. The force of gravity towards the ſeveral equal particles of any body, is reciprocally as the ſquare of the diſtance of places from the particles.

Prop. VII. In two ſpheres mutually gravitating each towards the other, if the matter, in places on all ſides round about and equidiſtant from the centres, is ſimilar; the weight of either ſphere towards the other will be reciprocally as the ſquare of the diſtance between their centres.

For the demonſtration of this, ſee the *Principia*, Book I. Prop. lxxv. and lxxvi.

Cor. 1. Hence we may find and compare together the weights of bodies towards different planets. For the weights of bodies revolving in circles about planets are as the diameters of the circles directly, and the ſquares of their periodic times reciprocally; and their weights at the ſurfaces of the planets, or at any other diſtances from their centres, are (by this prop.) greater or leſs, in the reciprocal duplicate proportion of the diſtances. Thus from the periodic times of Venus, revolving about the ſun, in 224d. 16$\frac{3}{4}$h.; of the utmoſt circumjovial ſatellite revolving about Jupiter, in 16d. 16$\frac{8}{15}$h.; of the Huygenian ſatellite about Saturn in 15d. 22$\frac{2}{3}$h.; and of the moon about the earth in 27d. 7h. 43′; compared with the mean diſtance of Venus from the ſun, and with the greateſt heliocentric elongations of the outmoſt circumjovial ſatellite from Jupiter's centre, 8′ 16″; of the Huygenian ſatellite from the centre of Saturn, 3′ 4″; and of the moon from the earth, 10′ 33″; by computation our author found, that the weight of equal bodies, at equal diſtances from the centres of the ſun, of Jupiter, of Saturn, and of the earth, towards the ſun, Jupiter, Saturn, and the earth, were one to another as $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$ reſpectively. Then, becauſe as the diſtances are increaſed or diminiſhed, the weights are diminiſhed or increaſed in a duplicate ratio; the weights of equal bodies towards the ſun, Jupiter, Saturn, and the earth, at the diſtances 10000, 997, 791, and 109, from their centres, that is, at their very ſuperficies, will be as 10000, 943, 529, and 435 reſpectively.

Cor. 2. Hence likewiſe we diſcover the quantity of matter in the ſeveral planets. For their quantities of matter are as the forces of gravity at equal diſtances from their centres, that is, in the ſun, Jupiter, Saturn, and the earth, as 1, $\frac{1}{1067}$, $\frac{1}{3021}$, and $\frac{1}{169282}$, reſpectively. If the parallax of the ſun be taken greater or leſs than 10″ 30‴, the quantity of matter in the earth muſt be augmented or diminiſhed in the triplicate of that proportion.

Cor. 3. Hence alſo we find the denſities of the planets. For (by Prop. lxxii. Book I.) the weights of equal and ſimilar bodies towards ſimilar ſpheres, are, at the ſurfaces of thoſe ſpheres, as the diameters of the ſpheres. And therefore the denſities of diſſimilar ſpheres are as thoſe weights applied to the diameters of the ſpheres. But the true diameters of the ſun, Jupiter, Saturn, and the earth, were one to another as 10000, 997, 791, and 109; and the weights towards the ſame, as 10000, 943, 529, and 435 reſpectively; and therefore their denſities are as 100, 94$\frac{1}{2}$, 67, and 400. The denſity of the earth, which comes out by this computation, does not depend upon the parallax of the ſun, but it is determined by the parallax of the moon, and therefore is here truly defined. The ſun therefore is a little denſer than Jupiter, and Jupiter than Saturn, and the earth four times denſer than the ſun; for the ſun, by its great heat, is kept in a ſort of a rarefied ſtate. The moon alſo is denſer than the earth.

Newtonian Philoſophy. Newton.

Cor. 4. The ſmaller the planets are, they are, *cæteris paribus*, of ſo much the greater denſity. For ſo the powers of gravity on their ſeveral ſurfaces come nearer to equality. They are likewiſe, *cæteris paribus*, of the greater denſity as they are nearer to the ſun. So Jupiter is more denſe than Saturn, and the earth than Jupiter. For the planets were placed at different diſtances from the ſun, that, according to their degrees of denſity, they might enjoy a greater or leſs proportion of the ſun's heat. Our water, if it were removed as far as the orb of Saturn, would be converted into ice, and in the orb of Mercury would quickly fly away in vapour. For the light of the ſun, to which its heat is proportional, is ſeven times denſer in the orb of Mercury than with us: and by the thermometer Sir Iſaac found, that a ſevenfold heat of our ſummer ſun will make water boil. Nor are we to doubt, that the matter of Mercury is adapted to its heat, and is therefore more denſe than the matter of our earth; ſince, in a denſer matter, the operations of nature require a ſtronger heat.

It is ſhown in the ſcholium of Prop. xxii. Book II. of the *Principia*, that, at the height of 200 miles above the earth, the air is more rare than it is at the ſuperficies of the earth, in the ratio of 30 to 0,0000000000003998, or as 75,000000000000 to 1 nearly. And hence the planet Jupiter, revolving in a medium of the ſame denſity with that ſuperior air, would not loſe by the reſiſtance of the medium the 1000000th part of its motion in 1000000 years. In the ſpaces near the earth, the reſiſtance is produced only by the air, exhalations, and vapours. When theſe are carefully exhauſted by the air pump from under the receiver, heavy bodies fall within the receiver with perfect freedom, and without the leaſt ſenſible reſiſtance; gold itſelf, and the lighteſt down, let fall together, will deſcend with equal velocity; and though they fall through a ſpace of four, ſix, and eight feet, they will come to the bottom at the ſame time; as appears from experiments that have often been made. And therefore the celeſtial regions being perfectly void of air and exhalations, the planets and comets meeting no ſenſible reſiſtance in thoſe ſpaces, will continue their motions through them for an immenſe ſpace of time.

Newton (Richard) D. D. the founder of Hertford college, is a man of whom we regret that we can give but a ſuperficial and rather a vague account. By one writer he is ſaid to have been a Northamptonſhire gentleman; by another, we are told that his father enjoyed at Lavendon Grange in Bucks a moderate eſtate, which is ſtill in the family, though he lived in a houſe of Lord Northampton's in Yardley-Chaſe, where in 1675 our doctor was born. All agree that the family from which he ſprung had long been reſpectable, though its fortunes had been much injured during the great rebellion.

The ſubject of this article was educated at Weſtminſter ſchool, and from that foundation elected to a ſtudentſhip of Chriſt-Church, Oxford. At what age he was admitted into the univerſity we have no certain information; but in the liſt of graduates he is thus diſtinguiſhed: "Newton (Richard,) Chriſt-church, M. A. April 12. 1701; B. D. March 18. 1707; Hart-hall, D. D. December 7. 1710." He was appointed a tutor in Chriſt-church as ſoon as he was of the requiſite ſtanding in his college, and diſcharged the duties of that important office with honour to himſelf and advantage to the ſociety of which he was a member. From Oxford he was called (we know not at what preciſe period) into Lord Pelham's family, to ſuperintend the education of the late duke of Newcaſtle and his brother Mr Pelham; and by both theſe illuſtrious perſons he was ever remembered with the moſt affectionate regard. In 1710 he was by Dr Aldrich, the celebrated dean of Chriſt-church, inducted principal of Hart-hall, which was then an appendage to Exeter college. From this ſtate of dependance Dr Newton wreſted it againſt much oppoſition, eſpecially from the learned Dr Conybeare, afterwards dean of Chriſt-church and biſhop of Briſtol. In no conteſt, it has been obſerved, were ever two men more equally matched; and the papers that paſſed between them, like Junius's letters, deſerved to be collected for the energetic beauty of their ſtyle and the ingenuity of their arguments. Dr Newton, however, proved ſucceſsful; and in 1740 obtained a charter, converting Hart-hall into Hertford college; of which, at a conſiderable expence to himſelf, and with great aid from his numerous friends, he was thus the founder and firſt head.

Though this excellent man was Mr Pelham's tutor, and, if report be true, had by him been more than once employed to furniſh king's ſpeeches, he never received the ſmalleſt preferment from his pupil when firſt miniſter: and when that ſtateſman was aſked, why he did not place in a proper ſtation the able and meritorious Dr Newton? his reply was, "How could I do it? he never aſked me." He was not, however, neglected by all the great. Dr Compton, biſhop of London, who had a juſt ſenſe of his merits, had, at an early period of his life, collated him to the rectory of Sudbury in the county of Northampton, which he held together with the headſhip of Hart-hall. He reſided for ſome years on that living, and diſcharged all the parts of his office with exemplary care and fidelity. Amongſt other particulars he read the prayers of the liturgy in his church at ſeven o'clock in the evening of every week-day (hay-time and harveſt excepted), for the benefit of ſuch of his pariſhioners as could then aſſemble for public devotion. When he left the place, returning again to Oxford about 1724, he enjoined his curates to obſerve the ſame pious practice; and was fortunate enough to have three ſucceſſively who trode in the ſteps of their worthy principal. Being always an enemy to pluralities with cure of ſouls, he exerted his utmoſt endeavours from time to time with Dr Gibſon, Biſhop Compton's ſucceſſor in the ſee of London, for leave to reſign his rectory in favour of his curate. To the reſignation his lordſhip could have no objection; but being under ſome kind of engagement to confer the living on another, Dr Newton retained it himſelf, but beſtowed all the emoluments upon works of charity in the pariſh, and curates who ſo faithfully diſcharged their duty. Dr Sherlock, who ſucceeded Biſhop Gibſon, being under no engagement of a like nature, very readily granted Dr Newton's requeſt, by accepting his reſignation, and collating to the rectory Mr Saunders, who was the laſt of his curates. Upon a vacancy of the public orator's place at Oxford, the head of Hertford college offered himſelf a candidate; but as the race is not always to the ſwift, nor the battle to the ſtrong, Dr Digby Coates carried the point againſt him. He was afterwards promoted to a canonry of Chriſt-church, but did not long enjoy it; for in April 1753 death deprived the world of this excellent man in the 78th year of his age.

He was allowed to be as polite a ſcholar, and as accompliſhed a gentleman, as almoſt any of the age in which he lived. In cloſeneſs of argument, and perſpicuity of ſtyle, he had no ſuperior. Never was any private perſon employed in more truſts, nor were truſts ever diſcharged with greater integrity. He was a zealous friend to religion, the univerſity, the clergy, and the poor; and ſuch was his liberality of ſentiment, that he admitted to his friendſhip every man, whatever might be his religious creed, who was earneſtly employed in the ſame good works with himſelf—the promotion of virtue and unaffected piety. Of his works we have ſeen only his *Theophraſtus*, which was publiſhed after his death; and his *Pluralities Indefenſible*; but he publiſhed ſeveral other things during his life, and left a volume of ſermons prepared for the preſs at his death.

Newton (Thomas), late lord biſhop of Briſtol and dean of St Paul's, London, was born on the firſt of January 1704. His father, John Newton, was a conſiderable brandy and cyder merchant, who, by his induſtry and integrity, having acquired what he thought a competent fortune, left off trade ſeveral years before he died.

He received the firſt part of his education in the free ſchool of Litchfield; a ſchool which, the biſhop obſerves with ſome kind of exultation, had at all times ſent forth ſeveral perſons of note and eminence; from Biſhop Smaldridge and Mr Wollaſton, to Dr Johnſon and Mr Garrick.

From Litchfield he was removed to Weſtminſter ſchool, in 1717, under the care of Dr Friend and Dr Nicoll.

During the time he was at Weſtminſter, there were, he obſerves, more young men who made a diſtinguiſhed figure afterwards in the world, than perhaps at any other period, either before or ſince. He particularly mentions William Murray, the late earl of Mansfield, with whom he lived on terms of the higheſt friendſhip to the laſt.

He continued ſix years at Weſtminſter ſchool, five of which he paſſed in the college. He afterwards went to Cambridge, and entered at Trinity college. Here he conſtantly reſided eight months at leaſt in every year, till he had taken his Bachelor of Arts degree. Being choſen Fellow of his college, he came afterwards to ſettle in London. As it had been his inclination from a child, and as he was alſo deſigned for holy orders, he had ſufficient time to prepare himſelf, and compoſed ſome ſermons, that he might have a ſtock in hand when he entered on the miniſtry. His title for orders was his fellowſhip; and he was ordained deacon in December 1729, and prieſt in the February following, by Biſhop Gibſon.

At his firſt ſetting out in his office, he was curate at St George's, Hanover-ſquare; and continued for ſeveral years aſſiſtant preacher to Dr Trebeck. His firſt preferment was that of reader and afternoon preacher at Groſvenor Chapel, in South Audley ſtreet.

This introduced him to the family of Lord Tyrconnel, to whoſe ſon he became tutor. He continued in this ſituation for many years, very much at his eaſe, and on terms of great intimacy and friendſhip with Lord and Lady Tyrconnel, "without ſo much (ſays he) as an unkind word or a cool look ever intervening."

In the ſpring of 1744, he was, through the intereſt of the earl of Bath (who was his great friend and patron, and whoſe friendſhip and patronage were returned by grateful acknowledgments and the warmeſt encomiums), preſented to the rectory of St Mary le Bow; ſo that he was 40 years old before he obtained any living.

At the commencement of 1745, he took his doctor's degree. In the ſpring of 1747 he was choſen lecturer of St George's, Hanover-ſquare, by a moſt reſpectable veſtry of noblemen and gentlemen of high diſtinction. In Auguſt following he married his firſt wife, the eldeſt daughter of Dr Trebeck; an unaffected, modeſt, decent young woman, with whom he lived very happy in mutual love and harmony near ſeven years.

In 1749 he publiſhed his edition of Milton's Paradiſe Loſt, which (ſays he, very modeſtly) it is hoped hath not been ill received by the public, having, in 1775, gone through eight editions. After the Paradiſe Loſt, it was judged (ſays he) proper that Dr Newton ſhould alſo publiſh the Paradiſe Regained, and other poems of Milton; but theſe things he thought detained him from other more material ſtudies, though he had the good fortune to gain by them more than Milton did by all his works put together. But his greateſt gain (he ſays) was their firſt introducing him to the friendſhip and intimacy of two ſuch men as Biſhop Warburton and Dr Jortin, whoſe works will ſpeak for them better than any private commendation.

In 1754 he loſt his father, at the age of 83; and within a few days his wife, at the age of 38. This was the ſevereſt trial he ever underwent, and almoſt overwhelmed him. At that time he was engaged in writing his Diſſertations on the Prophecies; and happy it was for him: for in any affliction he never found a better or more effectual remedy than plunging deep into ſtudy, and fixing his thoughts as intenſely as he poſſibly could upon other ſubjects. The firſt volume was publiſhed the following winter; but the other did not appear till three years afterwards; and as a reward for his paſt and an incitement to future labours, he was appointed, in the mean time, to preach Boyle's lecture. The biſhop informs us, that 1250 copies of the Diſſertations were taken at the firſt impreſſion, and 1000 at every other edition: and "though (ſays he) ſome things have been ſince publiſhed upon the ſame ſubjects, yet they ſtill hold up their head above water, and having gone through five editions, are again prepared for another. Abroad, too, their reception hath not been unfavourable, if accounts from thence may be depended upon." They were tranſlated into the German and Daniſh languages; and received the warmeſt encomiums from perſons of learning and rank.

In the ſpring of 1757, he was made prebendary of Weſtminſter, in the room of Dr Green, and promoted to the deanery of Saliſbury. In October following, he he was made ſub-almoner to his majeſty. This he owed to Biſhop Gilbert. He married a ſecond wife in September 1761. She was the widow of the Rev. Mr Hand, and daughter of John Lord Viſcount Liſburn. In the ſame month he kiſſed his majeſty's hand for his biſhopric.

In the winter of 1764, Dr Stone, the primate of Ireland, died. Mr Grenville ſent for Biſhop Newton, and in the moſt obliging manner deſired his acceptance of the primacy. Having maturely weighed the matter in his mind, he declined the offer.

In 1768 he was made dean of St Paul's. His ambition was now fully ſatisfied; and he firmly reſolved never to aſk for any thing more.

From this time to his death, ill health was almoſt his conſtant companion. It was wonderful that ſuch a poor, weak, and ſlender thread as the biſhop's life, ſhould be ſpun out to ſuch an amazing length as it really was. In the autumn of 1781 (uſually the moſt favourable part of the year to him) he laboured under repeated illneſſes: and on Saturday the 9th of February 1782, he began to find his breath much affected by the froſt. His complaints grew worſe and worſe till the Thurſday following. He got up at five o'clock, and was placed in a chair by the fire; complained to his wife how much he had ſuffered in bed, and repeated to himſelf that portion of the Pſalms, "O my God, I cry unto thee in the day time," &c. &c. About ſix o'clock he was left by his apothecary in a quiet ſleep. Between ſeven and eight he awoke, and appeared rather more eaſy, and took a little refreſhment. He continued dozing till near nine, when he ordered his ſervant to come and dreſs him, and help him down ſtairs. As ſoon as he was dreſſed, he inquired the hour, and bid his ſervant open the ſhutter and look at the dial of St Paul's. The ſervant anſwered, it was upon the ſtroke of nine. The biſhop made an effort to take out his watch, with an intent to ſet it; but ſunk down in his chair, and expired without a ſigh or the leaſt viſible emotion, his countenance ſtill retaining the ſame placid appearance which was ſo peculiar to him when alive. Of his numerous works, his Diſſertations on the Prophecies are by much the moſt valuable. His learning was undoubtedly very conſiderable; but he ſeldom exhibits evidence of a very vigorous mind. On one occaſion, indeed, he appears to have thought with freedom; for we believe he was the firſt dignitary of the church of England who avowed his belief of the final reſtitution of all things to harmony and happineſs.

NEWTYA, a port little known, on the coaſt between Goa the capital of the Portugueſe ſettlements in India, and the Engliſh ſettlement of Bombay. Mr Rennel conjectures it to be the *Nitrias* of Pliny; near which the pirates cruized for the Roman ſhip. The ſame writer places it near to 15° 52′ 30″ North Latitude, and 73° 16′ 30″ Eaſt Longitude.

NEXI, among the Romans, perſons free born, who for debt were reduced to a ſtate of ſlavery. By the laws of the twelve tables it was ordained, that inſolvent debtors ſhould be given up to their creditors to be bound in fetters and cords, whence they were called *Nexi*; and though they did not entirely loſe the rights of freemen, yet they were often treated more harſhly than the ſlaves themſelves. If any one was indebted to ſeveral perſons, and could not within ſixty days find a cautioner, his body according to ſome, but according to others his effects, might be cut in pieces, and divided among his creditors. This latter opinion ſeems by much the moſt probable, as Livy mentions a law by which creditors had a right to attach the goods but not the perſons of their debtors.

NEYTRECHT, a town of Upper Hungary, capital of a county of the ſame name, with a biſhop's ſee; ſeated on the river *Neitra*, 40 miles north-eaſt of Preſburg. E. Long. 17. 49. N. Lat. 48. 28.

NGAN-KING-FOU, a city of China, and capital of the weſtern part of the province of Kiang-nan. It is governed by a particular viceroy, who keeps a large garriſon in a fort built on the banks of the river Yang-tſe-kiang. Its ſituation is delightful; its commerce and riches render it very conſiderable; and every thing that goes from the ſouthern part of China to Nan-king muſt paſs through it. All the country belonging to it is level, pleaſant, and fertile. It has under its juriſdiction only ſix cities of the third claſs.

NGO-KIA, a Chineſe drug, of which the compoſition will no doubt appear as ſingular as the numerous properties aſcribed to it. In the province Chang-tong, near Ngo-hien, a city of the third claſs, is a well formed by nature, which is reckoned to be ſeventy feet in depth, and which has a communication, as the Chineſe ſay, with ſome ſubterranean lake, or other large reſervoir. The water drawn from it is exceedingly clear, and much heavier then common; and if it be mixed with muddy water, it purifies it and renders it limpid, by precipitating all its impurities to the bottom of the veſſel. This water is employed in making the ngo-kia, which is nothing elſe but a kind of glue procured from the ſkin of a black aſs.

The animal is killed and flayed, and the ſkin is ſteeped for five days in water drawn from this well. At the end of that time, it is taken out to be ſcraped and cleaned; it is afterwards cut into ſmall pieces, which are boiled over a ſlow fire, in the ſame kind of water, until it is reduced to a jelly, which is ſtrained, while warm, through a cloth, to free it from all the groſs matter which could not be melted. When this glue is cool, and has acquired a conſiſtence, it is formed into ſquare cakes, upon which the Chineſe imprint characters and coats of arms, or the ſigns of their ſhops.

This well is the only one of the kind in China; it is always ſhut, and ſealed by the governor of the place with his own ſeal, until the cuſtomary day of making the emperor's glue. This operation generally laſts from the autumnal harveſt till the month of March. During that time, the neighbouring people and merchants treat for the purchaſe of the glue with thoſe who guard the well, and with the people who make it. The latter manufacture as much of it as they can, on their own account, with this difference, that it is not ſo pure, and that they are leſs ſcrupulous in examining whether the aſs be fat, or of a very black colour: however, all the glue made here is as much eſteemed at Peking as that which the mandarins who are on the ſpot tranſmit to court and to their friends.

As this drug is in the greateſt requeſt, and as the quantity of it made at Ngo-hien is not ſufficient to ſupply the whole empire, there are not wanting people who counterfeit it elſewhere, and who manufacture a ſpurious kind from the ſkins of mules, horſes, and camels, and ſometimes even from old boots; it is, however, very eaſy to diſtinguiſh that which is genuine; it has neither a bad ſmell nor a diſagreeable taſte when applied to the mouth; it is brittle and friable, and always of a deep black colour, ſometimes inclining to red. The qualities of the counterfeit kind are entirely different; both its taſte and ſmell are diſagreeable, and it is viſcous and flabby even when made of the ſkin of a hog, which is that which imitates the true kind the beſt.

The Chineſe attribute a great number of virtues to this drug. They aſſure us that it diſſolves phlegm, facilitates the play and elaſticity of the lungs, gives a free reſpiration to thoſe who breathe with difficulty; that it comforts the breaſt, increaſes the blood, ſtops dyſenteries, provokes urine, and ſtrengthens children in the womb. Without warranting the truth of all theſe properties, it appears, at leaſt, certain, by the teſtimony of the miſſionaries, that this drug is ſerviceable in all diſeaſes of the lungs. It is taken with a decoction of ſimples, and ſometimes in powder, but very ſeldom.

NIAGARA, a fort of North America, which was taken from the French in 1759, and ſtill remains in poſſeſſion of the Britiſh government. To the author of the American Geography this ſeems to give great offence; probably becauſe the fort in a manner commands all the interior parts of the continent; is a key to the north-weſtern territories of the United States; and is ſurrounded by the *Six Nations* of Indians, with whom the Engliſh have been long in alliance. It is ſituated on a ſmall peninſula formed by the river Niagara, as it flows into the lake Ontario. About ſix leagues from the fort is the greateſt cataract in the world, know by the name of the *Waterfall of Niagara*. The river at this fall runs from SSE to NNW; and the rock of the fall croſſes it not in a right line, but forms a kind of figure like a hollow ſemicircle or horſe ſhoe. Above the fall, in the middle of the river, is an iſland about 800 or 1000 feet long; the lower end of which is juſt at the perpendicular edge of the fall. On both ſides of this iſland runs all the water that comes from the lakes of Canada; viz. Lake Superior, Lake Miſchigan, Lake Huron, and Lake Erie, which have ſome large rivers that open themſelves into them. Before the water comes to this iſland, it runs but ſlowly compared with its motion afterwards, when it grows the moſt rapid in the world, running with a ſurpriſing ſwiftneſs before it comes to the fall. It is perfectly white, and in many places is thrown high up into the air. The water that runs down on the weſt ſide is more rapid, in greater abundance, and whiter, than that on the eaſt ſide; and ſeems almoſt to outfly an arrow in ſwiftneſs. When you are at the fall, and look up the river, you may ſee that the water is everywhere exceedingly ſteep, almoſt like the ſide of an hill; but when you come to look at the fall itſelf, it is impoſſible to expreſs the amazement it occaſions. The height of it, as meaſured by mathematical inſtruments, is found to be exactly 137 feet; and when the water is come to the bottom, it jumps back to a very great height in the air. The noiſe may be heard at the diſtance of 45 miles, but ſeldom further; nor can it be heard even at Fort Niagara, which is only ſix leagues diſtant, unleſs Lake Ontario is calm. At that fort it is obſerved, that when they hear the noiſe of the fall more loud than ordinary, they are ſure that a north-eaſt wind will follow; which is the more ſurpriſing, as the fort lies ſouth-weſt from the fall. At ſome times the fall makes a much greater noiſe than at others; and this is held for an infallible ſign of approaching rain or other bad weather.

From the place where the water falls there ariſes abundance of vapour like very thick ſmoke, inſomuch that when viewed at a diſtance you would think that the Indians had ſet the foreſts on fire. Theſe vapours riſe high in the air when it is calm, but are diſperſed by the wind when it blows hard. If you go into this vapour or fog, or if the wind blows it on you, it is ſo penetrating, that in a few moments you will be as wet as if you had been under water. Some are of opinion that when birds come flying into this fog or ſmoke of the fall, they drop down and periſh in the water; either becauſe their wings are become wet, or that the noiſe of the fall aſtoniſhes them, and they know not where to go in the darkneſs: but others think that ſeldom or never any bird periſhes there in that manner; becauſe among the abundance of birds found dead below the fall, there are no other ſorts than ſuch as live and ſwim frequently in the water; as ſwans, geeſe, ducks, water hens, teal, and the like. And very often great flocks of them are ſeen going to deſtruction in this manner: they ſwim in the river above the fall, and ſo are carried down lower and lower by the water; and as water fowl commonly take great delight in being carried with the ſtream, they indulge themſelves in enjoying this pleaſure ſo long, till the ſwiftneſs of the water becomes ſo great, that it is no longer poſſible for them to riſe, but they are driven down the precipice and periſh. They are obſerved, when they draw nigh the fall, to endeavour with all their might to take wing and leave the water; but they cannot. In the months of September and October ſuch abundant quantities of dead water fowl are found every morning below the fall, on the ſhore, that the garriſon of the fort for a long time live chiefly upon them. Beſides the fowl, they find alſo ſeveral ſorts of dead fiſh, alſo deer, bears, and other animals which have tried to croſs the water above the fall: the larger animals are generally found broken to pieces. Juſt below, a little way from the fall, the water is not rapid, but goes all in circles, and whirls like a boiling pot; which however does not hinder the Indians going upon it in ſmall canoes a-fiſhing; but a little further, and lower, the other ſmaller falls begin. When you are above the fall, and look down, your head begins to turn; even ſuch as have been here numberleſs times, will ſeldom venture to look down, without at the ſame time keeping faſt hold of ſome tree with one hand.

It was formerly thought impoſſible for any body living to come at the iſland that is in the middle of the fall: but an accident that happened about 50 years ago made it appear otherwiſe. The hiſtory is this: Two Indians of the Six Nations went out from Niagara fort to hunt upon an iſland that is in the middle of the river, or ſtrait, above the great fall, on which there uſed to be abundance of deer. They took ſome French brandy with them from the fort, which they taſted ſeveral times as they were going over the carrying place; and when they were in their canoe, they took now and then a dram, and ſo went along up the ſtrait towards the iſland where they propoſed to hunt; but growing ſleepy, they laid themſelves down in the canoe, which getting looſe drove back with the ſtream, farther and farther down, till it came nigh that iſland that is in the middle of the fall. Here one of them, awakened by the noiſe of the fall, cries out to the other that they were gone: Yet they tried if poſſible to ſave life. This iſland was nigheſt, and with much working they got on ſhore there. At firſt they were glad; but when they had conſidered every thing, they thought themſelves hardly in a better ſtate than if they had gone down the fall, ſince they had now no other choice, than either to throw themſelves down the ſame, or periſh with hunger. But hard neceſſity put them on invention. At the lower end of the iſland the rock is perpendicular, and no water is running there. The iſland has plenty of wood; they went to work then, and made a ladder or ſhrouds of the bark of the lind tree (which is very tough and ſtrong) ſo long till they could with it reach the water below; one end of this bark ladder they tied faſt to a great tree that grew at the ſide of the rock above the fall, and let the other end down to the water. So they went down along their new invented ſtairs, and when they came to the bottom in the middle of the fall they reſted a little; and as the water next below the fall is not rapid, as before mentioned, they threw themſelves out into it, thinking to ſwim on ſhore. We have ſaid before, that one part of the fall is on one ſide of the iſland, the other on the other ſide. Hence it is, that the waters of the two cataracts running againſt each other, turn back againſt the rock that is juſt under the iſland. Therefore, hardly had the Indians begun to ſwim, before the waves of the eddy threw them back with violence againſt the rock from whence they came. They tried it ſeveral times, but at laſt grew weary; and by being often thrown againſt the rock they were much bruiſed, and the ſkin torn off their bodies in many places. So they were obliged to climb up ſtairs again to the iſland, not knowing what to do. After ſome time they perceived Indians on the ſhore, to whom they cried out. Theſe ſaw and pitied them, but gave them little hope or help: yet they made haſte down to the fort, and told the commandant where two of their brothers were. He perſuaded them to try all poſſible means of relieving the two poor Indians; and it was done in the following manner:

The water that runs on the eaſt ſide of this iſland is ſhallow, eſpecially a little above the iſland towards the eaſtern ſhore. The commandant cauſed poles to be made and pointed with iron; two Indians took upon them to walk to this iſland by the help of theſe poles, to ſave the other poor creatures, or periſh themſelves. They took leave of all their friends, as if they were going to death. Each had two ſuch poles in his hands, to ſet to the bottom of the ſtream, to keep them ſteady; and in this manner reached the iſland: and having given poles to the two poor Indians there, they all returned ſafely to the main land. Theſe two Indians (who in the abovementioned manner were firſt brought to this iſland) were nine days on the iſland, and almoſt ready to ſtarve to death. Now ſince the road to this iſland has been found, the Indians go there often to kill deer, which have tried to croſs the river above the fall, and are driven upon it by the ſtream. On the weſt ſide of this iſland are ſome ſmall iſlands or rocks, of no conſequence. The eaſt ſide of the river is almoſt perpendicular, the weſt ſide more ſloping. In former times, a part of the rock at the fall which is on the weſt ſide of the iſland, hung over in ſuch a manner, that the water which fell perpendicularly from it left a vacancy below, ſo that people could go under between the rock and the water; but the prominent part ſome years ſince broke off and fell down. The breadth of the fall, as it runs in a ſemicircle, is reckoned to be about 300 feet. The iſland is in the middle of the fall, and from it the water on each ſide is almoſt the ſame breadth; the breadth of the iſland at its lower end is about 100 feet. Below the fall, in the holes of the rocks, are great plenty of eels, which the Indians and French catch with their hands without any other means. Every day when the ſun ſhines, you ſee here from ten o'clock in the morning to two in the afternoon, below the fall, and under you, where you ſtand at the ſide of the fall, a glorious rainbow, and ſometimes two, one within the other. The more vapours, the brighter and clearer is the rainbow. When the wind carries the vapours from that place, the rainbow is gone, but appears again as ſoon as new vapours come. From the fall to the landing above it, where the canoes from Lake Erie put aſhore (or from the fall to the upper end of the carrying place), is half a mile. Lower the canoes dare not come, leſt they ſhould be obliged to try the fate of the two Indians, and perhaps with leſs ſucceſs. They have often found below the fall pieces of human bodies, perhaps drunken Indians, that have unhappily come down to the fall. The French ſay, that they have often thrown whole great trees into the water above, to ſee them tumble down the fall: they went down with ſurpriſing ſwiftneſs, but could never be ſeen afterwards; whence it was thought there was a bottomleſs deep or abyſs juſt under the fall. The rock of the fall conſiſts of a gray limeſtone.

Having mentioned the *Six Nations* which live on the banks of the Niagara, we ſhall here, in addition to what we have ſaid elſewhere (ſee AMERICA, N° 17.) ſubjoin a few particulars relative to thoſe nations which, as they ſeem not to be well underſtood even in America, are probably ſtill leſs known in Europe. The information which we have to give was communicated to the Royal Society of London by Mr Richard M'Cauſland ſurgeon to the 8th regiment of foot, who, writing from the beſt authority, informs us, that each nation is divided into three tribes, of which the principal are called the *turtle tribe*, the *wolf tribe*, and the *bear tribe*.

Each tribe has two, three, or more chiefs, called *ſachems*; and this diſtinction is always hereditary in the family, but deſcends along the female line: for inſtance, if a chief dies, one of his ſiſter's ſons, or one of his own brothers, will be appointed to ſucceed him. Among theſe no preference is given to proximity or primogeniture; but the ſachem, during his lifetime, pitches upon one whom he ſuppoſes to have more abilities than the reſt; and in this choice he frequently, though not always, conſults the principal men of the tribe. If the ſucceſſor happens to be a child, the offices of the poſt are performed by ſome of his friends until he is of ſufficient age to act himſelf.

Each of theſe poſts of ſachem has a name which is peculiar to it, and which never changes, as it is always adopted by the ſucceſſor: nor does the order of precedency of each of theſe names or titles ever vary. Nevertheleſs, any ſachem, by abilities and activity, may acquire greater power and influence in the nation than thoſe who rank before him in point of precedency; but this is merely temporary, and dies with him.

Each tribe has one or two chief warriors; which dignity is alſo hereditary, and has a peculiar name attached to it.

Theſe are the only titles of diſtinction which are fixed and permanent in the nation; for although any Indian may by ſuperior talents, either as a counſellor or as a warrior, acquire influence in the nation, yet it is not in his power to tranſmit this to his family.

The Indians have alſo their great women as well as their great men, to whoſe opinions they pay great deference; and this diſtinction is alſo hereditary in families. They do not ſit in council with the ſachems, but have ſeparate ones of their own.—When war is declared, the ſachems and great women generally give up the management of public affairs into the hands of the warriors. It may however ſo happen, that a ſachem may at the ſame time be alſo a chief warrior.

Friendſhips ſeem to have been inſtituted with a view towards ſtrengthening the union between the ſeveral nations of the confederacy; and hence friends are called the *ſinews of the Six Nations*. An Indian has therefore generally one or more friends in each nation. Beſides the attachment which ſubſiſts during the lifetime of the two friends, whenever one of them happens to be killed, it is incumbent on the ſurvivor to replace him, by preſenting to his family either a ſcalp, a priſoner, or a belt conſiſting of ſome thouſands of wampum; and this ceremony is performed by every friend of the deceaſed.

The purpoſe and foundation of war parties, therefore, is in general to procure a priſoner or ſcalp to replace the friend or relation of the Indian who is the head of the party. An Indian who wiſhes to replace a friend or relation preſents a belt to his acquaintance; and as many as chooſe to follow him accept this belt, and become his party. After this, it is of no conſequence whether he goes on the expedition or remains at home (as it often happens that he is a child;) he is ſtill conſidered as the head of the party. The belt he preſented to his party is returned fixed to the ſcalp or priſoner, and paſſes along with them to the friends of the perſon he replaces. Hence it happens, that a war party, returning with more ſcalps or priſoners than the original intention of the party required, will often give one of theſe ſupernumerary ſcalps or priſoners to another war party [illegible] meet going out; upon which this party, having fulfilled the purpoſe of their expedition, will ſometimes return without going to war.

NICÆA, (anc. geog.), the metropolis of Bithynia; ſituated on the lake Aſcanius, in a large and fertile plain; in compaſs 16 ſtadia: firſt built by Antigonus, the ſon of Philip, and thence called *Antigonea*; afterwards completed by Lyſimachus, who called it *Nicæa*, after his conſort the daughter of Antipater. According to Stephanus, it was originally a colony of the Bottiæi, a people of Thrace, and called *Ancore*; and afterwards called *Nicæa*. Now *Nice* in Aſia the Leſs*. Famous for the firſt general council.—A ſecond *Nicæa*, (Diodorus Siculus), of Corſica.—A third, of the Hither India, (Arrian); ſituted on the weſt ſide of the Hydaſpes, oppoſite to Buciphale, on the eaſt ſide.—A fourth *Nicæa*, a town of Liguria, at the Maritime Alps, on the eaſt ſide of the river Paulon near its mouth, which runs between the Varus and Nicæa, (Mela). A colony of the Maſſilians, (Stephanus); the laſt town of Italy to the weſt. Now *Nizza* or *Nice*, capital of the county of that name, on the Mediterranean.—A fifth, of Locris, (Strabo); a town near Thermopylæ; one of the keys of that paſs. It ſtood on the Sinus Maliacus.

NICAISE (Claude), a celebrated antiquary in the 17th century, was deſcended of a good family at Dijon, where his brother was proctor-general of the chamber of accounts. Being inclined to the church, he became an eccleſiaſtic, and was made a canon in the holy chapel at Dijon; but devoted himſelf wholly to the ſtudy and knowledge of antique monuments. Having laid a proper foundation of learning at home, he reſigned his canonry, and went to Rome, where he reſided many years; and after his return to France, he held a correſpondence with almoſt all the learned men in Europe. Perhaps there never was a man of letters who had ſo frequent and extenſive a commerce with the learned men of his time as the Abbé Nicaiſe. This correſpondence took up a great part of his time, and hindered him from enriching the public with any large works; but the letters which he wrote himſelf, and thoſe which he received from others, would made a fine and curious *Commercium Epiſtolicum*. He publiſhed a Latin diſſertation *De Nummo Pantheo*; An Explication of an Antique Monument found at Guienne, in the dioceſe of Aach; and A Diſcourſe upon the Form and Figure of the Syrens, which made a great noiſe. In this tract, following the opinion of Huet biſhop of Avranches, he undertook to prove, that they were in reality birds, and not fiſhes or ſea monſters. He tranſlated into French, from the Italian, a piece of Bellori, containing a deſcription of the pictures in the Vatican, to which he added, A Diſſertation upon the Schools of Athens and Parnaſſus, two of Raphael's pictures. He wrote alſo a ſmall tract upon the ancient muſic; and died while he was labouring to preſent the public with the explanation of that antique inſcription, *Minervæ Arpatiæ*, which was found in the village of Velley, where he died in October 1701, aged 78.

NICANDER of Colophon, a celebrated grammarian, poet, and phyſician, who lived about the 160th Olympiad, 140 years before Chriſt, in the reign of Attalus king of Pergamus, who overcame the Gallo-Greeks. He lived many years in Etolia, of which country he wrote a hiſtory. He wrote alſo many other works, of which only two are now remaining. The one is entitled *Theriaca*, deſcribing in verſe the accidents attending wounds made by venomous beaſts, with the proper remedies; the other bearing the title of *Alexipharmaca*, wherein he treats poetically of poiſons and their antidotes. This Nicander is not to be confounded with Nicander of Thyatira.

NICANDRA, in botany: A genus of the monogynia order, belonging to the decandria claſs of plants: and in the natural method ranking under the 30th order, *Contortæ*. The calyx is monophyllous and quadripartite: the corolla is monopetalous, tubulated, and parted into 10 *laciniæ*: the fruit is an oval berry, which is grooved longitudinally, and contains many ſmall angular ſeeds. Of this there is only one ſpecies, the *amara*, a native of Guiana. The leaves and ſtalks are bitter, and uſed by the natives as an emetic and purge.

NICARAGUA, a large river of South America, in a province of the ſame name, whoſe weſtern extremity lies within five miles of the South ſea. It is full of dreadful cataracts, and falls at length into the North ſea.

Nicaragua, a maritime province of South America, in Mexico, bounded on the north by Honduras, on the eaſt by the North ſea, on the ſouth-eaſt by Coſta Rica, and on the ſouth-weſt by the South ſea; being 400 miles in length from eaſt to weſt, and 120 in breadth from north to ſouth. It is one of the moſt fruitful and agreeable provinces in Mexico, and is well watered with lakes and rivers. The air is wholeſome and temperate; and the country produces plenty of ſugar, cochineal, and fine chocolate. One of the lakes is 200 miles in circumference, has an iſland in the middle, and, as ſome ſay, has a tide. Leon de Nicaragua is the capital town.

NICARIA, an iſland of the Archipelago, between Samos and Tine, about 50 miles in circumference. A chain of high mountains runs through the middle, covered with wood, and ſupplies the country with ſprings. The inhabitants are very poor, and of the Greek communion; however, they have a little wheat, and a good deal of barley, figs, honey, and wax.

NICASTRO, an epiſcopal town of Italy, in the kingdom of Naples, and in the Farther Calabria; 16 miles ſouth of Coſenza. E. Long. 15. 59. N. Lat. 39. 15.

NICE, an ancient, handſome, and conſiderable town on the confines of France and Italy, and capital of a county of the ſame name, with a ſtrong citadel, a biſhop's ſee, and a ſenate, which is a kind of a democracy. It has been ſeveral times taken by the French, and laſt of all in 1744, but reſtored after the treaty of Aix-la-Chapelle. It is very agreeably ſituated, four miles from the mouth of the river Var, 83 miles S. by W. of Turin, and 83 eaſt of Aix. E. Long. 6. 22. N. Lat. 43. 42.

Nice, a county and province in the dominions of the duke of Savoy. The inhabitants ſupply Genoa with a great deal of timber for building ſhips; and carry on a great trade in linen cloth, paper, oil, wine, and honey.—"Although the county of Nice be on this

---

* See *Nice*.

Hiſtorical and Pictureſque deſcription of the County of Nice.

this ſide of the mountains, geographers have always conſidered it as a province of Italy, ſince they have given to this beautiful part of Italy the river Var for a weſtern limit, which is alſo the boundary of the county, and flows into the ſea at a league diſtance from the capital. This province is partly covered by the maritime Alps; and is bordered on the eaſt by Piedmont, and the ſtates of Genoa; on the ſouth by the Mediterranean; on the weſt by the Var; and on the north by Dauphiny. Its length is about 20 leagues of the country, which make about 36 Engliſh miles; its breadth is 10 leagues; and its population is about 120,000 ſouls.

"The city of Nice is the capital, and the ſeat of the ſenate, the biſhopric, and government. It has become, within theſe few years, a delightful abode, by the number of ſtrangers who aſſemble there in the winter, either to re-eſtabliſh their health, or to enjoy the mildneſs of the climate, and the beauty of the country, where an unceaſing verdure preſents eternal ſpring.

"The town is ſituated on the ſea-ſhore, and is backed by a rock entirely inſulated, on which was formerly a caſtle, much eſteemed for its poſition; but it was deſtroyed in the year 1706 by Marechal Berwick, the garriſon being too thin to defend the extent of the works. There is a diſtinction between the old and the new town; this laſt is regular, the houſes are well built, and the ſtreets are wide. Its poſition is by the ſide of the ſea, and it is terminated, on one ſide, by a charming terrace, which ſerves for a promenade.

"Any perſon may live peaceably in this province, without fear of being troubled on points of faith, provided he conducts himſelf with decorum. The town has three ſuburbs. 1ſt, That of St John, which conducts to Cimier, about three leagues north from Nice, &c. The promenades this way are very delightful, and may be enjoyed in a carriage. 2d, That of the Poudriere. 3d, That of the *Croix de Marbre*, or Marble Croſs. This ſuburb is new; and the Engliſh almoſt all lodge in it, being very near the town. The houſes are commodious, facing on one ſide the great road which leads to France, and on the other a fine garden, with a proſpect of the ſea. All the houſes are ſeparate from each other: the company hire them for the ſeaſon, *i. e.* from October till May. Apartments may be had from 15 to 250 louis. The proprietors commonly furniſh linen, plate, &c. There are alſo in the town very large and commodious houſes; as well as the new road, which is opened from the town to the port, by cutting that part of the rock which inclined toward the ſea. The ſituation is delightful, and warmeſt in winter, being entirely covered from the north wind, and quite open to the ſouth.

"The company is brilliant at Nice, and the amuſements of the Carnival are, in proportion to the ſize of the town, as lively as in any of the great ones in France. There is always an Italian opera, a concert and maſked ball, alternately; and the company play rather high.

"It is impoſſible to find a happier climate than Nice, both for ſummer and winter. Reaumur's thermometer, in 1781, never fell more than three degrees below the freezing point, and that only for two days; while at Geneva it fell ten: and in the courſe of the winter of 1785 it fell only two degrees; while at Geneva it fell 15. The month of May is rarely ſo fine in France as February at Nice. The ſummer is not ſo hot as might be expected. The thermometer never riſes more than 24 degrees above temperate in the ſhade; and there is always an agreeable ſea breeze from ten in the morning till ſunſet, when the land breeze comes on. There are three chains of graduated mountains, the laſt of which confound their ſummits with the Alps; and to this triple rampart is owing the mild temperature ſo ſenſibly different from that of the neighbouring parts.

"The cultivation of the ground is as rich as can be deſired. There are alternately rows of corn and beans, ſeparated by vines attached to different fruit-trees, the almond and the fig; ſo that the earth being inceſſantly cultivated, and covered with trees, olive, orange, cedar, pomegranate, laurel, and myrtle, cauſes the conſtant appearance of ſpring, and forms a fine contraſt with the ſummits of the Alps, in the back ground, covered with ſnow."

Nice, an ancient town of Aſia, in Natolia, now called *Iſnic*, with a Greek archbiſhop's ſee. It is famous for the general council aſſembled here in 325, which endeavoured to ſuppreſs the doctrines of Arius. It was formerly a large, populous, and well built place, and even now is not inconſiderable. See Isnic.

Nicene Creed, was compoſed and eſtabliſhed, as a proper ſummary of the Chriſtian faith, by the council at Nice in 325, againſt the Arians.—It is alſo called the *Conſtantinopolitan creed*, becauſe it was confirmed, with ſome few alterations, by the council of Conſtantinople in 381. See Creed.

NICEPHORUS (Gregoras), a Greek hiſtorian, was born about the cloſe of the 13th century, and flouriſhed in the 14th, under the emperors Andronicus, John Palæologus, and John Cantacuzenus. He was a great favourite of the elder Andronicus, who made him librarian of the church of Conſtantinople, and ſent him ambaſſador to the prince of Servia. He accompanied this emperor in his misfortunes, and aſſiſted at his death; after which he repaired to the court of the younger Andronicus, where he ſeems to have been well received; and it is certain that, by his influence over the Greeks, that church was prevailed on to refuſe entering into any conference with the legates of Pope John XXII. But in the diſpute which aroſe between Barlaam and Palamos, taking the part of the former, he maintained it zealouſly in the council that was held at Conſtantinople in 1351; for which he was caſt into priſon, and continued there till the return of John Palæologus, who releaſed him; after which he held a diſputation with Palamos, in the preſence of that emperor. He compiled a hiſtory, which in 11 books contains all that paſſed from 1204, when Conſtantinople was taken by the French, to the death of Andronicus Palæologus the younger, in 1341.—The beſt edition of this work is that of the Louvre, in Greek and Latin, in 1702.

Nicephorus (Caliſtus), a Greek hiſtorian, who flouriſhed in the 14th century under the emperor Andronicus Palæologus the elder, wrote an eccleſiaſtical hiſtory in 23 books; 18 of which are ſtill extant, containing the tranſactions of the church from the birth of

Chriſt to the death of the emperor Phocas in 610.—We have nothing elſe but the arguments of the other five books, from the commencement of the reign of the emperor Heraclius, to the end of that of Leo the philoſopher, who died in the year 911. Nicephorus dedicated his hiſtory to Andronicus Palæologus the elder. It was tranſlated into Latin by John Langius; and has gone through ſeveral editions, the beſt of which is that of Paris, in 1630.

Nicephorus (Blemmidas), a prieſt and monk of Mount Athos, flouriſhed in the 13th century. He refuſed the patriarchate of Conſtantinople, being favourable to the Latin church, and more inclined to peace than any of the Greeks of his time. In this ſpirit he compoſed two treatiſes concerning *The Proceſſion of the Holy Ghoſt*: one addreſſed to James patriarch of Bulgaria, and the other to the emperor Theodore Laſcaris. In both theſe he refutes thoſe who maintain, that one cannot ſay the Holy Ghoſt proceeds from the Father and the Son. Theſe two tracts are printed in Greek and Latin by Allatius, who has alſo given us a letter written by Blemmidas on his expelling from the church of her convent Marcheſinos, miſtreſs of the emperor John Ducas. There are ſeveral other pieces of our author in the Vatican library.

NICERON (John Francis), was born at Paris in 1613. Having finiſhed his academical ſtudies, with a ſucceſs which raiſed the greateſt hopes of him, he entered into the order of the Minims, and took the habit in 1632; whereupon, as is uſual, he changed the name given him at his baptiſm for that of Francis, the name of his paternal uncle, who was alſo a Minim, or Franciſcan. The inclination and taſte which he had for mathematics appeared early. He began to apply himſelf to that ſcience in his philoſophical ſtudies, and devoted thereto all the time he could ſpare from his other employments, after he had completed his ſtudies in theology. All the branches of the mathematics, however, did not equally engage his attention; he confined himſelf particularly to optics, and only learned of the reſt as much as was neceſſary for rendering him perfect in this. There remain ſtill, in ſeveral houſes wherein he dwelt, eſpecially at Paris, ſome excellent performances, which diſcover his ſkill in this way, and which make us regret that a longer life did not ſuffer him to carry it to that perfection which he deſired; ſince one cannot help being ſurpriſed that he proceeded ſo far as he did, in the midſt of thoſe occupations and travels by which he was forced from it, during the ſhort ſpace of time which he lived. He hath himſelf obſerved, in the preface to his *Thaumaturgus Opticus*, that he went twice to Rome; and that, on his return home, he was appointed teacher of theology. He was afterwards choſen to accompany Father Francis de la Noue, vicar general of the order, in his viſitation of the convents throughout all France. But the eagerneſs of his paſſion for ſtudy put him upon making the beſt of all the moments he had to ſpare for books; and that wiſe economy furniſhed him with as much as ſatisfied him. Being taken ſick at Aix in Provence, he died there Sept. 22. 1646, aged 33. He was an intimate acquaintance of Des Cartes. A liſt of his writings is inſerted below (A).

Niceron (John Peter), ſo much celebrated on account of his *Memoirs of Men illuſtrious in the Republic of Letters*, was born at Paris, March 11. 1685. He was of an ancient and noble family, who were in very high repute about 1540. He ſtudied with ſucceſs in the Mazarine college at Paris, and afterwards at the college Du Pleſſis. In a ſhort time, reſolving to forſake the world, he conſulted one of his uncles, who belonged to the order of Bernabite Jeſuits. This uncle examined him; and, not diffident of his election, introduced him as a probationer to that ſociety at Paris.—He was received there in 1702, took the habit in 1703, and made his vows in 1704, at the age of 19.

After he had profeſſed himſelf, he was ſent to Montarges, to go through a courſe of philoſophy and theology; thence he went to Loches in Touraine to teach thoſe ſciences. He received the prieſthood at Poitiers in 1708. As he was not arrived at the age to aſſume this order, a diſpenſation, which his uncommon piety had merited, was obtained in his favour. The college of Montarges having recalled him, he was their profeſſor of rhetoric two years, and of philoſophy four.—In ſpite of all theſe avocations, he was humanely attentive to every call and work of charity, and to the inſtruction of his fellow creatures, many of whom heard him deliver out fit rules of conduct for them, not only from the pulpits of moſt of the churches within the province, but even from thoſe of Paris.—In 1716, his ſuperiors invited him to that city, that he might have an opportunity of following, with the more convenience, thoſe ſtudies for which he always had expreſſed the greateſt inclination. He not only underſtood the ancient but the modern languages; a circumſtance of infinite advantage in the compoſition of thoſe works which he has given to the public, and which he carried on with great aſſiduity to the time of his death, which happened, after a ſhort illneſs, July 8. 1738, at the age of 53. His works are, 1. *Le grand Febrifuge*; or, a Diſſertation to prove that common water is the beſt remedy in fevers, and even in the plague, tranſlated from the Engliſh of John Hancock miniſter of St Margaret's, London; in 12mo. This little treatiſe made its appearance, amongſt other pieces relating to this ſubject, in 1720; and was attended with a ſucceſs which carried it through three editions; the laſt came out in 1730, in 2 vols. 12mo, entitled, *A Treatiſe on Common Water*; Paris, printed by Cavelier. 2. *The Voyages of John Ovington to Surat, and divers parts of Aſia and Africa*, containing the hiſtory of the revolution in the kingdom of Golconda, and ſome obſervations upon ſilk worms; Paris, 1725, 2 vols. 12mo. 3. *The Converſion of England to Chriſtianity, compared with its pretended Reformation*, a work tranſlated from

---

(A) Theſe are, 1. *L'Interpretation des chiffres, ou regles pour bien entendre et expliquer facilement toutes ſortes des chiffres ſimples*, &c. 2. *La perſpective curieuſe, ou magie artificielle des effets merveilleux de l'optique, catoprique, et dioptrique.* This is only an eſſay to the following work: 3. *Thaumaturgus opticus; ſive, Admiranda optices, catoptrices, et dioptrices, pars prima*, &c. He intended to add two other parts, but was prevented by death.

the Engliſh; Paris 1729, 8vo. 4. *The Natural Hiſtory of the Earth*, tranſlated from the Engliſh of Mr Woodward, by Monſ. Nogues, doctor in phyſic; with an anſwer to the objections of Dr Carmerarius; containing alſo ſeveral letters written on the ſame ſubject, and a methodical diſtribution of foſſils, tranſlated from the Engliſh by Niceron; Paris 1735, 4to. 5. *Memoirs of Men illuſtrious in the Republic of Letters*, with a critical account of their works; Paris, 12mo. The firſt volume of this great work appeared in 1727; the others were given to the public in ſucceſſion, as far as the 39th, which appeared in 1738. The 40th volume was publiſhed after the death of the author, in 1739.

NICETAS (David), a Greek hiſtorian, a native, as ſome relate, of Paphlagonia, who lived about the end of the 9th century. He wrote *The Life of St Ignatius*, patriarch of Conſtantinople, which was tranſlated into Latin by Frederic Mutius, biſhop of Termoli: he compoſed alſo ſeveral panegyrics in honour of the apoſtles and other ſaints, which are inſerted in the laſt continuation of the *Bibliotheca Patrum* by Combeſis.

Nicetas (ſurnamed Serron), deacon of the church of Conſtantinople, cotemporary with Theophylact in the 11th century, and afterwards biſhop of Heraclea, wrote a *Catena upon the book of Job*, compiled from paſſages of ſeveral of the fathers, which was printed at London in folio, 1637. We have alſo, by the ſame writer, ſeveral *catenæ* upon the Pſalms and Canticles, Baſil 1552; together with a Commentary on the poems of Gregory Nazianzen.

Nicetas (Arhominates), a Greek hiſtorian of the 13th century, called *Coniates*, as being born at Chone, or Coloſſus, in Phrygia. He was employed in ſeveral conſiderable affairs at the court of Conſtantinople; and when that city was taken by the French in 1204, he withdrew, with a young girl taken from the enemy, to Nice in Bithynia, where he married his captive, and died in 1206. He wrote a Hiſtory, or Annals, from the death of Alexius Comnenus in the year 1118, to that of Badouin in 1205; of which work we have a Latin tranſlation by Jerome Wolfius, printed at Baſil in 1557; and it has been inſerted in the body of the Byzantine Hiſtorians, printed in France at the Louvre.

NICHE, in architecture, a hollow ſunk into a wall, for the commodious and agreeable placing of a ſtatue. The word comes from the Italian *nechia*, "ſea-ſhell;" in regard the ſtatue is here encloſed in a ſhell, or perhaps on account of the ſhell wherewith the tops of ſome of them are adorned.

NICHOLS (William), ſon of John Nichols of Donington, in Bucks, was born in 1664. At what ſchool he was educated we have not been informed; but in 1679 he became a commoner of Magdalene Hall, Oxford, whence he afterwards removed to Wadham College, and took the degree of bachelor of arts, Nov. 27. 1683.—In October 1684, he was admitted probationer fellow of Merton College. At the commencement of 1688, he took his maſter's degree; and about the ſame time being admitted into orders, he became chaplain to Ralph earl of Montague, and was in September 1791 preferred to the rectory of Selſey; near Chicheſter, in Suſſex. He was admitted B. D. July 2. 1692; and D. D. Nov. 29. 1695. Though his time was wholly devoted to piety and ſtudy, and though he publiſhed, in Latin and in Engliſh, no fewer than 19 works in defence of Chriſtianity, and the doctrines and worſhip of the church of England, he was ſo totally overlooked, even by thoſe who profeſſed to be patrons of orthodoxy, that towards the cloſe of his life we find him complaining to Robert earl of Oxford, that he was forced on the drudgery of being editor of Mr Selden's books for a little money to buy other books, to enable him to carry on his liturgical labours. He died in the beginning of the year 1712. Of his numerous publications, thoſe which are moſt generally known are, *A Conference with a Theiſt*, in five parts, and *A Comment on the Book of Common Prayer and Adminiſtration of the Sacraments*, &c. A volume of letters in Latin between him and Joblonſki, Oſtervald, and Wetſtein, &c. was preſented, October 28. 1712, by his widow to the archbiſhop of Canterbury; and they are now preſerved among the valuable MSS. at Lambeth, N° 676.

NICHOLLS (Dr Frank), was born in London in the year 1699. His father was a barriſter at law; and both his parents were of good families in Cornwall. After receiving the firſt rudiments of his education at a private ſchool in the country, where his docility and ſweetneſs of temper endeared him equally to his maſter and his ſchool fellows, Frank was in a few years removed to Weſtminſter, and from thence to Oxford, where he was admitted a commoner (or ſojourner) of Exeter college, under the tuition of Mr John Haviland, on March 4. 1714. There he applied himſelf diligently to all the uſual academical ſtudies, but particularly to natural philoſophy and polite literature, of which the fruits were moſt conſpicuous in his ſubſequent lectures on phyſiology. After reading a few books on anatomy, in order to perfect himſelf in the nomenclature of the animal parts then adopted, he engaged in diſſections, and then devoted himſelf to the ſtudy of nature, perfectly free and unbiaſſed by the opinions of others.

On his being choſen reader of anatomy in that univerſity, he employed his utmoſt attention to elevate and illuſtrate a ſcience which had there been long depreſſed and neglected; and by quitting the beaten track of former lecturers, and minutely inveſtigating the texture of every bowel, the nature and order of every veſſel, &c. he gained a high and a juſt reputation. He did not then reſide at Oxford; but, when he had finiſhed his lectures, uſed to repair to London, the place of his abode, where he had determined to ſettle. He had once an intention of fixing in Cornwall, and for a ſhort time practiſed there with great reputation; but being ſoon tired of the fatigues attendant on that profeſſion in the country, he returned to London, bringing back with him a great inſight, acquired by diligent obſervation, into the nature of the miliary fever, which was attended with the moſt ſalutary effects in his ſubſequent practice at London.

About this time he reſolved to viſit the continent, partly with a view of acquiring the knowledge of men, manners, and languages; but chiefly to acquaint himſelf with the opinions of foreign naturaliſts on his favourite ſtudy. At Paris, by converſing freely with the learned, he ſoon recommended himſelf to their notice and eſteem. Winſlow's was the only good ſyſtem of phyſiology at that time known in France, and Morgagni's and Santorini's of Venice in Italy, which Dr Nicholls likewiſe ſoon after viſited. On his return to England, he repeated his phyſiological lectures in London, which were much frequented, not only by ſtudents from both the univerſities, but alſo by many ſurgeons, apothecaries, and others. Soon after, his new and ſucceſsful treatment of the miliary fever, then very prevalent in the ſouthern parts of England, added much to his reputation. In 1725, at a meeting of the Royal Society, he gave his opinion on the nature of *aneuriſms*, in which he diſſented from Dr Freind in his Hiſtory of Phyſic.

At the beginning of the year 1728, he was choſen a fellow of the Royal Society, to which he afterwards communicated the deſcription of an uncommon diſorder (publiſhed in the Tranſactions), viz. a polypus, reſembling a branch of the pulmonary vein (for which Tulpius has ſtrangely miſtaken it), coughed up by an aſthmatic perſon. He alſo made obſervations (in the ſame volume of the Tranſactions) on a treatiſe, by M. Helvetius of Paris, on the Lungs. Towards the end of the year 1729, he took the degree of doctor of phyſic at Oxford. At his return to London, he underwent an examination by the preſident and cenſors of the College of Phyſicians, previous to his being admitted a candidate, which every practitioner muſt be a year before he can apply to be choſen a fellow. Dr. Nicholls was choſen into the college on June 26. 1732; and two years after, being choſen Gulſtonian reader of Pathology, he made the ſtructure of the heart, and the circulation of the blood, the ſubject of his lectures. In 1736, at the requeſt of the preſident, he again read the Gulſtonian lecture; taking for his ſubject thoſe parts of the human body which ſerve for the ſecretion and diſcharge of the urine; and the cauſes, ſymptoms, and cure, of the diſeaſes occaſioned by the ſtone. In 1739, he delivered the anniverſary Harveian oration. In 1743, he married Elizabeth, youngeſt daughter of the celebrated Dr Mead, by whom he had five children, two of whom died young. Two ſons and a daughter ſurvived him. In 1748, Dr Nicholls undertook the office of chirurgical lecturer, beginning with a learned and elegant diſſertation on the *Anima Medica*. About this time, on the death of Dr John Cuningham, one of the elects of the college, Dr Abraham Hall was choſen to ſucceed him, in preference to our author, who was his ſenior, without any apparent reaſon. With a juſt reſentment, he immediately reſigned the office of chirurgical lecturer, and never after attended the meetings of the fellows, except when buſineſs of the utmoſt importance was in agitation.

In 1751, he took ſome revenge in an anonymous pamphlet, entitled "The petition of the Unborn Babes to the Cenſors of the Royal College of Phyſicians of London;" in which Dr Neſbit (*Pocus*), Dr Maule (*Maulus*), Dr Barrowby (*Barebone*), principally, and Sir William Brown, Sir Edward Hulſe, and the Scots incidentally, are the objects of his ſatire.

In 1753, on the death of Sir Hans Sloane, Bart in his 94th year, Dr Nicholls was appointed to ſucceed him as one of the king's phyſicians, and held that office till the death of his royal maſter in 1760, when this moſt ſkilful phyſician was ſuperſeded with ſomething like the offer of a penſion, which he rejected with diſdain.

The cauſes, &c. of the uncommon diſorder of which the late king died, viz. a rupture of the right ventricle of the heart, our author explained in a letter to the earl of Macclesfield, preſident of the Royal Society, which was publiſhed in the Philoſophical Tranſactions Vol. L.

In 1772, to a ſecond edition of his treatiſe *De Anima Medica*, he added a diſſertation *De motu cordis et ſanguinis in homine nato et non nato*, inſcribed to his learned friend and coadjutor the late Dr Lawrence.

Tired at length of London, and alſo deſirous of ſuperintending the education of his ſon, he removed to Oxford, where he had ſpent moſt agreeably ſome years in his youth. But when the ſtudy of the law recalled Mr Nicholls to London, he took a houſe at Epſom, where he paſſed the remainder of his life in a literary retirement, not inattentive to natural philoſophy, eſpecially the cultivation of grain, and the improvement of barren ſoils, and contemplating alſo with admiration the internal nature of plants, as taught by Linnæus.

His conſtitution never was robuſt. In his youth, at Oxford, he was with difficulty recovered from a dangerous fever by the ſkill of Doctors Frampton and Frewen; and afterwards at London he had frequently been afflicted with a catarrh, and an inveterate aſthmatic cough, which, returning with great violence at the beginning of the year 1778, deprived the world of this valuable man on January 7th, in the 80th year of his age.

Dr Lawrence, formerly preſident of the college of phyſicians, who gratefully aſcribed all his phyſiological and medical knowledge to his precepts, and who, while he lived, loved him as a brother, and revered him as a parent, two years after printed, and gave to his friends, a few copies of an elegant Latin Life of Dr Nicholls (with his head prefixed, a ſtriking likeneſs, engraved by Hall from a model of Goſſet, 1779); from which, through the medium of the Gentleman's Magazine, the above particulars are chiefly extracted.

NICIAS, a celebrated painter of Athens, flouriſhed about 322 years before the Chriſtian era; and was univerſally extolled for the great variety and noble choice of his ſubjects, the force and relievo of his figures, his ſkill in the diſtribution of the lights and ſhadows, and his dexterity in repreſenting all ſorts of four-footed animals, beyond any maſter of his time. His moſt celebrated piece was that of Tartarus or Hell, as it is deſcribed by Homer, for which King Ptolemy the ſon of Lagus offered him 60 talents, or 11,250l. which he refuſed, and generouſly preſented it to his own country. He was much eſteemed likewiſe by all his cotemporaries for his excellent talent in ſculpture.

NICKEL, in chemiſtry and mineralogy, a ſubſtance claſſed among the ſemimetals, though ſeveral eminent chemiſts are of opinion that it is a compound; and Mr Bergman, who has made more experiments upon it than any other perſon, conjectures that it is a modification of iron.

It was firſt obtained from an ore called *kupfer-nickel*, ſometimes gray coloured, but often of a reddiſh-yellow; though ſeveral others are now diſcovered. "It had its name (ſays Mr Bergman), and probably ſtill retains it, from this circumſtance, that though it has the appearance of containing copper, not the ſmalleſt particle of that metal can be extracted from it, even by fire." It was firſt mentioned by V. Hiema, in 1694, in a book written in the Swediſh language, concerning the diſcovery of ores and other mineral ſubſtances. It is ſuppoſed by Henckel to be a ſpecies of cobalt, or arſenic alloyed with copper. Cramer claſſes it with the arſenical or cupreous ores; though both they, and all other chemiſts, confeſs that they were never able to extract one particle of copper from it. Mr Cronſtedt, in the years 1751 and 1754, ſhowed by many accurate experiments that it contained a new ſemimetal, or at leaſt that a regulus different from all others was obtainable from its ore. This ore, called *kupfer-nickel*, or falſe copper, as has already been obſerved, is of a coppery lead colour, and almoſt always covered with a greeniſh gray efflореſcence. "It is (ſays Mr Fourcroy) *very common* at Freyberg in Saxony, where it is often mixed with the gray ore of cobalt; but it is diſtinguiſhed from it by its red colour." Mr Bergman, however, complains greatly of the *ſcarcity* of this mineral, ſo that he could hardly procure a quantity ſufficient to make experiments upon. Fourcroy alſo tells us, that "Mr Sage, having treated this ore with ſal-ammoniac, obtained iron, copper, and cobalt, and thinks that it is compoſed of theſe three metallic matters, together with arſenic. It likewiſe contains a ſmall proportion of gold, according to this chemiſt. It is proper to obſerve, that theſe reſults do not agree with thoſe of Mr Bergman; he is ſaid to have operated on the *kupfer-nickel* of Biber, in Heſſe, and of Alemont in Dauphiny. Mr Bergman himſelf, however, informs us, that he undertook his experiments expreſsly with a view to diſcover whether the theory of Mr Sage was juſt; and that he operated moſtly on ſome regulus made by Mr Cronſtedt, and found in the Suabian collection.

"Cronſtedt (ſays Mr Fourcroy) aſſures us, that the metallic matter, called *ſpeiſs* by the Germans, which is collected in the crucibles uſed in the melting of ſmalt, affords nickel. Mr Monnet thinks, that the ſpeiſs of the manufacture of Gengenback, 14 leagues from Straſburg, is true nickel: and as the ore of cobalt made uſe of in that place to make ſmalt is very pure, he concludes, that nickel is neceſſarily a product of cobalt, itſelf. But Mr Beaumé has obtained nickel from almoſt all the ores of cobalt by means of ſulphur; it therefore ſeems, that the ore of cobalt, which is wrought at Gengenback, contains nickel not diſtinguiſhable by the eye, on account of the intimate union of theſe two metallic matters."

"To obtain the regulus of nickel (ſays Mr Bergman, the ore muſt be firſt ſubjected to roaſting; during which a quantity of ſulphur and arſenic, greater or leſs according to the nature of the ore, is expelled; ſo that it ſometimes loſes above half its weight, but frequently not above 0.3. This ore, though long and completely calcined, does not always acquire the ſame colour, but in general becomes greener in proportion as it is more rich. Sometimes (eſpecially if ſuffered to lie at reſt) its upper ſurface is covered with green vegetations, ſomewhat of the form of coral, which are hard and ſonorous. A double or a triple quantity of black flux is to be added to the roaſted powder, and the mixture well fuſed in a forge in an open crucible covered with common ſalt, in the uſual method. The veſſel being broken, a metallic globule is found at the bottom, the weight of which amounts to 0.1, 0.2, or at the moſt to 0.5 of the crude ore. The regulus thus obtained, however, is far from being pure; for although the roaſting be ever ſo violent and long continued, yet a conſiderable quantity of ſulphur, but eſpecially arſenic, ſtill remains concealed, excluſive of cobalt, and a great proportion of iron; which laſt is ſo generally prevalent as to make the regulus magnetic: and this variety of heterogeneous matter is the cauſe why the regulus varies much, not only in reſpect to its fracture, the poliſhed ſurface of which is either ſmooth or lamellated, but alſo in regard to its white colour, which is more or leſs yellow or red.

He has not been able to determine the properties of nickel when perfectly pure, as the continual preſence of iron in ſome reſpect obſcures them: From the calculations which he makes, however, Mr Bergman concludes that the ſpecific gravity of nickel is not leſs than 9.000 at the leaſt. If a ſmall portion of gold enter the compoſition, the greatneſs of the weight might thence be explained; but though this metal is almoſt always abſent, yet 36 parts of it, 48 of iron, and one of copper, were formed by fuſion into a globule, the ſpecific gravity of which was 8.8571, but was little ſoluble in nitrous acid; yet after lying about two hours in the acid, the gold was plainly to be ſeen, and with volatile alkali the menſtruum yielded nothing but a ferruginous brown precipitate, which in the fire put on the appearance of calcined iron.

The ſolutions of nickel in all the acids are green. The vitriolic ſcarcely attacks the regulus unleſs by evaporation to dryneſs. The nitrous acid, by the aſſiſtance of heat, diſſolves both the calx and the regulus: as does likewiſe the marine acid, but ſlowly, and not without the aſſiſtance of heat. Acid of arſenic unites with the calx into a green ſaline maſs; but with the regulus it ſeparates a ſaline powder difficult of fuſion. Fluor acid diſſolves the calx with difficulty, and forms cryſtals of a diluted green colour. Acid of borax ſcarce diſſolves nickel directly, but takes it up by a double elective attraction. Vinegar forms with the calx ſpathoſe cryſtals of an intenſe green colour, which can ſcarce be decompoſed by acid of tartar. The ſaccharine acid converts both regulus and calx into a white powder, not eaſily ſoluble in water. Acid of phoſphorus attracts it but little. The acid of ants by decoction or long digeſtion, attacks the newly precipitated calx; for the ſolution is green and upon evaporation yields cryſtals of a deep green colour, hemiſpherical, formed of filaments diverging from a centre and pellucid. They are not ſoluble in ſpirit of wine, and ſcarcely in water, unleſs it be acidulated. Lemon juice ſeems not to act at all upon nickel. All the acids are deeply tinged by diſſolving nickel; and this property belongs to the firſt regulus as well as that which is moſt highly depurated. Volatile alkali diſſolves it, and the ſolution is of a blue colour; the fixed alkali diſſolves it very ſparingly, and forms a yellow ſolution.

Nickel becomes the more difficult of fuſion, in proportion to its purity, ſo that at laſt it requires nearly as great a heat for this purpoſe as malleable iron. It is eaſily melted with other metals, but its great ſcarcity has prevented this matter from being thoroughly inveſtigated. "It may, however, be obſerved, that the impure regulus cannot be united with ſilver, which muſt be attributed to the cobalt it contains; for when well freed from that metal, it eaſily unites in equal proportions with ſilver, and that without any remarkable diminution of the whiteneſs or ductility of the latter. This mixture, fuſed with borax, tinges it of an hyacinthine colour. Copper unites more ſlowly with depurated nickel, yielding a red and ductile metallic maſs, which tinges borax of a reddiſh hyacinthine colour. It produces only a brittle maſs with tin; in which reſpect it differs from cobalt. It could not be amalgamated with mercury by trituration.

Nickel, when well depurated, does not eaſily part with its phlogiſton, or, in the language of the new nomenclature, receive an acceſſion of carbone; for it only aſſumes a brown colour, and that with great difficulty in the ordinary way of calcination in the aſſay furnace. By means of nitre, however, it is more completely dephlogiſticated, and becomes green. The metallic calx, vitrified with borax, produces an hyacinthine tinge; which yet, if occaſioned by a regulus not well depurated, vaniſhes on continuing the fire, a ſlight blue tinge being produced by the addition of nitre; but a calx of well depurated regulus of nickel forms a permanent colour. The calx of nickel communicates alſo a hyacinthine colour to microcoſmic ſalt; which, by long continued fuſion on charcoal, may indeed be weakened, but can hardly be quite diſcharged. On the addition of nitre it changes to a violet, but becomes again hyacinthine on augmenting the quantity of microcoſmic ſalt. If the calx of nickel be added to ſaturation, the fuſed glaſs aſſumes a blood colour; but on being fuſed, becomes more and more yellow.

Under the article CHEMISTRY, N° 1316, and in the preſent article, we have obſerved, that Mr Bergman conjectures nickel to be only a modification of iron. He examines, however, with great care, the opinion of other authors, who ſuppoſe it to be compoſed of arſenic, copper, cobalt, and iron.—"With reſpect to arſenic (ſays he) we may very ſafely exclude it from the number; as experiments ſhow that it may be entirely expelled. It cannot be doubted but that copper is preſent in ſome ores of nickel, and therefore may eaſily be mixed with the regulus; but the greater number are entirely without it. It is true, that nickel is totally ſoluble in volatile alkali, and that this ſolution is of a blue colour; but if this argument held good, there would be nothing found here but copper; in which caſe very different phenomena would take place from thoſe which are produced by nickel. The blue colour, produced both by copper and nickel, can no more prove their identity than the yellow colour produced both by gold and iron, when diſſolved in aqua regia, can prove the identity of theſe two metals. Nickel and copper agree alſo in this property, that they are both precipitated from acids and from volatile alkali by iron; but a conſiderable difference appears in the manner in which this precipitation is accompliſhed. When a poliſhed piece of iron is put into a ſolution of nickel, a yellow pellicle of the latter will by degrees adhere to it; but this ſoon diſappears on touching, and grows black, unleſs the acid be well ſaturated, or ſufficiently diluted with water. A ſimilar precipitation is obſerved if zinc be made uſe of inſtead of iron; but in ſolution of copper ſo much diluted, that the precipitation on iron may be nearly ſimilar to that of nickel, zinc is immediately covered with a cruſt of the colour of mountain braſs."

An invincible argument that cobalt is no eſſential ingredient in nickel is, that a ſolution of the latter in hepar ſulphuris is precipitated by the former. In the ſame way nickel tinging borax, or the microcoſmic ſalt, in the dry way, is thrown down by the addition of a proper quantity of copper; but this is not the caſe with cobalt. A remarkable difference likewiſe occurs with all the acids. 1. Cobalt tinges all theſe menſtrua of a red colour, yielding cryſtals either of a yellow or bluiſh red. But nickel produces ſolutions and concretions of a fine green; it ſometimes happens, indeed, that the red ſolutions yield greeniſh cryſtals; but this is to be attributed to nickel in ſmall proportion mixed with the cobalt. 2. Cobalt united with the marine acid yields ſympathetic ink, but depurated nickel does not. 3. Cobalt, diſſolved in volatile alkali, affords a red ſolution, but nickel diſſolved in the ſame alkali is blue. 4. Cobalt does not, like nickel, ſeparate, on the addition of arſenical acid, a powder difficult of ſolution. Iron therefore only remains; and indeed, ſays Mr Bergman, there are many and weighty reaſons, which induce us to think that nickel, cobalt, and mangeneſe, are perhaps to be conſidered in no other light than modifications of iron.

1. Unequal portions of phlogiſton, united to the ſame iron, or, according to the new nomenclature, iron containing different proportions of carbone, changes its qualities in a remarkable manner: for inſtance, how very much do the different kinds of iron and ſteel differ? It is then to be obſerved, that nickel, cobalt, and mangeneſe, whatever operations they may be ſubjected to, are ſo far from being deprived of iron, on the contrary, they thereby become more ductile, magnetic, and refractory. Again, The various colours which nickel, cobalt, and mangeneſe exhibit, both by ſolution and by fire, are alſo exhibited by iron. Cobalt and mangeneſe occaſion a red colour in acids, and the latter in glaſs; nickel and mangeneſe occaſion a hyacinthine colour when fuſed with borax; a green is produced in acids by nickel, as alſo by its calx, and by mangeneſe when long and ſtrongly calcined; and it often leaves behind a ſcoria of the ſame colour, if the reduction be performed with a ſaline flux. Laſtly, Cobalt occaſions a blue or rather violet colour in glaſs; and the ſame is true of mangeneſe diſſolved in fixed, and of nickel in volatile, alkali. Iron exhibits all theſe varieties; for the acids form with this metal ſolutions of a green colour as long as it contains a certain quantity of phlogiſton; but in proportion to the diminution of this principle, a yellow, red, or browniſh red, colour is produced. It tinges glaſs in the ſame manner, green, yellow, black, or red. Expoſed to the fire for many hours together with nitre, blue, greeniſh blue, or greeniſh purple flowers, indeed are tranſmitted through the crucible; but an effloreſcence of the ſame kind is produced by nitre alone, which, by long continued fire, penetrates the veſſels, and is decompoſed by the contact of the burning fuel, the alkaline efflo-

Nickel
Nicobar.

reſcences being made blue by the manganeſe, which is always preſent in the circumjacent aſhes; and theſe verge more to a green in proportion as the crocus martis is more copious; beſides, iron itſelf is often found mixed with manganeſe. Hence therefore it appears, that the blue flowers which are expelled from nickel by means of nitre are the produce of manganeſe, as theſe impart to glaſs nothing of the cobalt colour; beſides, in the mineral kingdom, we find the nephritic ſtones, and many others of blue, yellow, red, and green colours, all proceeding from iron alone.

The ores already mentioned, from which nickel has been obtained, are as follow:

1. Mr Rinman aſſerts, that it has been found native in a mine of cobalt in Heſſe. It is very heavy, and of a liver colour or dark red. When pulverized, and roaſted under a muffle, it forms green excreſcences, and ſmokes; but its ſmoke has no particular ſmell, nor can any ſublimate, either ſulphureous or arſenical, be caught. It is ſoluble in acids, and the ſolution is green, but a poliſhed iron plate diſcovers no copper.

2. Aerated nickel is found in form of a calx, and is commonly mixed with the calx of iron; in which caſe it has the name of *nickel-ochre*. This is green, and is found in form of flowers on *kupfer-nickel*. It has been found in Sweden, without any viſible quantity of nickel in its compoſition, in clay which contained much ſilver.

3. *Kupfer-nickel* is of a reddiſh yellow bright colour, as has already been mentioned, and its texture is either uniform, granular, or ſcaly. It is bright when broken, very heavy, and generally covered with a greeniſh efflореſcence. By calcination it loſes much of its ſulphur, and becomes green, forming fungous ramifications. Mr Raſpe informed M. Magellan, that nickel was found mineralized with ſulphurated iron and copper in a mine near Nelſton in Cornwall. The fine grained and ſcaly kinds are found in looſe cobalt mines in the province of Helſingeland in Sweden, where they are of a lighter colour than in other countries, and have often been confounded with the liver-coloured marcaſite.

4. Nickel mineralized with the acid of vitriol is of a beautiful green colour, and may be extracted from the nickel-ochre, or green eſfloreſcences of kupfer-nickel already mentioned.

To the properties of nickel already mentioned, we may add that of its being conſtantly attracted by the magnet, and that not at all in proportion to the quantity of iron it contains; for the more it is purified from this metal, the more magnetical it becomes; and even acquires what iron does not, viz. the properties of a true loadſtone.

NICOBAR ISLANDS, the name of ſeveral iſlands in Aſia, lying at the entrance of the gulf of Bengal. The largeſt of theſe iſlands is about 40 miles long and 15 broad, and the inhabitants are ſaid to be a harmleſs ſort of people, ready to ſupply the ſhips that ſtop there with proviſions. The ſouth end of the great Nicobar is by Captain Ritchie placed in eaſt longitude 94° 23′ 30″; and we collect from Mr Rennel's Memoir, that it is within the 12th degree of north latitude.

Of theſe iſlands very little that can be depended upon is known in Europe. Of the northernmoſt, which is called *Carnicobar*, we have indeed, in the ſecond volume of the Aſiatic Reſearches, ſome intereſting information reſpecting both the produce and natural hiſtory of the country, and the manners of its inhabitants. The author of the memoir is Mr G. Hamilton, who, in his account of this iſland, ſays, "It is low, of a round figure, about 40 miles in circumference, and appears at a diſtance as if entirely covered with trees: however, there are ſeveral well cleared and delightful ſpots upon it. The ſoil is a black kind of clay, and marſhy. It produces in great abundance, and with little care, moſt of the tropical fruits, ſuch as pine-apples, plantains, papayes, cocoa-nuts, and areca-nuts; alſo excellent yams, and a root called *cachu*. The only four-footed animals upon the iſland are, hogs, dogs, large rats, and an animal of the lizard kind, but large, called by the natives *tolonqui*; theſe frequently carry off fowls and chickens. The only kind of poultry are hens, and thoſe not in great plenty. There are abundance of ſnakes of many different kinds, and the inhabitants frequently die of their bites. The timber upon the iſland is of many ſorts, in great plenty, and ſome of it remarkably large, affording excellent materials for building or repairing ſhips.

Nicobar.

"The natives are low in ſtature but very well made, and ſurpriſingly active and ſtrong; they are copper coloured, and their features have a caſt of the Malay, quite the reverſe of elegant. The women in particular are extremely ugly. The men cut their hair ſhort, and the women have their heads ſhaved quite bare, and wear no covering but a ſhort petticoat, made of a ſort of ruſh or dry graſs, which reaches half way down the thigh. This graſs is not interwoven, but hangs round the perſon ſomething like the thatching of a houſe. Such of them as have received preſents of cloth petticoats from the ſhips, commonly tie them round immediately under the arms. The men wear nothing but a narrow ſtrip of cloth about the middle, in which they wrap up their privities ſo tight that there hardly is any appearance of them. The ears of both ſexes are pierced when young; and by ſqueezing into the holes large plugs of wood, or hanging heavy weights of ſhells, they contrive to render them wide, and diſagreeable to look at. They are naturally diſpoſed to be good humoured and gay, and are very fond of ſitting at table with Europeans, where they eat every thing that is ſet before them; and they eat moſt enormouſly. They do not care much for wine, but will drink bumpers of *arack* as long as they can ſee. A great part of their time is ſpent in feaſting and dancing. When a feaſt is held at any village, every one that chooſes goes uninvited, for they are utter ſtrangers to ceremony. At thoſe feaſts they eat immenſe quantities of pork, which is their favourite food. Their hogs are remarkably fat, being fed upon the cocoa nut kernel and ſea water; indeed all their domeſtic animals, fowls, dogs, &c. are fed upon the ſame. They have likewiſe plenty of ſmall ſea fiſh, which they ſtrike very dexterouſly with lances, wading into the ſea about knee deep They are ſure of killing a very ſmall fiſh at 10 or 12 yards diſtance. They eat the pork almoſt raw, giving it only a haſty grill over a quick fire. They roaſt a fowl. by running a piece of wood through it, by way of ſpit, and holding it over a briſk fire until the feathers are burnt off, when it is ready for eating, in their taſte. They never drink water; only cocoa-nut milk and a liquor called *ſoura*, which oozes from the cocoa-nut tree after cutting off the young ſprouts or flowers. This they ſuffer to ferment before it be uſed, and then it is intoxicating; to which quality they add much by their method of drinking it, by ſucking it ſlowly through a ſmall ſtraw. After eating, the young men and women, who are fancifully dreſſed with leaves, go to dancing, and the old people ſurround them ſmoking tobacco and drinking *ſoura*. The dancers, while performing, ſing ſome of their tunes, which are far from wanting harmony, and to which they keep exact time. Of muſical inſtruments they have only one kind, and that the ſimpleſt. It is a hollow bamboo about 2½ feet long and three inches in diameter, along the outſide of which there is ſtretched from end to end a ſingle ſtring made of the threads of a ſplit cane, and the place under the ſtring is hollowed a little to prevent it from touching. This inſtrument is played upon in the ſame manner as a guitar. It is capable of producing but few notes; the performer however makes it ſpeak harmoniouſly, and generally accompanies it with the voice.

" Their houſes are generally built upon the beach, in villages of 15 or 20 houſes each; and each houſe contains a family of 20 perſons and upwards. Theſe habitations are raiſed upon wooden pillars about 10 feet from the ground; they are round, and, having no windows, are like bee-hives, covered with thatch. The entry is through a trap door below, where the family mount by a ladder, which is drawn up at night. This manner of building is intended to ſecure the houſes from being infeſted with ſnakes and rats; and for that purpoſe the pillars are bound round with a ſmooth kind of leaf, which prevents animals from being able to mount; beſides which, each pillar has a broad round flat piece of wood near the top of it, the projecting of which effectually prevents the further progreſs of ſuch vermine as may have paſſed the leaf. The flooring is made with thin ſtrips of bamboos, laid at ſuch diſtances from one another as to leave free admiſſion for light and air; and the inſide is neatly finiſhed and decorated with fiſhing lances, nets, &c.

" The art of making cloth of any kind is quite unknown to the inhabitants of this iſland; what they have is got from the ſhips that come to trade in cocoa-nuts.

" They purchaſe a much larger quantity of cloth than is conſumed upon their own iſland. This is intended for the Choury market. Choury is a ſmall iſland to the ſouthward of theirs, to which a large fleet of their boats ſails every year about the month of November, to exchange cloth for canoes; for they cannot make theſe themſelves. This voyage they perform by the help of the ſun and ſtars, for they know nothing of the compaſs.

" In their diſpoſition there are two remarkable qualities. One is their entire neglect of compliment and ceremony; and the other, their averſion to diſhoneſty. A Carnicobarian travelling to a diſtant village, upon buſineſs or amuſement, paſſes through many towns in his way without ſpeaking to any one; if he is hungry or tired, he goes into the neareſt houſe, and helps himſelf to what he wants, and ſits till he is reſted, without taking the ſmalleſt notice of any of the family unleſs he has buſineſs or news to communicate. Theft or robbery is ſo very rare amongſt them, that a man going out of his houſe never takes away his ladder or ſhuts his door, but leaves it open for any body to enter that pleaſes, without the leaſt apprehenſion of having any thing ſtolen from him.

" Their intercourſe with ſtrangers is ſo frequent, that they have acquired in general the barbarous Portugueſe ſo common over India; their own language has a ſound quite different from moſt others, their words being pronounced with a kind of ſtop, or catch in the throat, at every ſyllable.

" They have no notion of a God, but they believe firmly in the devil, and worſhip him from fear. In every village there is a high pole erected with long ſtrings of ground rattans hanging from it, which, it is ſaid, has the virtue to keep him at a diſtance. When they ſee any ſigns of an approaching ſtorm, they imagine that the devil intends them a viſit, upon which many ſuperſtitious ceremonies are performed. The people of every village march round their own boundaries, and fix up at different diſtances ſmall ſticks ſplit at the top, into which ſplit they put a piece of cocoa-nut, a wiſp of tobacco, and the leaf of a certain plant; whether this is meant as a peace offering to the devil, or a ſcarecrow to frighten him away, does not appear.

" When a man dies, all his liveſtock, cloth, hatchets, fiſhing lances, and in ſhort every moveable thing he poſſeſſed, is buried with him, and his death is mourned by the whole village. In one view this is an excellent cuſtom, ſeeing it prevents all diſputes about the property of the deceaſed amongſt his relations. His wife muſt conform to cuſtom by having a joint cut off from one of her fingers; and if ſhe refuſes this, ſhe muſt ſubmit to have a deep notch cut in one of the pillars of her houſe.

" I was once preſent at the funeral of an old woman. When we went into the houſe which had belonged to the deceaſed, we found it full of her female relations; ſome of them were employed in wrapping up the corpſe in leaves and cloth, and others tearing to pieces all the cloth which had belonged to her. In another houſe hard by, the men of the village with a great many others from the neighbouring towns, were ſitting drinking *ſoura* and ſmoking tobacco. In the mean time two ſtout young fellows were buſy digging a grave in the ſand near the houſe. When the women had done with the corpſe, they ſet up a moſt hideous howl, upon which the people began to aſſemble round the grave, and four men went up into the houſe to bring down the body; in doing this they were much interrupted by a young man, ſon to the deceaſed, who endeavoured with all his might to prevent them, but finding it in vain, he clung round the body, and was carried to the grave along with it: there, after a violent ſtruggle, he was turned away and conducted back to the houſe. The corpſe being now put into the grave, and the laſhings which bound the legs and arms cut, all the live ſtock which had been the property of the deceaſed, conſiſting of about half a dozen hogs, and as many fowls, was killed, and flung in above it; a man then approached with a bunch of leaves ſtuck upon the end of a pole, which he ſwept two or three times gently along the corpſe, and then the grave was filled up. During the ceremony, the women continued to make the moſt horrible vocal concert imaginable: the men ſaid nothing. A few days afterwards, a kind of monument was erected over the grave, with a pole upon it, to which long ſtrips of cloth of different colours were hung.

"Polygamy is not known among them; and their puniſhment of adultery is not leſs ſevere than effectual. They cut, from the man's offending member, a piece of the foreſkin proportioned to the frequent commiſſion or enormity of the crime.

"There ſeems to ſubſiſt among them a perfect equality. A few perſons, from their age, have a little more reſpect paid to them; but there is no appearance of authority one over another. Their ſociety ſeems bound rather by mutual obligations continually conferred and received; the ſimpleſt and beſt of all ties."

It is our wiſh to take all opportunities of laying before our readers every authentic fact which can throw light upon the philoſophy of the human mind. In this narrative of Mr Hamilton's reſpecting the natives of Carnicobar, there is however one circumſtance at which we ſtumble. It is known to the learned, that the philoſophers of Greece and Rome, as well as the magi of Perſia, admitted two ſelf-exiſtent beings, a good and an evil (ſee Polytheism); but we never before read of any people who had no notion of a God, and yet firmly believed in the devil. We could give inſtances of men worſhipping the evil principle from fear, and neglecting the worſhip of the benevolent principle from a perſuaſion that he would do them all the good in his power without being bribed by ſacrifices and oblations; but this is the only inſtance of which we have ever heard, of a people, under the influence of religion, who had *no notion of a God!* As good is at leaſt as apparent in the world as evil, it appears to us ſo very unnatural to admit an *evil* and deny a *good* principle, that we cannot help thinking that Mr Hamilton, from his ignorance of the language of Carnicobar, (which he acknowledges to be different from moſt others), has not a perfect acquaintance with the religious creed of the natives: and that they believe in a good as well as in an evil principle, though they worſhip only the latter, from a perſuaſion, that to adore the former could be of no advantage either to him or to themſelves.

NICODEMUS, a diſciple of Jeſus Chriſt, a Jew by nation, and by ſect a Phariſee (John iii. 1. &c.) The Scripture calls him a ruler of the Jews, and our Saviour gives him the name of a maſter of Iſrael. When our Saviour began to manifeſt himſelf by his miracles at Jeruſalem, at the firſt paſſover that he celebrated there after his baptiſm, Nicodemus made no doubt but that he was the Meſſiah, and came to him by night, that he might learn of him the way of ſalvation. Jeſus told him, that no one could ſee the kingdom of heaven except he ſhould be born again. Nicodemus taking this in the literal ſenſe, made anſwer, "How can a man that is old be born again? Can he enter a ſecond time into his mother's womb?" To which Jeſus replied, "If a man be not born of water and of the ſpirit, he cannot enter into the kingdom of God. That which is born of the fleſh is fleſh, and that which is born of the ſpirit is ſpirit." Nicodemus aſks him, "How can theſe things be?" Jeſus anſwered, "Are you a maſter of Iſrael, and are you ignorant of theſe things? We tell you what we know, and you receive not our teſtimony. If you believe not common things, and which may be called earthly, how will you believe me if I ſpeak to you of heavenly things? Nobody has aſcended into heaven but the Son of God, who came down from thence. And juſt as Moſes lifted up the brazen ſerpent in the wilderneſs, ſo muſt the Son of Man be lifted up on high. For God ſo loved the world that he has given his only Son, ſo that no man who believes in him ſhall periſh, but ſhall have eternal life."

After this converſation Nicodemus became a diſciple of Jeſus Chriſt; and there is no doubt to be made, but he came to hear him as often as our Saviour came to Jeruſalem. It happened on a time, that the prieſts and Phariſees had ſent officers to ſeize Jeſus (John vii. 45, &c.), who returning to them, made their report, that never man ſpoke as he did; to which the Phariſees replied, "Are you alſo of his diſciples? Is there any one of the elders or Phariſees that have believed in him?" Then Nicodemus thought himſelf obliged to make anſwer, ſaying, "Does the law permit us to condemn any one before he is heard?" To which they replied, "Are you alſo a Galilean? Read the Scriptures, and you will find that never any prophet came out of Galilee." After this the council was diſmiſſed. At laſt Nicodemus declared himſelf openly a diſciple of Jeſus Chriſt (*Id.* xix. 39, 40.), when he came with Joſeph of Arimathea to pay the laſt duties to the body of Chriſt, which they took down from the croſs, embalmed, and laid in a ſepulchre.

We are told, that Nicodemus received baptiſm from the diſciples of Chriſt; but it is not mentioned whether before or after the paſſion of our Lord. It is added, that the Jews being informed of this, depoſed him from his dignity of ſenator, excommunicated him, and drove him from Jeruſalem: but that Gamaliel, who was his couſin-german, took him to his country houſe, and maintained him there till his death, when he had him buried honourably near St Stephen. There is ſtill extant an apocryphal goſpel under the name of Nicodemus, which in ſome manuſcripts bears the title of the *Acts of Pilate*.

NICOLAITANS, in church hiſtory, Chriſtian heretics who aſſumed this name from Nicholas of Antioch; who, being a Gentile by birth, firſt embraced Judaiſm and then Chriſtianity; when his zeal and devotion recommended him to the church of Jeruſalem, by whom he was choſen one of the firſt deacons. Many of the primitive writers believe that Nicholas was rather the occaſion than the author of the infamous practices of thoſe who aſſumed his name, who were expreſsly condemned by the Spirit of God himſelf, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives, and made no diſtinction between ordinary meats and thoſe offered to idols. According to Euſebius, they ſubſiſted but a ſhort time; but Tertullian ſays, that they only changed their name, and that their hereſies paſſed into the ſect of the Cainites.

NICOLAS (St), an iſland of the Atlantic ocean, and one of the moſt conſiderable of thoſe of Cape Verde, lying between Santa Lucia and St Jago. It is a triangular figure, and about 75 miles in length. The land is ſtony, mountainous, and barren; but there are a great many goats in a valley inhabited by the Portugueſe. W. Long. 33. 35. N. Lat. 17. 0.

NICOLE (Peter), one of the fineſt writers in Europe, was born at Chartres in 1625, of a conſpicuous family. He adhered to the Janſeniſts; and joined in the compoſition of ſeveral works with Mr Arnauld, whoſe faithful companion he was during the 10 or 12 years of his retirement. He gave a Latin tranſlation of Paſcal's *Provinciales*, and added a commentary to them. One of his fineſt works is his *Eſſais de Morale*. He wrote very ſubtilely againſt the Proteſtants. His treatiſe on the unity of the church is eſteemed a maſterly piece. He died at Paris in 1695, a few days after the publication of his treatiſe concerning the Quietiſts. He was well ſkilled in polite literature. To him is aſcribed a collection of Latin epigrams, and of Greek, Spaniſh, and Italian ſentences, which has borne ſeveral impreſſions, and has a learned preface to it.

NICOLO (St), the moſt conſiderable, ſtrongeſt, and beſt peopled of the iſles of Tremeti in the gulf of Venice, to the eaſt of St Domino, and to the ſouth of Capparata. It has a harbour defended by ſeveral towers; and a fortreſs, in which is an abbey, with a very handſome church. E. Long. 15. 37. N. Lat. 42. 7.

NICOMEDES, the name of ſeveral kings of the ancient Bithynia. See BITHYNIA.

NICOMEDES I. had no ſooner taken poſſeſſion of his father's throne, before Chriſt 270, than, according to the cuſtom which has in all ages been too prevalent among the deſpots of the eaſt, he cauſed two of his brothers to be put to death. The youngeſt, Zibœas, having ſaved himſelf by timely flight, ſeized on the coaſt of Bithynia, which was then known by the names of *Thracia Thyniccia*, and *Thracia Aſiatica*, and there maintained a long war with his brother. Nicomedes being informed that Antiochus Soter, king of Syria, was making great preparations to attack him at the ſame time, called in the Gauls to his aſſiſtance; and on this occaſion that people firſt paſſed into Aſia.—Nicomedes having with their aſſiſtance repulſed Antiochus, overcome his brother, and acquired the poſſeſſion of all his father's dominions, beſtowed upon them that part of Aſia Minor which from them was called *Gallo-Græcia*, and Gallatia. Having now no enemies to contend with, he applied himſelf to the enlarging and adorning of the city of Aſtacus, which he called after his own name *Nicomedia*. He had two wives, and by one of them he was perſuaded to leave his kingdom to her ſon, in preference to his elder brothers; but when or how he died is not certainly known.

NICOMEDES II. the grandſon of the former, began his reign like him, by ſacrificing his brothers to his jealouſy, after having waded to the throne in the blood of Pruſias his father. He aſſumed the name of *Epiphanes*, or "the Illuſtrious," though he performed nothing worthy of this title, or even of notice, during the whole time of his long reign. He was ſucceeded by his ſon——

NICOMEDES III. ſurnamed, by antiphraſis, *Philopater*, becauſe he had murdered his father to get poſſeſſion of his crown. This monarch having entered into alliance with Mithridates the Great king of Pontus, invaded Paphlagonia; and having ſeized on that country, he attempted likewiſe to make himſelf maſter of Cappadocia. This country, however, was at that time ſubject to his powerful ally; who thereupon marching into Bithynia at the head of an army, drove Nicomedes from the throne, and raiſed his brother Socrates to it in his room. The dethroned prince had recourſe to the Romans, who expelled the uſurper, and reſtored him to his hereditary dominions. For this favour they preſſed him, and at length prevailed upon him, contrary to his own inclination, and the opinion of his friends, to make inroads into the territories of Mithridates, with whom Rome wanted a ſubject of diſpute. The king of Pontus bore for ſome time the devaſtations committed by Nicomedes with great patience, that he might not ſeem to be the aggreſſor; but at laſt he routed his army on the banks of the Amnius, drove him a ſecond time from his dominions, and obliged him to ſeek for ſhelter in Paphlagonia, where he led a private life till the time of Sylla, who replaced him on the throne. He was ſucceeded by his ſon——

NICOMEDES IV. who performed nothing which the many writers who flouriſhed in his time have thought worth tranſmitting to poſterity. As he died without iſſue male, he left his kingdom by his laſt will to the Romans, who reduced it to the form of a province. Salluſt, diſagreeing with the ancients, tells us, that Nicomedes left a ſon named *Muſa* or *Myſa*; and introduces Mithridates as complaining of the Romans to Arſaces king of Parthia, for ſeizing on the kingdom of Bithynia, and excluding the ſon of a prince who had on all occaſions ſhown himſelf a ſteady friend to their republic. But this Muſa was the daughter and not the ſon of Nicomedes, as we are told in expreſs terms by Suetonius, Velleius Paterculus, and Appian. All we know of her is, that upon the death of her father ſhe claimed the kingdom of Bithynia for her ſon, as the next male heir to the crown, but without ſucceſs; no motives of juſtice being of ſuch weight with the ambitious Romans as to make them part with a kingdom.

NICOMEDIA (anc. geog.), metropolis of Bithynia, built by Nicomedes the grandfather of Pruſias. Situated on a point of the Sinus Aſtacenus, (Pliny); ſurnamed the *Beautiful*, (Athenæus): the largeſt city of Bithynia, (Pauſanias), who ſays it was formerly called *Aſtacus*; though Pliny diſtinguiſhes Aſtacum and Nicomedia as different cities. Nicomedia was very famous, not only under its own kings, but under the Romans: it was the royal reſidence of Diocleſian, and of Conſtantine while Conſtantinople was building, if we may credit Nicephorus. It is ſtill called *Nicomedia*, at the bottom of a bay of the Propontis in the Hither Aſia. E. Long. 30. 0. N. Lat. 41. 20.

It is a place of conſequence; carries on a trade in ſilk, cotton, glaſs, and earthen ware, and is the ſee of a Greek archbiſhop.

NICOMEDUS, a geometrician, famous on account of the invention of the curve called *conchoid*, which is equally uſeful in reſolving the two problems of doubling the cube and triſecting the angle. It appears that he lived ſoon after Eratoſthenes, for he rallied that philoſopher on the mechaniſm of his meſolabe. Geminus, who lived in the ſecond century before Jeſus Chriſt, has written on the conchoid, though Nicomedus was always eſteemed the inventor of it. Thoſe who place him four or five centuries after Jeſus Chriſt muſt be ignorant of theſe facts, by which we are enabled to aſcertain pretty nearly the time in which he lived.

NICON, a native of Ruſſia, was born in 1613, in a village of the government of Niſhnei Novogorod, of ſuch obſcure parents, that their names and ſtation are not tranſmitted to poſterity. He received at the baptiſmal font the name of *Nikita*, which afterwards, when he became monk, he changed to *Nicon*, the appellation by which he is more generally known. He was educated in the convent of St Macarius, under the care of a monk. From the courſe of his ſtudies, which were almoſt ſolely directed to the Holy Scriptures, and the exhortations of his preceptor, he imbibed at a very early period the ſtrongeſt attachment to a monaſtic life; and was only prevented from following the bent of his mind by the perſuaſions and authority of his father. In conformity, however, to the wiſhes of his family, though contrary to his own inclination, he entered into matrimony; and, as that ſtate precluded him from being admitted into a convent, he was ordained a ſecular prieſt. With his wife he continued ten years, partly in the country and partly at Moſcow, officiating as a pariſh prieſt. The loſs of three children, however, gave him a total diſguſt to the world; in conſequence of which, his wife was perſuaded to take the veil, and he became a monk; his retreat was in an iſland of the White ſea, and a kind of eccleſiaſtical eſtabliſhment was formed, as remarkable for the auſterities of its rules as the ſituation was for its ſolitude. There were about 12 monks, but they all lived in different cells. Such a ſyſtem, combined with the moſt gloomy ideas, occaſioned ſo much cloiſtered pride as tarniſhed his character, when he was afterwards called up to fulfil the duties of a public and exalted ſtation. Our limits do not permit us to be minute in our account of his life, we muſt therefore be contented with barely reciting general facts. Within leſs than the ſpace of five years, Nicon was ſucceſſively created archimandrite, or abbot of the Novoſpatſkoi convent, archbiſhop of Novogorod, and patriarch of Ruſſia. That he was worthy of theſe rapid promotions, few will doubt who are acquainted with his character; for he was poſſeſſed of very extraordinary qualities, ſuch as even his enemies allow and admire. His courage was undaunted, his morals irreproachable, his charity extenſive and exalted, his learning deep and comprehenſive, and his eloquence commanding.—When archbiſhop, he obtained the reſpect of the inhabitants by his unwearied aſſiduity in the diſcharge of his truſt; and conciliated their affections by acts of unbounded charity: Nor was he leſs conſpicuous in the diſcharge of the office of patriarch, to which dignity he was appointed in 1652, in the 39th year of his age.

Nor was he only diſtinguiſhed in his own profeſſion, for he ſhone even as a ſtateſman. At length, however, he fell a victim to popular diſcontents; which misfortune, though he was far from deſerving it, was cer[illegible] the effect of imprudence. He abdicated the offi[illegible] patriarch, which would otherwiſe have been taken from him, in July 1658, and bore his reverſe of fortune with heroic magnanimity: he returned to a cell, and commenced his former auſterities. His innocence, however, could not protect him from further malice: his enemies obtained him to be formally depoſed in 1666. This degradation was followed by impriſonment, which was for ſome time very rigorous, becauſe he, conſcious of his own innocence, refuſed to accept pardon for crimes of which he was not guilty. In 1676, however, he was removed to the convent of St Cyril, and enjoyed perfect liberty.

Nicon ſurvived his depoſition 15 years. In 1681, he requeſted and obtained permiſſion to return to the convent of Jeruſalem, that he might end his days in that favourite ſpot; but he expired upon the road near Yaroſlaf, in the 66th year of his age. His remains were tranſported to that convent, and buried with all the ceremonies uſed at the interment of patriarchs.

NICOPOLI, a town of Turkey in Europe, and in Bulgaria, famous for being the place where the firſt battle was fought between the Turks and Chriſtians in 1396; and where the latter were defeated with the loſs of 20,000 men. E. Long. 25. 33. N. Lat. 43. 46.

NICOSIA, the capital of the iſland of Cyprus, where a Turkiſh baſhaw reſides. It is delightfully ſituated between the mountains of Olympus and a chain of others, and was formerly well fortified by the Venetians; but the works are now in ruins. It is about 31 miles in circumference; and there are plantations of olives, almonds, lemons, oranges, mulberries, and cypreſs trees, interſperſed among the houſes, which give the town a delightful appearance. The church of Sancta Sophia is an old Gothic ſtructure, which the Turks have turned into a moſque, and deſtroyed the ornaments. It is 100 miles weſt of Tripoli, and 160 ſouth-weſt of Aleppo. E. Long. 34. 45. N. Lat. 34. 54.

NICOT (John), lord of Villemain, and maſter of requeſts of the French king's houſehold, was born at Niſmes, and was ſent ambaſſador to Portugal in 1559; whence he brought the plant which, from his name, was called *Nicotiana*, but is now more generally known by the name of *Tobacco*. He died at Paris in 1603. He wrote a French and Latin dictionary in folio: a treatiſe on navigation; and other works.

NICOTIANA, TOBACCO, in botany: a genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 28th order, *Luridæ*. The corolla is funnel-ſhaped, with a plaited limb; the ſtamina inclined; the capſule bivalved and bilocular. There are ſeven ſpecies, of which the moſt remarkable is the *tabaccum*, or common tobacco plant. This was firſt diſcovered in America by the Spaniards about the year 1560, and by them imported into Europe. It had been uſed by the inhabitants of America long before; and was called by thoſe of the iſlands *yoli*, and *petun* by the inhabitants of the continent. It was ſent into Spain from Tabaco, a province of Yucatan, where it was firſt diſcovered, and from whence it takes its common name. Sir Walter Raleigh is generally ſaid to have been the firſt that introduced it into England about the year 1585, and who taught his countrymen how to ſmoke it. Dr Cotton Mather, however, (in his Chriſtian Philoſopher) ſays, that in the above year one Mr Lane carried over ſome of it from Virginia, which was the firſt they had ever been ſeen in Europe. Tobacco is commonly uſed among the oriental nations, though it is uncertain by whom it was introduced among them. Conſiderable quantities of it are cultivated in the Levant, on the coaſts of Greece and the Archipelago, in Italy, and in the iſland of Malta.

There are two varieties of that ſpecies of nicotiana which is cultivated for common uſe, and which are diſtinguiſhed by the names of *Oronokoe*, and *ſweet-ſcented tobacco*. They differ from each other only in the figure of their leaves; thoſe of the former being longer and narrower than the latter. They are tall herbaceous plants, growing erect with fine foliage, and riſing with a ſtrong ſtem from ſix to nine feet high. The ſtalk near the root, is upward of an inch diameter, and ſurrounded with a kind of hairy or velvet clammy ſubſtance, of a yellowiſh green colour. The leaves are rather of a deeper green, and grow alternately at the diſtance of two or three inches from each other. They are oblong, of a ſpear-ſhaped oval, and ſimple; the largeſt about 20 inches long, but decreaſing in ſize as they aſcend, till they come to be only 10 inches long, and about half as broad. The face of the leaves is much corrugated, like thoſe of ſpinage when full ripe. Before they come to maturity, when they are about five or ſix inches long, the leaves are generally of a full green, and rather ſmooth; but as they increaſe in ſize, they become rougher, and acquire a yellowiſh caſt. The ſtem and branches are terminated by large bunches of flowers collected into cluſters, of a delicate red; the edges, when full blown, inclining to a pale purple. They continue in ſucceſſion till the end of the ſummer; when they are ſucceeded by ſeeds of a brown colour, and kidney ſhaped. Theſe are very ſmall, each capſule containing about 1000; and the whole produce of a ſingle plant is reckoned at about 350,000. The ſeeds ripen in the month of September.

Mr Carver informs us, that the Oronokoe, or, as it is called, the *long Virginian tobacco*, is the kind beſt ſuited for bearing the rigour of a northern climate, the ſtrength as well as the ſcent of the leaves being greater than that of the other. The *ſweet-ſcented* ſort flouriſhes moſt in a ſandy ſoil, and in a warm climate, where it greatly exceeds the former in the celerity of its growth; and is likewiſe, as its name intimates, much more mild and pleaſant.

Culture. Tobacco thrives beſt in a warm, kindly, rich ſoil, that is not ſubject to be overrun by weeds. In Virginia, the ſoil in which it thrives beſt is warm, light, and inclining to be ſandy; and therefore, if the plant is to be cultivated in Britain, it ought to be planted in a ſoil as nearly of the ſame kind as poſſible. Other kinds of ſoil might probably be brought to ſuit it, by a mixture of proper manure; but we muſt remember, that whatever manure is made uſe of, muſt be thoroughly incorporated with the ſoil. The beſt ſituation for a tobacco plantation is the ſouthern declivity of a hill rather gradual than abrupt, or a ſpot that is ſheltered from the north winds: but at the ſame time it is neceſſary that the plants enjoy a free air; for without that they will not proſper.

As tobacco is an annual plant, thoſe who intend to cultivate it ought to be as careful as poſſible in the choice of the ſeeds; in which, however, with all their care, they may be ſometimes deceived. The ſeeds are to be ſown about the middle of April, or rather ſooner in a forward ſeaſon, in a bed prepared for this purpoſe of ſuch ſoil as has been already deſcribed, mixed with ſome warm rich manure. In a cold ſpring, hot beds are moſt eligible for this purpoſe, and gardeners imagine that they are always neceſſary: but Mr Carver tells us, that he is convinced, when the weather is not very ſevere, the tobacco ſeeds may be raiſed without doors; and for this purpoſe gives us the following directions.

Treatiſe on the Culture of Tobacco.

"Having ſown the ſeed in the manner above directed, on the leaſt apprehenſion of a froſt after the plants appear, it will be neceſſary to ſpread mats over the beds, a little elevated from the ground by poles laid acroſs, that they may not be cruſhed. Theſe, however, muſt be removed in the morning ſoon after the ſun appears, that they may receive as much benefit as poſſible from its warmth and from the air. In this manner proceed till the leaves have attained about two inches in length and one in breadth; which they will do in about a month after they are ſown, or near the middle of May, when the froſts are uſually at an end. One invariable rule for their being able to bear removal is, when the fourth leaf is ſprouted, and the fifth juſt appears. Then take the opportunity of the firſt rains or gentle ſhowers to tranſplant them into ſuch a ſoil and ſituation as before deſcribed; which muſt be done in the following manner.—The land muſt be ploughed, or dug up with ſpades, and made mellow and light as poſſible. When the plants are to be placed, raiſe with the hoe ſmall hillocks at the diſtance of two feet or a little more from each other, taking care that no hard ſods or lumps are in it; and then juſt indent the middle of each, without drilling holes, as for ſome other plants.

"When your ground is thus prepared, dig in a gentle manner from their native bed ſuch plants as have attained the proper growth for tranſplanting above-mentioned; and drop, as you paſs, one on every hillock. Inſert a plant gently into each centre, preſſing the ſoil around gently with your fingers; and taking the greateſt care, during the operation, that you do not break off any of the leaves, which are at this time exquiſitely tender. If the weather proves dry after they are thus tranſplanted, they muſt be watered with ſoft water, in the ſame manner as is uſually done to coleworts, or plants of a ſimilar kind. But though you now ſeem to have a ſufficient quantity of plants for the ſpace you intend to cultivate, it is yet neceſſary that you continue to attend to your bed of ſeedlings, that you may have enough to ſupply any deficiencies which through accident may ariſe. From this time great care muſt be taken to keep the ground ſoft and free from weeds, by often ſtirring with your hoe the mould round the roots; and to prune off the dead leaves that ſometimes are found near the bottom of the ſtalk.

"The difference of this climate from that in which I have been accuſtomed to obſerve the progreſs of this plant, will not permit me to direct with certainty the time which is moſt proper to take off the top of it, to prevent it from running to ſeed. This knowledge can only be acquired by experience. When it has riſen to the height of more than two feet, it commonly begins to put forth the branches on which the flowers and ſeeds are produced; but as this expanſion, if ſuffered to take place, would drain the nutriment from the leaves, which are the moſt valuable part, and thereby leſſen their ſize and efficacy, it becomes needful at this ſtage to nip off the extremity of the ſtalk to prevent its growing higher. In ſome other climates, the top is commonly cut off when the plant has 15 leaves; but if the tobacco is intended to be a little ſtronger than uſual, this is done when it has only 13; and ſometimes, when it is deſigned to be remarkably powerful, 11 or 12 are only allowed to expand. On the contrary, if the planter is deſirous of having his crop very mild, he ſuffers it to put forth 18 or 20: but in this calculation, the three or four lower leaves next the ground, which do not grow ſo large and fine as the others, are not be reckoned.

"This operation, denominated *topping* the tobacco, is much better performed by the finger and thumb than with any inſtrument; becauſe the graſp of the fingers cloſes the pores of the plant; whereas, when it is done by inſtruments, the juices are in ſome degree exhauſted. Care muſt alſo be taken to nip off the ſprouts that will be continually ſpringing up at the junction of the leaves with the ſtalks. This is termed *ſuccouring*, or *ſuckering*, the tobacco; and ought to be repeated as often as occaſion requires.

"As it is impoſſible to aſcertain the due time for topping the plant, ſo it is equally impoſſible, without experiment, to aſcertain the time it will take to ripen in this country. The apparent ſigns of its maturity are theſe: The leaves, as they approach a ſtate of ripeneſs, become more corrugated or rough; and when fully ripe, appear mottled with yellowiſh ſpots on the raiſed parts; whilſt the cavities retain their uſual green colour. They are at this time alſo thicker than they have before been; and are covered with a downy velvet, like that formerly mentioned, on the ſtalks. If heavy rains happen at this critical period, they will waſh off this excreſcent ſubſtance, and thereby damage the plants. In this caſe, if the froſty nights are not begun, it is proper to let them ſtand a few days longer; when, if the weather be moderate, they will recover this ſubſtance again. But if a froſt unexpectedly happens during the night, they muſt be carefully examined in the morning, before the ſun has any influence upon them; and thoſe which are found to be covered with froſty particles, whether thoroughly ripe or not, muſt be cut up; for though they may not all appear to be arrived at a ſtate of maturity, yet they cannot be far from it, and will differ but little in goodneſs from thoſe that are perfectly ſo."

Tobacco is ſubject to be deſtroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may ſoon be loſt. This animal is of the horned ſpecies, and appears to be peculiar to the tobacco plant; ſo that in many parts of America it is diſtinguiſhed by the name of the *tobacco worm*. In what manner it is firſt produced, or how propagated, is unknown; but it is not diſcernible till the plants have attained about half their height; and then appears to be nearly as large as a gnat. Soon after this it lengthens into a worm; and by degrees increaſes in magnitude to the bigneſs of a man's finger. In ſhape it is regular from its head to its tail, without any diminution at either extremity. It is indented or ribbed round at equal diſtances, nearly a quarter of an inch from each other; and having at every one of theſe diviſions a pair of feet or claws, by which it faſtens itſelf to the plant. Its mouth, like that of the caterpillar, is placed under the fore part of the head. On the top of the head, between the eyes, grows a horn about half an inch long, and greatly reſembling a thorn; the extreme part of which is of a brown colour, a firm texture, and the extremity ſharp pointed. It is eaſily cruſhed; being only, to appearance, a collection of green juice encloſed in a membraneous covering, without the internal parts of an animated being. The colour of its ſkin is in general green, interſperſed with ſeveral ſpots of a yellowiſh white; and the whole covered with a ſhort hair ſcarcely to be diſcerned. Theſe worms are found the moſt predominant during the latter end of July and the beginning of Auguſt; at which time the plants muſt be particularly attended to, and every leaf carefully ſearched. As ſoon as a wound is diſcovered, and it will not be long before it is perceptible, care muſt be taken to deſtroy the cauſe of it, which will be found near it, and from its unſubſtantial texture may eaſily be cruſhed: but the beſt method is to pull it away by the horn, and then cruſh it.

When the tobacco is fit for being gathered, as will appear from an attention to the foregoing directions, on the firſt morning that promiſes a fair day, before the ſun is riſen, take an axe or a long knife, and holding the ſtalk near the top with one hand, ſever it from its root with the other, as low as poſſible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain expoſed to the rays of the ſun throughout the day, or until the leaves, according to the American expreſſion, are entirely cured; that is, till they become limber, and will bend any way without breaking. But if the weather ſhould prove rainy without any intervals of ſunſhine, and the plants appear to be fully ripe, they muſt be houſed immediately. This muſt be done, however, with great care, that the leaves, which are in this ſtate very brittle, may not be broken. They are next to be placed under proper ſhelter, either in a barn or covered hovel, where they cannot be affected by rain or too much air, thinly ſcattered on the floor; and if the ſun does not appear for ſeveral days, they muſt be left to wilt in that manner; but in this caſe the quality of the tobacco will not be quite ſo good.

When the leaves have acquired the above-mentioned flexibility, the plants muſt be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to ſweat. But during this time, when they have lain for a little while, and begin to ferment, it will be neceſſary to turn them;

Nicotiana.

them; bringing thoſe which are in the middle to the ſurface, and placing thoſe which are at the ſurface in the middle. The longer they lie in this ſituation, the darker coloured is the tobacco; and this is termed *ſweating* the tobacco. After they have lain in this manner for three or four days, (for a longer continuance might make the plants turn mouldy,) they may be faſtened together in pairs with cords or wooden pegs, near the bottom of the ſtalk, and hung acroſs a pole, with the leaves ſuſpended in the ſame covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This ſtate may be aſcertained by their appearing of the ſame colour with thoſe imported from America. But this can be done only in wet weather.—The tobacco is exceedingly apt to attract the humidity of the atmoſphere, which gives it a pliability that is abſolutely neceſſary for its preſervation; for if the plants are removed in a very dry ſeaſon, the external parts of the leaves will crumble into duſt, and a conſiderable waſte will enſue.

Cure. As ſoon as the plants are taken down, they muſt again be laid in a heap, and preſſed with heavy logs of wood for about a week; but this climate may poſſibly require a longer time.* While they remain in this ſtate, it will be neceſſary to introduce your hand frequently into the heap, to diſcover whether the heat be not too intenſe; for in large quantities this will ſometimes be the caſe, and conſiderable damage will be occaſioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate glowing warmth, part of the weight by which they are preſſed muſt be taken away; and the cauſe being removed, the effect will ceaſe. This is called the *ſecond* or *laſt ſweating*; and, when completed, which it generally will be about the time juſt mentioned, the leaves muſt be ſtripped from the ſtalks for uſe. Many omit this laſt ſweating; but Mr Carver thinks that it takes away any remaining harſhneſs, and renders the tobacco more mellow. The ſtrength of the ſtalk alſo is diffuſed by it through the leaves, and the whole maſs becomes equally meliorated.—When the leaves are ſtripped from the ſtalks, they are to be tied up in bunches or *hands*, and kept in a cellar or other damp place; though if not handled in dry weather, but only during a rainy ſeaſon, it is of little conſequence in what part of the houſe or barn they are laid up. At this period the tobacco is thoroughly cured, and as proper for manufacturing as that imported from the colonies.

Our author adviſes the tobacco planter, in his firſt trials, not to be too avaricious, but to top his plants before they have gained their utmoſt height: leaving only about the middle quantity of leaves directed before to give it a tolerable degree of ſtrength. For though this, if exceſſive, might be abated during the cure by an increaſe of ſweating, or be remedied the next ſeaſon by ſuffering more leaves to grow, it can never be added; and, without a certain degree of ſtrength, the tobacco will always be taſteleſs and of little value. On the contrary, though it be ever ſo much weakened by ſweating, and thereby rendered mild, yet it will never loſe the aromatic flavour, which accompanied that ſtrength, and which greatly adds to its value. A ſquare yard of land, he tells us, will rear about 500 plants, and allow proper ſpace for their nurture till they are fit for tranſplanting.

Nicotiana.

The following extract, which is copied from a manuſcript of Dr Barham (A), for directing the raiſing, cultivating, and curing tobacco in Jamaica, is perhaps worthy of the attention of thoſe who wiſh to be further acquainted with this ſubject.

"Let the ground or woodland wherein you intend planting tobacco be well burned, as the greater the quantity of wood aſhes the better. The ſpot you intend raiſing your plants on muſt be well ſtrewed with aſhes, laid ſmooth and light: then blow the ſeed from the palm of your hand gently on the bed, and cover it over with palm or plantain leaves.

"When your plants are about four inches high, draw them and plant them out about three feet aſunder; and when they become as high as your knee, cut or pluck off the top; and if there are more than 12 leaves on the plant, take off the overplus, and leave the reſt entire.

"The plant ſhould now be daily attended to in order to deſtroy the caterpillars that are liable to infeſt it; as alſo to take off every ſprout or ſucker that puts out at the joints, in order to throw the whole vegetable nouriſhment into the large leaves.

"When the edges and points of the leaves begin to turn a little yellow, cut down the ſtalks about ten o'clock in the morning, taking the opportunity of a fine day, and be careful the dew is fully off the plant, and do not continue this work after two in the afternoon. As faſt as it is cut let it be carried into your tobacco houſe, which muſt be ſo cloſe as to ſhut out all air, (on this much depends), and hung up on lines tied acroſs, for the purpoſe of drying.

"When the ſtalks begin to turn browniſh, take them off the lines, and put them in a large binn, and lay on them heavy weights for 12 days; then take them out, and ſtrip off the leaves, and put them again into the binn, and let them be well preſſed, and ſo as no air gains admiſſion for a month. Take them out; tie them in bundles about 60 leaves in each, which are called *monococs*; and are ready for ſale. But obſerve to let them always be kept cloſe till you have occaſion to diſpoſe of them.

"Let your curing houſe be well built, and very cloſe and warm; if a boarded building, it will not be amiſs, in a wet ſituation, to cover the whole outſide with thatch and plantain traſh, to keep off the damps; for by this care you preſerve the fine volatile oil in the leaves. Obſerve, no ſmoke is to be made uſe of or admitted into your curing houſe.

Uſe. Since the introduction of tobacco into Europe 1560, various medical properties have been aſcribed to it at different times by Stahl and other German phyſicians;

(A) This gentleman was cotemporary with Sir Hans Sloane. He was a man of great probity, an able phyſician, and a ſkilful naturaliſt. He collected and arranged a number of the plants of Jamaica, which he preſented to Dr Sloane, and made ſeveral communications to the Royal Society.

cians; but the manner in which of late years it has been ſpoken of by the generality of writers on materia medica, has occaſioned it to be almoſt wholly diſmiſſed from modern practice, at leaſt from internal uſe; but this circumſtance has not deterred Dr Fowler, a phyſician of eminence in Staffordſhire, from commencing an inquiry into its medicinal effects; and he has given the reſult of his experiments, which ſeem to be accurately and faithfully related.

That tobacco, under proper regulations, may be adminiſtered internally, not only as a ſafe but as an efficacious remedy, eſpecially as a diuretic, in caſes of dropſy and dyſury, ſeems certain enough. This property, amongſt the vaſt number that have been attributed to it, however, ſeems ſcarcely ever to have been hinted at.

The forms in which Dr Fowler ordered it were either in infuſion, tincture, or pills.

Take of tobacco leaves dried, an ounce; boiling water, one pound: infuſe them for an hour in a cloſe veſſel ſet in a warm place, and ſtrain off about 14 ounces. Then add two ounces of rectified ſpirit of wine.

Take of dried tobacco leaves, an ounce; of rectified ſpirits; Spaniſh white wine, or vinegar, one pint: to be infuſed for four days.

Take of dried tobacco leaves in powder, one drachm; of the conſerve of roſes, enough to make it in a maſs; which is to be divided into 60 pills.

Of the infuſion, or tincture, Dr Fowler gives from ſix to 100 drops twice a day in water, or in a cordial julep, or other proper vehicle, ſufficient to produce the effect in adults; but in irritable habits he ſeldom exceeded 25 drops. To a patient of 10 years old he gave 50 drops; to a child of five years old 20 drops; but to patients under five years old he never ventured to preſcribe it.

The firſt effects of the infuſion is a tranſient heat in the ſtomach and throat, as if the patient had taken a dram. The next general effect in a moderate doſe is diuretic, with or without a ſlight vertigo and giddineſs, and frequently nauſea. In painful caſes, it proves anodyne, and in ſome caſes occaſions drowſineſs and ſleep; in others drowſineſs, with a ſenſe of heat and reſtleſſneſs.

Dr Fowler gave this medicine in 115 caſes: in 93 of which it proved diuretic; in 40 of theſe caſes it occaſioned purging; 79 of theſe patients complained of vertigo. In 52 of the number it excited nauſea; in the two laſt caſes he directs the medicine to be ſuſpended, and the doſes leſſened. Dr Fowler tried it in 30 caſes of dropſy, viz. four of anaſarca, or general dropſy; two of aſcites; and 12 of dropſical ſwellings of the legs, were all cured. In ten other caſes it afforded conſiderable relief; and in three caſes only it was of no uſe. In ten inſtances of dyſury, the infuſion was anodyne and diuretic, thereby abating pain, relaxing the urinary paſſages, and promoting urine.—In dyſuries from gravel, it facilitates the expulſion of calcareous or gritty matter.

Dr Fowler ſpeaks of the uſe of tobacco in injections; an ounce of the infuſion in a pint of water-gruel at a time, and repeated in caſes of obſtinate conſtipation, as the caſe may require. In the *dry bellyach*, in the Weſt Indies, injections of the ſmoke of tobacco have long been employed with the happieſt effects.

After all, the internal uſe of tobacco ſhould be very limited, and can only be ſafe in the hands of a ſkilful and attentive practitioner. Tobacco is ſometimes uſed externally in unguents for deſtroying cutaneous inſects, cleanſing old ulcers, &c. Beaten into a maſh with vinegar or brandy, it has ſometimes proved ſerviceable for removing hard tumours of the hypochondres. An account is given in the Edinburgh Eſſays of two caſes of this kind cured by it. The moſt common uſes of this plant, however, are either as a ſternutatory when taken by way of ſnuff, as a maſticatory by chewing it in the mouth, or as effluvia by ſmoking it; and when taken in moderation, it is not an unhealthful amuſement. Before pipes were invented, it was uſually ſmoked in ſegars, and they are ſtill in uſe among ſome of the ſouthern nations. The method of preparing theſe is at once ſimple and expeditious. A leaf of tobacco being formed into a ſmall twiſted roll, ſomewhat larger than the ſtem of a pipe, and about eight inches long, the ſmoke is conveyed through the winding folds which prevent it from expanding, as through a tube; ſo that one end of it being lighted, and the other applied to the mouth, it is in this form uſed without much inconvenience. But, in proceſs of time, pipes being invented, they were found more commodious vehicles for the ſmoke, and are now in general uſe.

Among all the productions of foreign climes introduced into theſe kingdoms, ſcarce any has been held in higher eſtimation by perſons of every rank than tobacco. In the countries of which it is a native, it is conſidered by the Indians as the moſt valuable offering that can be made to the beings they worſhip. They uſe it in all their civil and religious ceremonies. When once the ſpiral wreaths of its ſmoke aſcend from the feathered pipe of peace, the compact that has been juſt made is conſidered as ſacred and inviolable. Likewiſe, when they addreſs their great Father, or his guardian ſpirits, reſiding, as they believe, in every extraordinary production of nature, they make liberal offerings to them of this valuable plant, not doubting but that they are thus ſecured of protection.

Tobacco is made up into rolls by the inhabitants of the interior parts of America, by means of a machine called a *tobacco wheel*. With this machine they ſpin the leaves after they are cured, into a twiſt of any ſize they think fit; and having folded it into rolls of about 20 pounds each, they lay it by for uſe. In this ſtate it will keep for ſeveral years, and be continually improving, as it always grows milder. The Illinois uſually form it into carrots; which is done by laying a number of leaves, when cured, on each other after the ribs have been taken out, and rolling them round with packthread, till they become cemented together. Theſe rolls commonly meaſure about 18 or 20 inches in length, and nine round in the middle part.

Tobacco forms a very conſiderable article in commerce; for an account of which ſee the articles GLASGOW and VIRGINIA.

NICTITATING MEMBRANE, a thin membrane chiefly found in the bird and fiſh kind, which covers the eyes of theſe animals, ſheltering them from the duſt or too much light; yet is ſo thin and pellucid, that they can ſee pretty well through it.

NIDDUI, in the Jewiſh cuſtoms, is uſed to ſignify "ſeparated or excommunicated." This, according to ſome, was to be underſtood of the leſſer ſort of excommunication in uſe among the Hebrews. He that had incurred it was to withdraw himſelf from his relations, at leaſt to the diſtance of four cubits: it commonly continued a month. If it was not taken off in that time, it might be prolonged for 60 or even 90 days: but if, within this term, the excommunicated perſon did not give ſatisfaction, he fell into the cherem, which was a ſecond ſort of excommunication; and thence into the third ſort, called *ſhammata* or *ſhematta*, the moſt terrible of all. But Selden has proved that there were only two kinds of excommunication, *viz.* the greater and leſs; and that theſe three terms were uſed indifferently.

NIDUS, among naturaliſts, ſignifies a neſt or proper repoſitory for the eggs of birds, inſects, &c. where the young of theſe animals are hatching and nurſed.

NIDIFICATION, a term generally applied to the formation of a bird's neſt, and its hatching or bringing forth its young. See ORNITHOLOGY.

NIECE, a brother's or ſiſter's daughter, which in the civil law is reckoned the third degree of conſanguinity.

NIEMEN, a large river of Poland, which riſes in Lithuania, where it paſſes by Bielica, Grodno, and Konno: it afterwards runs through part of Samogitia and Ducal Pruſſia, where it falls into the lake called the *Curiſch-haff*, by ſeveral mouths, of which the moſt northern is called the *Ruſs*, being the name of a town it paſſes by.

NIENBURGH, a rich and ſtrong town of Germany, in the duchy of Brunſwic-Lunenburg, with a ſtrong caſtle. It carries on a conſiderable trade in corn and wool, and is ſeated in a fertile ſoil on the river Weſer. E. Long. 9. 26. N. Lat. 52. 44.

NIEPER, a large river of Europe, and one of the moſt conſiderable of the North, formerly called the Boriſthenes. Its ſource is in the middle of Muſcovy, running weſt by Smolenſko, as far as Orſa; and then turns ſouth, paſſing by Mohilow, Bohaczo, Kiow, Czyrkaſſy, the fortreſs of Kudak, Deſſau, and Oczakow, falling into the Black ſea; as alſo in its courſe it divides Little Tartary fom Budziac Tartary.

NIESS, a mountain in the environs of Berne in Switzerland. It is the laſt mountain in a high calcareous chain of hills, of which the Stockhorn, the Neuneren, and the Ganteriſh, have been illuſtrated by the botanical labours of the celebrated Haller. Nieſs ſtands on the borders of the lake Thun, and ſeparates the valley of Frutingen from that of Simme. It is very intereſting to the curious traveller, on account of the fine view from its top; and to naturaliſts, becauſe it joins the Alps. Towards its foot, beds of ſlate have been diſcovered; it is of calcareous ſtone higher up; and near its top is found a ſpecies of puddingſtone, filled with ſmall fragments of broken petrifactions.

NIESTER, a large river of Poland, which has its ſource in the Lake Nieſter, in the palatinate of Lemburg, where it paſſes by Halicz. Then it ſeparates Podolia and Oczakow Tartary from Moldavia and Budziac Tartary; and falls into the Black ſea at Belgorod, between the mouths of the Nieper and the Danube.

NIEUHOFF (John de), a Dutch author, was born about the beginning of the laſt century. We are indebted to him for a valuable and curious account, written in Dutch, of his embaſſy from the Dutch Eaſt India Company to the emperor of China. Jean le Carpentier publiſhed an excellent tranſlation of it into French, in folio, Leyden, 1665. This edition is rare, and the book is in great requeſt.

NIEUWENTYT (Bernard), an able philoſopher and learned mathematician, was born at Weſtgraaſdyk, in the year 1654, and became counſellor and burgomaſter of the town of Purmerend, where he was eſteemed for his integrity and learning, and died in 1718. He wrote, in Dutch, 1. An excellent treatiſe, entitled, The Exiſtence of God demonſtrated by the Works of Nature. 2. A Refutation of Spinoza. 3. Some Pieces againſt the Infiniteſimals, &c.

NIGELLA, FENNEL-FLOWER, or *Devil in a Buſh*: A genus of the pentagynia order, belonging to the pentandria claſs of plants. There is no calyx; the petals are five; and five trifid nectaria within the corolla; there are five connected capſules. There are five ſpecies, all of them natives of the warm parts of Europe, and riſing from a foot to a foot and a half high, adorned with blue or yellow flowers. They are propagated by ſeeds, which in a dry and warm ſituation will thrive very well; and the plants ripen ſeeds in this country.

NIGER (C. Peſcennius Juſtus), a celebrated governor in Syria, well known by his valour in the Roman armies while but a private man. At the death of Pertinax he was declared emperor of Rome; and his claims to that elevated ſtation were ſupported by a ſound underſtanding, prudence of mind, moderation, courage, and virtue. He propoſed to imitate the actions of the venerable Antoninus, of Trajan, of Titus, and M. Aurelius. He was remarkable for his fondneſs of ancient diſcipline. He never ſuffered his ſoldiers to drink wine, but obliged them when thirſty to uſe water and vinegar. He forbade the uſe of ſilver or gold utenſils in his camp. All the bakers and cooks were driven away, and the ſoldiers were ordered to live during the expedition they undertook merely upon biſcuits. In his puniſhments Niger was inexorable: he condemned ten of his ſoldiers to be beheaded in the preſence of the army becauſe they had ſtolen and eaten a fowl. The ſentence was heard with groans. The army interfered; and when Niger conſented to diminiſh the puniſhment, for fear of kindling rebellion, he yet ordered the criminals to make each a reſtoration of ten fowls to the perſon whoſe property they had ſtolen. They were beſides ordered not to light a fire the reſt of the campaign, but to live upon cold aliments and to drink nothing but water. Such great qualifications in a general ſeemed to promiſe the reſtoration of ancient diſcipline in the Roman armies; but the death of Niger fruſtrated every hope of reform. Severus, who had alſo been inveſted with the imperial purple, marched againſt him: ſome battles were fought, and Niger was at laſt defeated, A. D. 195. His head was cut off and fixed to a long ſpear, and carried in triumph through the ſtreets of Rome. He reigned about a year.

Niger, a great river of Africa, ſuppoſed to have its origin near that of the Nile; but this is very uncertain. We are aſſured, however, that it is a river of very great extent: eſpecially if we ſuppoſe, according to the opinion of the beſt modern geographers, that it has its ſource in the kingdom of Gorhan, not far from the confines of Upper Ethiopia; for then it will croſs almoſt the whole continent of Africa, where it is wideſt. In its courſe it receives many conſiderable rivers, which ſwell it high enough to be able at all times to carry veſſels of good burden; it ſplits itſelf into ſeveral branches, which uniting again form very large and fertile iſlands, well filled with towns and villages. It paſſes alſo through ſeveral lakes, and has many cataracts. After having run from eaſt to weſt during a prodigious long courſe, it turns at laſt ſhort to the ſouth, at a league and a half diſtance from the weſtern ocean; leaving but a very narrow tract between it and the ſea, into which it opens its way in lat. 15. 55. after having run about 25 leagues from north to ſouth. Its mouth is ſometimes half a league broad; but is ſhut up by a bank of quick ſand, called the *bar of Senegal*, where the water is ſo ſhallow, that it is very difficult and dangerous to paſs over it. The bar is formed by the mud and ſand which the river brings with it during the inundation, and which the ſea continually drives back upon the ſhore. This would effectually exclude all ſhipping, had not the violence of the current, and the weight of the waters, made two openings or channels, which are commonly called the *paſſes of the bar*. The largeſt of theſe is generally not above 150 or 200 fathoms broad, and about 10 feet deep, ſo that none but barks of 40 or 50 tons can get through this channel; the other is ſo narrow and ſhallow, that it is paſſable by canoes only. Theſe channels are not always in the ſame place; for the river, as it is more or leſs ſwelled, or the current more or leſs rapid, open thoſe paſſes ſometimes in one place and ſometimes in another. The bar itſelf alſo frequently ſhifts its place; ſo that the iſland of Senegal is ſometimes four leagues diſtant from it, at other times only two. It is this bar only which hinders ſhips of 400 or 500 tons to go up the river. See Guinea and Negroland.

NIGHT, that part of the natural day during which the ſun is underneath the horizon; or that ſpace wherein it is duſky.

Night was originally divided by the Hebrews and other eaſtern nations into three parts or watches. The Romans, and after them the Jews, divided the night into four parts or watches; the firſt of which began at ſunſet, and laſted till nine at night, according to our way of reckoning; the ſecond laſted till midnight; the third till three in the morning; and the fourth ended at ſunriſe. The ancient Gauls and Germans divided their time not by days but by nights; and the people of Iceland and the Arabs do the ſame at this day. The like is obſerved of the Anglo-Saxons.—The length and ſhortneſs of night or of darkneſs is according to the ſeaſon of the year and poſition of the place; and the cauſes of this variety are now well known. See Astronomy, &c.

Night, in ſcripture language, is uſed for the times of heatheniſh ignorance and profaneneſs (Rom. xiii. 12.); for adverſity and affliction (Iſ. xxi. 12.); and, laſtly, for death (John ix. 4.)

Night-Angling, a method of catching large and ſhy fiſh is the night time. Trout, and many other of the better ſorts of fiſh, are naturally ſhy and fearful; they therefore prey in the night as the ſecureſt time.—The method of taking them on this plan is as follows: The tackle muſt be ſtrong, and need not be ſo fine as for day fiſhing, when every thing is ſeen; the hook muſt be baited with a large earth worm, or a black ſnail, and thrown out into the river; there muſt be no lead to the line, ſo that the bait may not ſink, but be kept drawling along, upon or near the ſurface. Whatever trout is near the place will be brought thither by the motion of the water, and will ſeize the worm or ſnail. The angler will be alarmed by the noiſe which the fiſh makes in riſing, and muſt give him line, and time to ſwallow the hook; then a ſlight touch ſecures him. The beſt and largeſt trouts are found to bite thus in the night; and they riſe moſtly in the ſtill and clear deeps, not in the ſwift and ſhallow currents. Sometimes, though there are fiſh about the place, they will not riſe at the bait: in this caſe the angler muſt put on ſome lead to his line, and ſink it to the bottom.

Night-Mare, or *Incubus*. See Medicine, N° 329.

Night-Walkers, in medicine. See Medicine, N° 329, and Noctambuli.

Night-Walkers, in law, are ſuch perſons as ſleep by day and walk by night, being oftentimes pilferers or diſturbers of the public peace. Conſtables are authorized by the common law to arreſt night-walkers and ſuſpicious perſons, &c. Watchmen may alſo arreſt night-walkers, and hold them until the morning: and it is ſaid, that a private perſon may arreſt any ſuſpicious night-walker, and detain him till he give a good account of himſelf. One may be bound to the good behaviour for being a night-walker; and common night-walkers, or haunters of bawdy-houſes, are to be indicted before juſtices of peace, &c. But it is not held lawful for a conſtable, &c. to take up any woman as a night-walker on bare ſuſpicion only of being of ill fame, unleſs ſhe be guilty of a breach of the peace, or ſome unlawful act, and ought to be found miſdoing.

NIGHTINGALE, in ornithology; a ſpecies of motacilla. See Motacilla, and Plate CCCXV.

The nightingale takes its name from *night*, and the Saxon word *galan*, "to ſing;" expreſſive of the time of its melody. Its ſize and colour has been deſcribed already under Motacilla: to which account we add, that its eyes are remarkably large and piercing; and though it is about equal in ſize to the redſtart, it is longer in body, and more elegantly made.

Mr Hunter found, by diſſection, that the muſcles of the larynx are ſtronger in the nightingale than in any other bird of the ſame ſize.—Sibbald places them in his liſt of Scotch birds; but they certainly are unknown in that part of Great Britain, probably from the ſcarcity and the recent introduction of hedges there. Yet they viſit Sweden, a much more ſevere climate. In England they frequent thick hedges, and low coppices; and generally keep in the middle of the buſh, ſo that they are very rarely ſeen. When the young ones firſt come abroad, and are helpleſs, the old birds make a plaintive and jarring noiſe with a ſort

Nightingale.

of ſnapping as if in menace, purſuing along the hedge the paſſengers.

They begin their ſong in the evening, and continue it the whole night. Theſe their vigils did not paſs unnoticed by the ancients: the ſlumbers of theſe birds were proverbial; and not to reſt as much as the nightingale, expreſſed a very bad ſleeper (A). This was the favourite bird of the Britiſh poet, who omits no opportunity of introducing it, and almoſt conſtantly noting its love of ſolitude and night. How finely does it ſerve to compoſe part of the ſolemn ſcenery of his *Penſeroſo*; when he deſcribes it

> In her ſaddeſt ſweeteſt plight,
> Smoothing the rugged brow of night;
> While *Cynthia* checks her dragon yoke,
> Gently o'er th' accuſtom'd oak.
> Sweet bird, that ſhunn'ſt the noiſe of folly,
> Moſt muſical, moſt melancholy!
> Thee, chauntreſs, oft' the woods among,
> I woo to hear thy evening ſong.

In another place he ſtyles it the *ſolemn bird*; and again ſpeaks of it,

> As the wakeful bird
> Sings darkling, and, in ſhadieſt covert hid,
> Tunes her nocturnal note.

The reader will excuſe a few more quotations from the ſame poet, on the ſame ſubject; the firſt deſcribes the approach of evening, and the retiring of all animals to their repoſe.

> Silence accompanied; for beaſt and bird,
> They to their graſſy couch, theſe to their neſts,
> Were ſlunk; all but the wakeful *nightingale*,
> She all night long her am'rous deſcant ſung.

When Eve paſſed the irkſome night preceding her fall, ſhe, in a dream, imagines herſelf thus reproached with loſing the beauties of the night by indulging too long a repoſe.

> Why ſleep'ſt thou, *Eve?* now is the pleaſant time,
> The cool, the ſilent, ſave where ſilence yields
> To the night warbling bird, that now awake
> Tunes ſweeteſt his love labour'd ſong.

The ſame birds ſing their nuptial ſong, and lull them to reſt. How rapturous are the following lines! how expreſſive of the delicate ſenſibility of our Milton's tender ideas?

> The earth
> Gave ſign of gratulation, and each hill;
> Joyous the birds; freſh gales and gentle airs
> Whiſper'd it to the woods, and from their wings
> Flung roſe, flung odours from the ſpicy ſhrub,
> Diſporting, till the am'rous bird of night
> Sung ſpouſal, and bid haſte the evening ſtar
> On his hill top to light the bridal lamp.
> Theſe, lull'd by *nightingales*, embracing ſlept;
> And on their naked limbs the flow'ry roof
> Shower'd roſes, which the morn repair'd.

Nightingale

Theſe quotations from the beſt judge of melody, we thought due to the ſweeteſt of our feathered chooriſters; and we believe no reader of taſte will think them tedious.

Virgil ſeems to be the only poet among the ancients who hath attended to the circumſtance of this bird's ſinging in the night time.

> *Qualis populeâ mærens* Philomela *ſub umbrâ*
> *Amiſſos queritur fœtus, quos durus arator*
> *Obſervans nido implumes detraxit: at illa*
> *Flet noctem, ramoque ſedens miſerabile carmen*
> *Integrat, et mæſtis late loca queſtibus implet.*
> Georg. IV. l. 511.

> As *Philomel* in poplar ſhades, alone,
> For her loſt offspring pours a mother's moan,
> Which ſome rough ploughman marking for his prey,
> From the warm neſt, unfledg'd, hath dragg'd away;
> Perch'd on a bough, ſhe all night long complains,
> And fills the grove with ſad repeated ſtrains.
> *F. Warton.*

Pliny has deſcribed the warbling notes of this bird with an elegance that beſpeaks an exquiſite ſenſibility of taſte. Lib. X. c. 29.

If the nightingale is kept in a cage, it often begins to ſing about the latter end of November, and continues its ſong more or leſs till June.—A young Canary bird, linnet, ſky lark, or robin (who have never heard any other bird), are ſaid beſt to learn the note of a nightingale.

Mock NIGHTINGALE. See MOTACILLA, ſp. 8.

Virginian NIGHTINGALE, in ornithology, the common, but improper, name of a bird of the groſs-beaked kind, called by authors the *coccothrauſtes Indica criſtata*.

It is a little ſmaller than our blackbird; it has a black ring ſurrounding the eyes and noſtrils; the beak is very large and thick, but not altogether ſo large as in the common groſs-beak; and its head is ornamented with a very high and beautiful creſt, which it moves about very frequently; it is all over of a very fine and lively red, but paler on the head and tail than elſewhere; it is brought to us from Virginia, and is much valued in England for its beauty and delicate manner of ſinging; it is very fond of almonds and the like fruits.

NIGHTSHADE, in botany. See SOLANUM.

Deadly NIGHTSHADE. See ATROPA.—The berries of this plant are of a malignant poiſonous nature; and, being of a ſweet taſte, have frequently proved deſtructive to children. A large glaſs of warm vinegar, taken as ſoon as poſſible after eating the berries, will prevent their bad effects.

Nigidius.

NIGIDIUS FIGULUS (Publius), one of the moſt learned men of ancient Rome, flouriſhed at the ſame time with Cicero. He wrote on various ſubjects; but his pieces appeared ſo refined and difficult that they were not regarded. He aſſiſted Cicero, with great prudence, in defeating Catiline's conſpiracy, and did him many ſervices in the time of his adverſity. He

---

adhered to Pompey in oppoſition to Cæſar; which occaſioned his exile, he dying in baniſhment. Cicero, who had always entertained the higheſt eſteem for him, wrote a beautiful conſolatary letter to him (the 13th of *Lib.* IV. *ad Familiares.*)

NIGRINA, in botany; a genus of the monogynia order, belonging to the petandria claſs of plants. The corolla is funel-ſhaped; the calyx inflated; the ſtigma obtuſe; the capſule bilocular.

NIGRITIA. See NEGROLAND.

NIGUA. See CHEGOE.

NILE, a large and celebrated river of Africa, to which the country of Egypt owes its fertility; and the exploring the ſources of which has, from the remoteſt ages, been accounted an impracticable undertaking. Of late this problem has been ſolved by James Bruce, Eſq; of Kinnaird, in Scotland; who ſpent ſeveral years at the court of Abyſſinia, and by the favour of the emperor and great people of the country was enabled to accompliſh the arduous taſk.

In the account of his travels lately publiſhed, this gentleman has been at particular pains to ſhow, that none of thoſe who undertook this taſk ever ſucceeded in it but himſelf. The inquiry concerning its ſprings, he ſays, began either before hiſtory or tradition, and is by ſome ſuppoſed to be the origin of hieroglyphics. Though Egypt was the country which received the greateſt benefit from this river, it was not there that the inquiries concerning its inundation began: it being probable that every thing relative to the extent and periodical time of that inundation could be accurately ſettled (which could not be done but by a long ſeries of obſervations) before any perſon would venture to build houſes within its reach.

The philoſophers of Meroe, in our author's opinion, were the firſt who undertook to make a number of obſervations ſufficient to determine theſe points; their country being ſo ſituated, that they could perceive every thing relative to the increaſe or decreaſe of the river without any danger from its overflowing. Being much addicted to aſtronomy, it could not long eſcape them, that the heliacal riſing of the dog ſtar was a ſignal for Egypt to prepare for the inundation; without which it was vain to expect any crop. The conection of this celeſtial ſign with the annual riſing of the river would undoubtedly ſoon become a matter of curioſity; and as this could not eaſily be diſcovered, it was natural for an ignorant and ſuperſtitious people to aſcribe the whole to the action of the dog ſtar as a deity. Still however, by thoſe who were more enlightened, the phenomenon would be aſcribed to natural cauſes; and a great ſtep towards the diſcovery of theſe, undoubtedly was that of the ſources of the river itſelf. In the early ages, when travelling into foreign countries was impracticable by private perſons, the inquiry into the ſources of the Nile became an object to the greateſt monarchs. Seſoſtris is ſaid to have preferred the honour of diſcovering them almoſt to all the victories he obtained. Alexander the Great is well known to have had a great curioſity to diſcover theſe fountains. On his arrival at the temple of Jupiter Ammon, he is ſaid to have made inquiry concerning the fountains of the Nile, even before he aſked about his own deſcent from Jupiter. The prieſts are ſaid to have given him proper directions for finding them: and Alexander took the moſt ready means of accompliſhing his purpoſe, by employing natives of Ethiopia to make the ſearch. Theſe diſcoverers, in the opinion of Mr Bruce, miſſed their aim, by reaſon of the turn which the Nile takes to the eaſt in the latitude of 9° where it begins to ſurround the kingdom of Gojam; but which they might imagine to be only a winding of the river ſoon to be compenſated by an equal turn to the weſt. "They therefore (ſays he) continued their journey ſouth till near the line, and never ſaw it more; as they could have no poſſible notion it had turned back behind them, and that they had left it as far north as latitude 9°. They reported then to Alexander what was truth, that they had aſcended the Nile as far ſouth as latitude 9°; where it unexpectedly took its courſe to the eaſt, and was ſeen no more. The river was not known, nor to be heard of near the line, or farther ſouthward, nor was it diminiſhed in ſize, nor had it given any ſymptom that the were near its ſource; they had found the Nile *calentem* (warm), while they expected its riſe among melting ſnows.

Mr Bruce is of opinion that this turn of the Nile to the eaſtward was the occaſion of Alexander's extravagant miſtake, in ſuppoſing that he had diſcovered the fountains of the Nile when he was near the ſource of the Indus; and which he wrote to his mother, though he afterwards cauſed it to be eraſed from his books.

Ptolemy Philadelphus ſucceeded Alexander in his attempts to diſcover the ſource of the Nile; but he likewiſe proving unſucceſsful, the taſk was not undertaken by Ptolemy Euergetes, the moſt powerful of the Greek princes who ſat on the throne of Egypt. "In this (ſays Mr Bruce) he had probably ſucceeded, had he not miſtaken the river itſelf. He ſuppoſed the Siris, now the Tacazze, to be the Nile; and aſcending in the direction of its ſtream, he came to Axum, the capital of Sira and of Ethiopia. But the ſtory he tells of the ſnow which he found knee-deep on the mountains of Samen, makes me queſtion whether he ever croſſed the Siris, or was himſelf an ocular witneſs of what he ſays he obſerved there."

Cæſar had the ſame curioſity with other conquerors to viſit the ſprings of the Nile, though his ſituation did not allow him to make any attempt for that purpoſe. Nero, however, was more active. He ſent two centurions into Ethiopia, with orders to explore the unknown fountains of this river; but they returned without having accompliſhed their errand. They reported, that, after having gone a long way, they came to a king of Ethiopia, who furniſhed them with neceſſaries, and recommendations to ſome other kingdoms adjacent; paſſing which, they came to immenſe lakes, of which nobody knew the end, nor could they ever hope to find it. Their ſtory, however, is by Mr Bruce ſuppoſed to be a fiction; as the Nile forms no lakes throughout its courſe, excepting that of Tzana or Dembea, the limits of which are eaſily perceived.

No other attempt was made by the ancients to diſcover the ſources of this celebrated river; and the matter was looked upon to be an impoſſibility, inſomuch that *caput Nili quærere* became a proverb, denoting the impoſſibility of any undertaking. The firſt who, in more modern ages, made any attempt of this kind was a monk ſent into Abyſſinia in the year 522, by Nonnoſus, ambaſſador from the emperor Juſtin. This monk is called *Coſmas the Hermit*, and likewiſe *Indoplauſtes*, from his ſuppoſed travels into India. He proceeded as far as the city of Axum, but did not viſit that part of the country where the head of the Nile lies; nor, in Mr Bruce's opinion, would it have been practicable for him to do ſo. The diſcovery, however, is ſaid to have been made at laſt by Peter Paez the miſſionary. But the truth of this account is denied by Mr Bruce, for the following reaſons: 1. "No relation of this kind (ſays he) was to be found in three copies of Peter Paez's hiſtory, to which I had acceſs when in Italy, on my return home. One of theſe copies I ſaw at Milan; and, by the intereſt of friends, had an opportunity of peruſing it at my leiſure. The other two were at Bologna and Rome. I ran through them rapidly; attending only to the place where the deſcription ought to have been, and where I did not find it: but having copied the firſt and laſt page of the Milan manuſcript, and comparing them with the two laſt mentioned, I found that all the three were, word for word, the ſame, and none of them contained one ſyllable of the diſcovery of the ſource. 2. Alphonſo Mendez came into Abyſſinia about a year after Paez's death. New and deſirable as that diſcovery muſt have been to himſelf, to the pope, king of Spain, and all his great patrons in Portugal and Italy; though he wrote the hiſtory of the country, and of the particulars concerning the miſſion in great detail and with good judgment, yet he never mentions this journey of Peter Paez, though it probably muſt have been conveyed to Rome and Portugal after his inſpection and under his authority. 3. Balthazar Tellez, a learned Jeſuit, has wrote two volumes in folio, with great candour and impartiality, conſidering the ſpirit of thoſe times; and he declares his work to be compiled from thoſe of Alphonſo Mendez the patriarch, from the two volumes of Peter Paez, as well as from the regular reports made by the individuals of the company in ſome places, and by the provincial letters in others; to all which he had complete acceſs, as alſo to the annual reports of Peter Paez, among the reſt from 1598 to 1622; yet Tellez makes no mention of ſuch a diſcovery, though he is very particular as to the merit of each miſſionary during the long reign of Facilidas, which occupies more than half the two volumes."

The firſt, and indeed the only account of the fountains of the Nile, publiſhed before that of Mr Bruce, was Kircher's; who ſays that he took it from the writings of Peter Paez. The time when the diſcovery is ſaid to have been made was the 21ſt of April 1618; at which ſeaſon the rains are begun, and therefore very unwholeſome; ſo that the Abyſſinian armies are not without extreme neceſſity in the field; between September and February at fartheſt is the time they are abroad from the capital and in action.

"The river (ſays Kircher) at this day, by the Ethiopians, is called *Abavy*; it riſes in the kingdom of Gojam, in a territory called *Sabala*, whoſe inhabitants are called *Agows*. The ſource of the Nile is ſituated in the weſt part of Gojam, in the higheſt part of a valley, which reſembles a great plain on every ſide ſurrounded by high mountains. On the 21ſt of April 1618 being here, together with the king and his army, I aſcended the place, and obſerved every thing with great attention: I diſcovered firſt two round fountains each about four palms in diameter, and ſaw, with the greateſt delight, what neither Cyrus the Perſian, nor Cambyſes, nor Alexander the Great, nor the famous Julius Cæſar, could ever diſcover. The two openings of theſe fountains have no iſſue in the plain on the top of the mountain, but flow from the root it. The ſecond fountain lies about a ſtone-caſt weſt from the former: the inhabitants ſay that this whole mountain is full of water; and add, that the whole plain about the fountain is floating and unſteady, a certain mark that there is water concealed under it; for which reaſon the water does not overflow at the fountain, but forces itſelf with great violence out at the foot of the mountain. The inhabitants together with the emperor, who was then preſent with his army, maintain, that that year it trembled very little on account of the drought; but in other years, that it trembled and overflowed ſo that it could ſcarce be approached without danger. The breadth of the circumference may be about the caſt of a ſling: below the top of this mountain the people live about a league diſtant from the fountain to the weſt; and this place is called *Geeſh*; and the fountain ſeems to be about a cannon ſhot diſtant from Geeſh; moreover the field where the fountain is, is on all ſides difficult of acceſs, except on the north ſide, where it may be aſcended with eaſe."

On this relation Mr Bruce obſerves, that there is no ſuch place as *Sabala*; it ought to have been named *Sacala*, ſignifying the higheſt ridge of land, where the water falls equally down on both ſides, from eaſt and weſt, or from north and ſouth. So the ſharp roofs of our houſes, where the water runs down equally on the oppoſite ſides, are called by the ſame name. Other objections are drawn from the ſituation of places, and from the number and ſituation of the fountains themſelves, every one of which Mr Bruce found by actual menſuration to be different from Kircher's account. The following, however, he looks upon to be deciſive that Paez never was on the ſpot. "He ſays, the field in which the fountains of the Nile are, is of very difficult acceſs; the aſcent to it being very ſteep, excepting on the north, where it is plain and eaſy. Now, if we look at the beginning of this deſcription, we ſhould think it would be the deſcent, not the aſcent, that would be troubleſome; for the fountains were placed in a valley, and people rather *deſcend* into valleys than *aſcend* into them; but ſuppoſing it was a valley in which there was a field upon which there was a mountain, and on the mountain theſe fountains; ſtill, I ſay, that theſe mountains are nearly inacceſſible on the three ſides; but that the moſt difficult of them all is the north, the way we aſcend from the plain of Goutto. From the eaſt, by Sacala, the aſcent is made from the valley of Litchambara, and from the plain of Aſſoa to the ſouth you have the almoſt perpendicular craggy cliff of Geeſh, covered with thorny buſhes, trees, and bamboos, which cover the mouths of the caverns; and on the north you have the mountains of Aformaſha, thick ſet with all ſorts of thorny trees and ſhrubs, eſpecially with the kantuſſa: theſe thickets ar[illegible] over, filled with wild beaſts, eſpecially huge, long-haired baboons, which we frequently met walking upright. Through theſe high and difficult mountains we have only narrow paths, like thoſe of ſheep, made by the goats, or the wild beaſts we are ſpeaking of, which, after we had walked on them for a long ſpace, landed us frequently at the edge of ſome valley or precipice, and forced us to go back again to ſeek a new road. From towards Zeegam to the weſtward, and from the plain where the river winds ſo much, is the only eaſy acceſs to the fountains of the Nile: and they that aſcend to them by this way will not even think that approach too eaſy."

Peter Heiling, a Proteſtant of Lubec, reſided ſeveral years in the country of Gojam, and was even governor of it, but he never made any attempt to diſcover the ſource of the Nile; dedicating himſelf entirely to a ſtudious and ſolitary life. The moſt extraordinary attempt, however, that ever was made to diſcover the ſource of this or any other river, was that of a German nobleman named *Peter Joſeph de Roux*, comte de Deſreval. He had been in the Daniſh navy from the year 1721; and, in 1739, was made rear-admiral. That ſame year he reſigned his commiſſion, and began his attempt to diſcover the ſource of the Nile in Egypt. To this country he took his wife along with him; and had no ſooner reached Cairo, than he quarrelled with a Turkiſh mob on a point of etiquette; which inſtantly brought upon them the janizaries and guards of police, to take them into cuſtody. The counteſs exerted herſelf in an extraordinary manner; and armed only with a pair of ſciſſars, put all the janizaries to flight, and even wounded ſeveral of them; ſo that her huſband was left at liberty to purſue his plan of diſcovery. To accompliſh this, he provided a barge with ſmall cannon, and furniſhed with all neceſſary proviſions for himſelf and his wife, who was ſtill to accompany him. Before he ſet out, however, it was ſuggeſted to him, that, ſuppoſing government might protect him ſo far as to allow his barge to paſs the confines of Egypt ſafely, and to the firſt cataract; ſuppoſing alſo that ſhe was arrived at Ibrim, or Deir, the laſt garriſons depending on Cairo; yet ſtill ſome days journey above the garriſons of Deir and Ibrim began the dreadful deſerts of Nubia; and farther ſouth, at the great cataract of Jan Adel, the Nile falls 20 feet down a perpendicular rock—ſo that here his voyage muſt undoubtedly end. The count, however, flattered himſelf with being able to obtain ſuch aſſiſtance from the garriſons of Ibrim and Deir as would enable him to take the veſſel to pieces, and to carry it above the cataract, where it could again be launched into the river. To facilitate this ſcheme he had even entered into a treaty with ſome of the barbarians named *Kennouſs*, who reſide near the cataract, and employ themſelves in gathering ſena, which abounds in their country. Theſe promiſed to aſſiſt him in this extraordinary adventure; but, luckily for the count, he ſuffered himſelf at laſt to be perſuaded by ſome Venetian merchants at Cairo not to proceed in perſon on ſuch a dangerous and unheard of navigation, but rather to depute Mr Norden, his lieutenant, who was likewiſe to ſerve as his draughtſman, to recoinnoitre the forts of Ibrim and Deir, as well as the cataract of Jan Adel, and renew his treaty with the Kennouſs. This gentleman accordingly embarked upon one of the veſſels common on the Nile, but met with a great many difficulties and diſaſters before he could reach Syene and the firſt cataract; after which having with ſtill greater difficulty reached Ibrim, inſtead of meeting with any encouragement for the count to proceed on his voyage, he was robbed of all he had by the governor of the fort, and narrowly eſcaped with his life; it having been for ſome time determined by him and his ſoldiers, that Mr Norden ſhould be put to death. By theſe difficulties the count was ſo much diſheartened, that he determined to make no more attempts on the Nubian ſide. He now reſolved to enter Abyſſinia by the iſland of Maſuah. With this view he undertook a voyage round the Cape of Good Hope, in order to reach the Red ſea by the ſtraits of Babelmandel: but having begun to uſe his Spaniſh commiſſion, and taken two Engliſh ſhips, he was met by Commodore Barnet, who made prizes of all the veſſels he had with him, and ſent home the count himſelf paſſenger in a Portugueſe ſhip to Liſbon.

Thus Mr Bruce conſiders himſelf as the firſt European who reached the ſources of this river. He informs us that they are in the country of the Agows, as Kircher had ſaid; ſo that the latter muſt either have viſited them himſelf, or have had very good information concerning them. The name of the place through which is the paſſage to the territory of the Agows, is *Abala*; a plain or rather valley, generally about half a mile, and never exceeding a whole mile, in breadth. The mountains which ſurround it are at firſt of an inconſiderable height, covered to the very top with herbage and acacia trees; but as they proceed to the ſouthward they become more rugged and woody.—On the top of theſe mountains are delightful plains, producing excellent paſture. Thoſe to the weſt join a mountain called *Aformaſka*, where, from a direction nearly ſouth-eaſt, they turn ſouth, and encloſe the villages and territory of Sacala, which lie at the foot of them; and ſtill lower, that is, more to the weſtward, is the ſmall village of Geeſh, where the fountains of the Nile are ſituated. Here the mountains are in the form of a creſcent; and along theſe the river takes its courſe. Thoſe which encloſe the eaſt ſide of the plain run parallel to the former in their whole courſe, making part of the mountains of Lechtambara, or at leaſt joining with them, and theſe two, when behind Aformaſka, turn to the ſouth, and then to the ſouth-weſt, taking the ſame form as they do; only making a greater curve, and encloſing them likewiſe in the form of a creſcent, the extremity of which terminates immediately above a ſmall lake named *Gooderoo* in the plain of Aſſoa, below Geeſh, and directly at the fountains of the Nile.

Having paſſed ſeveral conſiderable ſtreams, all of which empty themſelves into the Nile, our traveller found himſelf at laſt obliged to aſcend a very ſteep and rugged mountain, where no other path was to be found but a very narrow one made by the ſheep or goats, and which in ſome places was broken, and full of holes; in others, he was obſtructed with large ſtones, which ſeemed to have remained there ſince the creation. The whole was covered with thick wood; and he was everywhere ſtopped by the kantuffa, as well as by ſeveral other thorny plants, almoſt as troubleſome as that. Having at laſt, however, reached the top, he had a ſight of the Nile immediately below him ; but ſo diminiſhed in ſize, that it now appeared only a brook ſcarce ſufficient to turn a mill. The village of Geeſh is not within ſight of the fountains of the river, though not more than 600 yards diſtant from them. The country about that place terminates in a cliff of about 300 yards high, which reaches down to the plain of Aſſoa, continuing in the ſame degree of elevation till it meets the Nile again about 17 miles to the ſouthward, after having made the circuit of the provinces of Gojam and Damot. In the middle of this cliff is a vaſt cave running ſtraight northward, with many by paths forming a natural labyrinth, of ſufficient bigneſs to contain the inhabitants of the whole village with their cattle. Into this Mr Bruce advanced about 100 yards ; but he did not chooſe to go farther, as the candle he carried with him ſeemed ready to go out ; and the people aſſured him that there was nothing remarkable to be ſeen at the end. The face of this cliff, fronting the ſouth, affords a very pictureſque view from the plain of Aſſoa below ; parts of the houſes appearing at every ſtage through the buſhes and thickets of trees. The mouths of the cavern above mentioned, as well as of ſeveral others which Mr Bruce did not ſee, are hid by almoſt impenetrable fences of the worſt kind of thorn ; nor is there any other communication betwixt the upper part and the houſes but by narrow winding ſheep paths, very difficult to be diſcovered ; all of them being allowed to be overgrown, as a part of the natural defence of the people. The edge of the cliff is covered with lofty and high trees, which ſeem to form a natural fence to prevent people from falling down : and the beauty of the flowers which the Abyſſinian thorns bear, ſeems to make ſome amends for their bad qualities. From the edge of the cliff of Geeſh, above where the village is ſituated, the ground ſlopes with a deſcent due north, till we come to a triangular marſh upwards of 86 yards broad, and 286 from the edge of the cliff, and from a prieſt's houſe where Mr Bruce reſided. On the eaſt, the ground deſcends with a very gentle ſlope from the large village of Sacala, which gives its name to the territory, and is about ſix miles diſtant from the ſource, though to appearance not above two. About the middle of this marſh, and not quite 40 yards from the foot of the mountain of Geeſh, riſes a circular hillock about three feet from the ſurface of the marſh itſelf, though founded apparently much deeper in it. The diameter of this hillock is not quite 12 feet, and it is ſurrounded by a ſhallow trench which collects the water, and ſends it off to the eaſtward. This is firmly built of ſod brought from the ſides, and kept conſtantly in repair by the Agows, who worſhip the river, and perform their religious ceremonies upon this as an altar. In the midſt of it is a circular hole, in the formation or enlargement of which the work of art is evidently diſcernible. It is always kept clear of graſs and aquatic plants, and the water in it is perfectly pure and limpid, but without any ebullition or motion diſcernible on its ſurface. The mouth is ſome parts of an inch leſs than three feet diameter, and at the time our author firſt viſited it (Nov. 5. 1770), the water ſtood about two inches from the brim, nor did it either increaſe or diminiſh during all the time of his reſidence at Geeſh. On putting down the ſhaft of a lance, he found a very feeble reſiſtance at ſix feet four inches, as if from weak ruſhes and graſs ; and, about ſix inches deeper, he found his lance had entered into ſoft earth, but met with no obſtruction from ſtones or gravel : and the ſame was confirmed by uſing a heavy plummet, with a line beſmeared with ſoap.—This is the firſt fountain of the Nile.

The ſecond fountain is ſituated at about ten feet diſtant from the former, a little to the weſt of ſouth ; and is only 11 inches in diameter, but eight feet three inches deep. The third is about 20 feet SSW from the firſt ; the mouth being ſomewhat more than two feet in diameter, and five feet eight inches in depth. Theſe fountains are made uſe of as altars, and from the foot of each iſſues a briſk running rill, which, uniting with the water of the firſt trench, goes off at the eaſt ſide in a ſtream which, our author conjectures, would fill a pipe about two inches diameter. The water of theſe fountains is extremely light and good, and intenſely cold, though expoſed to the ſcorching heat of the ſun, without any ſhelter ; there being no trees nearer than the cliff of Geeſh. The longitude of the principal fountain was found by Mr Bruce to be 36° 55′ 30″ E. from Greenwich. The elevation of the ground, according to his account, muſt be very great, as the barometer ſtood only at 22 Engliſh inches. "Neither (ſays he) did it vary ſenſibly from that height any of the following days I ſtaid at Geeſh ; and thence I inferred, that at the ſources of the Nile I was then more then two miles above the level of the ſea ; a prodigious height, to enjoy a ſky perpetually clear, as alſo a hot ſun never overcaſt for a moment with clouds from riſing to ſetting." In the morning of Nov. 6. the thermometer ſtood at 44°, at noon 96°, and at ſunſet 46°. It was ſenſibly cold at night, and ſtill more ſo about an hour before ſunriſe.

The Nile thus formed by the union of ſtreams from theſe three fountains, runs eaſtward through the marſh for about 30 yards, with very little increaſe of its water, but ſtill diſtinctly viſible, till it is met by the graſſy brink of the land deſcending from Sacala. By this it is turned gradually NE, and then due north ; and in the two miles in which it flows in that direction it receives many ſmall ſtreams from ſprings on each ſide ; ſo that about this diſtance from the fountains it becomes a ſtream capable of turning a common mill. Our traveller was much taken with the beauty of this ſpot. "The ſmall riſing hills about us (ſays he) were all thick covered with verdure, eſpecially with clover the largeſt and fineſt I ever ſaw ; the tops of the heights covered with trees of a prodigious ſize : the ſtream, at the banks of which we were ſitting, was limpid, and pure as the fineſt cryſtal ; the ſod covered thick with a kind of buſhy tree, that ſeemed to affect to grow to no height, but, thick with foliage and young branches, rather to aſſiſt the ſurface of the water ; whilſt it bore, in prodigious quantities, a beautiful yellow flower, not unlike a ſingle roſe of that colour, but without thorns ; and indeed, upon examination, we found that it was not a ſpecies of the roſe, but of the hypericum."

Here Mr Bruce exults greatly in his ſucceſs ; as

[illegible]

having not only ſeen the fountains of the Nile, but the river itſelf running in a ſmall ſtream; ſo that the ancient ſaying of the poet,

Nec licuit populis parvum te Nile videre,

could not be applied to him. Here he *ſtepped* over it, he ſays, more than 50 times, though he had told us, in the preceding page, that it was *three yards* over. From this ford, however, the Nile turns to the weſtward; and, after running over looſe ſtones occaſionally in that direction about four miles farther, there is a ſmall cataract of about ſix feet in height; after which it leaves the mountainous country, and takes its courſe through the plains of Goutto. Here it flows ſo gently that its motion is ſcarcely to be perceived, but turns and winds in its direction more than any river he ever ſaw; forming more than 20 ſharp angular peninſulas in the ſpace of five miles. Here the ſoil is compoſed of a marſhy clay, quite deſtitute of trees, and very difficult to travel through; and where its ſtream receives no conſiderable addition. Iſſuing out from thence, however, it is joined by ſeveral rivulets which fall from the mountains on each ſide, ſo that it becomes a conſiderable ſtream, with high and broken banks covered with old timber trees for three miles. In its courſe it inclines to the north-eaſt, and winds very much, till it receives firſt a ſmall river named *Diwa*, and then another named *Dee-ohha*, or the river Dee. Turning then ſharply to the eaſt, it falls down another cataract, and about three miles below receives the Jemma, a pure and limpid ſtream, not inferior in ſize to itſelf. Proceeding ſtill to the northward, it receives a number of other ſtreams, and at laſt croſſes the ſouthern part of the lake Tzana or Dembea, preſerving the colour of its ſtream during its paſſage, and iſſuing out at the weſt ſide of it in the territory of Dara.

There is a ford, though very deep and dangerous, at the place where the Nile firſt aſſumes the name of a river, after emerging from the lake Dembea: but the ſtream in other places is exceedingly rapid: the banks in the courſe of a few miles become very high, and are covered with the moſt beautiful and variegated verdure that can be conceived. It is now confined by the mountains of Begemder till it reaches Alata, where is the third cataract. This, we are informed by Mr Bruce, is the moſt magnificent ſight he ever beheld; but he thinks that the height has rather been exaggerated by the miſſionaries, who make it 50 feet; and after many attempts to meaſure it, he is of opinion that it is nearly 40 feet high. At the time he viſited it, the river had been pretty much ſwelled by rains, and fell in one ſheet of water, without any interval, for the ſpace of half an Engliſh mile in breadth, with ſuch a noiſe as ſtunned and made him giddy for ſome time. The river, for ſome ſpace both above and below the fall, was covered with a thick miſt, owing to the ſmall particles of the water daſhed up into the air by the violence of the ſhock. The river, though ſwelled beyond its uſual ſize, retained its clearneſs, and fell into a natural baſon of rock; the ſtream appearing to run back againſt the foot of the precipice over which it falls with great violence; forming innumerable eddies, waves, and being in exceſſive commotion, as may eaſily be imagined. Jerome Lobo pretends that he was able to reach the foot of the rock, and ſit under the prodigious arch of water ſpouting over it; but Mr Bruce does not heſitate to pronounce this to be an abſolute falſehood. The noiſe of the cataract, which, he ſays, is like the loudeſt thunder, could not but confound and deſtroy his ſenſe of hearing; while the rapid motion of the water before his eyes would dazzle the ſight, make him giddy, and utterly deprive him of all of his intellectual powers. "It was a moſt magnificent ſight (ſays Mr Bruce), that ages, added to the greateſt length of human life, would not deface or eradicate from my memory: it ſtruck me with a kind of ſtupor, and a total oblivion of where I was, and of every other ſublunary concern."

About half a mile below the cataract, the Nile is confined between two rocks, where it runs in a narrow channel with impetuous velocity and great noiſe. At the village of Alata there is a bridge over it, conſiſting of one arch, and that no more than 25 feet wide. This bridge is ſtrongly fixed into the ſolid rock on both ſides, and ſome part of the parapets ſtill remain. No crocodiles ever come to Alata, nor are any ever ſeen beyond the cataract.

Below this tremendous water-fall the Nile takes a ſouth-eaſt direction, along the weſtern ſide of Begemder and Amhara on the right, encloſing the province of Gojam. It receives a great number of ſtreams from both ſides, and after ſeveral turns takes at laſt a direction almoſt due north, and approaches within 62 miles of its ſource. Notwithſtanding the vaſt increaſe of its waters, however, it is ſtill fordable at ſome ſeaſons of the year; and the Galla croſs it at all times without any difficulty, either by ſwimming, or on goats-ſkins blown up like bladders. It is likewiſe croſſed on ſmall rafts, placed on two ſkins filled with wind; or by twiſting their hands round the tails of the horſes who ſwim over; a method always uſed by the women who follow the Abyſſinian armies, and are obliged to croſs unfordable rivers. In this part of the river crocodiles are met with in great numbers; but the ſuperſtitious people pretend they have charms ſufficiently powerful to defend themſelves againſt their voracity.—The Nile now ſeems to have forced its paſſage through a gap in ſome very high mountains which bound the country of the Ganges, and falls down a cataract of 280 feet high; and immediately below this are two others, both of very conſiderable height. Theſe mountains run a great way to the weſtward, where they are called *Dyre* or *Tegla*, the eaſtern end of them joining the mountains of Kueira, where they have the name of *Fazuclo*. Theſe mountains, our author informs us, are all inhabited by Pagan nations; but the country is leſs known than any other on the African continent. There is plenty of gold waſhed down from the mountains by the torrents in the rainy ſeaſon; which is the fine gold of Sennaar named *Tibbar*.

The Nile, now running cloſe by Sennaar in a direction nearly north and ſouth, makes afterwards a ſharp turn to the eaſt; affording a pleaſant view in the fair ſeaſon, when it is brim-full, and indeed the only ornament of that bare and inhoſpitable country. Leaving Sennaar, it paſſes by many large towns inhabited by Arabs, all of them of a white complexion; then paſſing Gerri, and turning to the north-eaſt, it joins the Tacazze, paſſing, during its courſe through this country,

try a large and populous town named *Chendi*, probably the Candace of the ancients. Here Mr Bruce ſuppoſes the ancient iſland or peninſula of Meroe to have been ſituated. Having at length received the great river Atbara, the Aſtaboras of the ancients, it turns directly north for about two degrees; then making a very unexpected turn weſt by ſouth for more than two degrees in longitude, and winding very little, it arrives at Korti, the firſt town in Barabra, or kingdom of Dongola. From Korti it runs almoſt ſouthweſt till it paſſes Dongola, called alſo *Beja*, the capital of Barabra; after which it comes to Moſcho, a conſiderable town and place of refreſhment to the caravans when they were allowed to paſs from Egypt to Ethiopia. From thence turning to the north-eaſt it meets with a chain of mountains in about 22° 15′ of N. latitude, where is the ſeventh cataract named *Jan Adel*. This is likewiſe very tremendous, though not above half as high as that of Alata. This courſe is now continued till it falls into the Mediterranean; there being only one other cataract in the whole ſpace, which is much inferior to any of thoſe already deſcribed.

This very particular and elaborate account of the ſources of the Nile and of the courſe of the river given by Mr Bruce, hath not eſcaped criticiſm. We find him accuſed by the reviewers, not only of having brought nothing to light that was not previouſly known to the learned, but even of having revealed nothing which was not previouſly publiſhed in Guthrie's Geographical Grammar. This, however, ſeems by no means a fair and candid criticiſm. If the ſources of the Nile, as deſcribed by Mr Bruce, were known to the author of Guthrie's Grammar, they muſt likewiſe have been ſo to every retailer of geography ſince the time of the miſſionaries; which, as the reviewers have particularized that book, would not ſeem to have been the caſe. If any thing new was publiſhed there previous to the appearance of Mr Bruce's work, it muſt probably have been derived indirectly from himſelf; of which clandeſtine method of proceeding that gentleman has had frequent occaſion to complain in other caſes. It is alleged, however, that he has given the name of *Nile* to a ſtream which does not deſerve it. This, like all other large rivers, is compoſed of innumerable branches; to viſit the top of every one of which would be indeed an Herculean taſk. The ſource of the largeſt branch therefore, and that which has the longeſt courſe, is undoubtedly to be accounted the ſource of the river; but here it is denied that Mr Bruce had ſufficient information. "Of the innumerable ſtreams (ſay they) that feed the lake of Tzana, there is one that ends in a bog, to which Mr Bruce was conducted by Woldo, a lying guide, who told him it was the ſource of the Nile. Mr Bruce, in a matter of far leſs importance, would not have taken Woldo's word; but he is perſuaded, that in this caſe he ſpoke truth; becauſe the credulous barbarians of the neighbouring diſtrict paid ſomething like worſhip to this brook, which, at the diſtance of 14 miles from its ſource, is not 20 feet broad, and nowhere one foot deep. Now it is almoſt unneceſſary to obſerve, that the natives of that country being, according to Mr Bruce's report, pagans, might be expected to worſhip the pure and ſalutary ſtream; to which, with other extraordinary qualities, their ſuperſtition aſcribed the power of curing the bite of a mad dog. Had he traced to its ſource any of the other rivulets which run into the lake Tzana, it is not unlikely that he might have met with ſimilar inſtances of credulity among the ignorant inhabitants of its banks. Yet this would not prove any one of them in particular to be the head of the Nile. It would be trifling with the patience of our readers to ſay one word more on the queſtion, whether the Portugueſe Jeſuits or Mr Bruce diſcovered what they erroneouſly call the head of the Nile. Before either they or he had indulged themſelves in a vain triumph over the labours of antiquity, they ought to have been ſure that they had effected what antiquity was unable to accompliſh. Now the river deſcribed by the Jeſuit Kircher, who collected the information of his brethren, as well as by Mr Bruce, is not the Nile of which the ancients were in queſt. This is amply proved by the prince of modern geographers, the incomparable D'Anville (at leaſt till our own Rennel appeared), in a copious Memoir publiſhed in the 26th volume of the Memoirs of the Academy of Belles Lettres, p. 45.—To this learned diſſertation we refer our readers; adding only what ſeems probable from the writings of Diodorus Siculus and Herodotus, that the ancients had two meanings when they ſpoke of the head or ſource of the Nile: Firſt, Literally, the head or ſource of that great weſtern ſtream now called the *White River*; which contains a much greater weight of waters, and has a much longer courſe than the river deſcribed by the Jeſuits and by Mr Bruce: and, 2dly, Metaphorically, the cauſe of the Nile's inundation.—This cauſe they had diſcovered to be the tropical rains, which fall in the extent of 16 degrees on each ſide of the line; which made the ſacriſtan of Minerva's temple of Sais in Egypt tell that inquiſitive traveller Herodotus, that the waters of the Nile run in two oppoſite directions from its ſource; the one north into Egypt, the other ſouth into Ethiopia; and the reports of all travellers into Africa ſerve to explain and confirm this obſervation. The tropical rains they acknowledge, give riſe to the Nile and all its tributary ſtreams which flow northward into the kingdom of Sennaar, as well as to the Zebee, and ſo many large rivers which flow ſouth into Ethiopia; and then, according to the inclination of the ground, fall into the Indian or Atlantic ocean. Such then, according to the Egyptian prieſts, is the true and philoſophical ſource of the Nile; a ſource diſcovered above 3000 years ago, and not, as Mr Bruce and the Jeſuits have ſuppoſed, the head of a paltry rivulet, one of the innumerable ſtreams that feed the lake Tzana."

On this ſevere criticiſm, however, it is obvious to remark, that if the ſource of the Nile had been diſcovered ſo many years ago, there is not the leaſt probability that the finding of it ſhould have been deemed an impoſſible undertaking, which it moſt certainly was, by the ancients.—That the finding out the fountains of the river itſelf was an object of their inquiry, cannot be doubted; and from the accounts given by Mr Bruce, it appears very evident that none of the ancients had equal ſucceſs with himſelf; though indeed the Jeſuits, as has already been obſerved, ſeem to have a right to diſpute it with him. From the correſpondence of his accounts with that of the Jeſuits, it appears certain that the moſt conſiderable ſtream which flows into the lake Tzana takes its riſe from the fountains at Geeſh already deſcribed; and that it is the moſt conſiderable plainly appears from its ſtream being viſible through the whole breadth of the lake, which is not the caſe with any of the reſt. The preference given to this ſtream by the Agows, who worſhip it, ſeems alſo an inconteſtable proof that they look upon it to be the great river which paſſes through Ethiopia and Egypt; nor will the argument of the reviewers hold good in *ſuppoſing* that other ſtreams are worſhipped, unleſs they could prove that they are ſo. As little can it be any objection or diſparagement to Mr Bruce's labours, that he did not diſcover the ſources of the weſtern branch of the Nile called the *White River*. Had he done ſo, it might next have been objected that he did not viſit the ſprings of the Tacazze, or any other branch. That the origin of the White river was unknown to the ancients may readily be allowed; but ſo were the fountains of Geeſh, as evidently appears from the erroneous poſition of the ſources of the eaſtern branch of the Nile laid down by Ptolemy. Our traveller, therefore, certainly has the merit, if not of diſcovering the ſources, at leaſt of confirming the accounts which the Jeſuits have given of the ſources, of the river called the *Nile*; and of which the White river, whether greater or ſmaller, ſeems to be accounted only a branch. The ſuperior veneration paid to the eaſtern branch of this celebrated river will alſo appear from the variety of names given to it, as well as from the import of theſe names; of which Mr Bruce gives the following account.

By the Agows it is named *Gzeir*, *Geeſa*, or *Seir;* the firſt of which term ſignifies *a god*. It is likewiſe named *Ab*, father; and has many other names, all of them implying the moſt profound veneration. Having deſcended into Gojam it is named *Abay;* which, according to Mr Bruce, ſignifies the river that ſuddenly ſwells and overflows periodically with rain. By the Gongas on the ſouth ſide of the mountains Dyre and Tagla, it is called *Dabli*, and by thoſe on the north ſide *Kowaſs;* both of which names ſignify a *watching dog*, the *latrator anubis*, or *dog-ſtar*. In the plain country between Fazurlo and Sennaar it is called *Nile* which ſignifies *blue;* and the Arabs interpret this name by the word *Azergue;* which name it retains till it reaches Halfaia, where it receives the White river.

Formerly the Nile had the name of *Siris*, both before and after it enters Beja, which the Greeks imagined was given to it on account of its black colour during the inundation; but Mr Bruce aſſures us that the river has no ſuch colour. He affirms, with great probability, that this name in the country of Beja imports the river of the *dog-ſtar*, on whoſe vertical appearance this river overflows; "and this idolatrous worſhip (ſays he) was probably part of the reaſon of the queſtion the prophet Jeremiah aſks: And what haſt thou to do in Egypt to drink the water of Seir, or the water profaned by idolatrous rites?" As for the firſt, it is only the tranſlation of the word *bahar* applied to the Nile. The inhabitants of the Barabra to this day call it *Bahar el Nil*, or the ſea of the Nile, in contradiſtinction to the Red ſea, for which they have no other name than *Bahar el Molech*, or the Salt ſea. The junction of the three great rivers, the Nile flowing on the weſt ſide of Meroe; the Tacazze, which waſhes the eaſt ſide, and joins the Nile at Maggiran in N. Lat. 17°; and the Mareb, which falls into this laſt ſomething above the junction, gives the name of *Triton* to the Nile.

The name *Ægyptus*, which it has in Homer, and which our author ſuppoſes to have been a very ancient name even in Ethiopia, is more difficult to account for. This has been almoſt univerſally ſuppoſed to be derived from the black colour of the inundation; but Mr Bruce, for the reaſons already given, will not admit of this. "Egypt (ſays he) in the Ethiopic is called *y Gipt*, Agar; and an inhabitant of the country, *Gypt*, for preciſely ſo it is pronounced; which means the country of ditches or canals, drawn from the Nile on both ſides at right angles with the river: nothing ſurely is more obvious than to write *y Gipt*, ſo pronounced, *Egypt;* and, with its termination *us* or *os*, *Egyptus*. The Nile is alſo called *Kronides*, Jupiter; and has had ſeveral other appellations beſtowed upon it by the poets; though theſe are rather of a tranſitory nature than to be ranked among the ancient names of the river. By ſome of the ancient fathers it has been named *Geon;* and by a ſtrange train of miracles they would have it to be one of the rivers of the terreſtrial paradiſe; the ſame which is ſaid to have encompaſſed the whole land of Cuſh or Ethiopia. To effect this, they are obliged to bring the river a great number of miles, not only under the earth, but under the ſea alſo; but ſuch reveries need no refutation.

Under the article EGYPT we have ſo fully explained the cauſe of the annual inundation of the Nile, that, with regard to the phenomenon itſelf, nothing farther ſeems neceſſary to be added. We ſhall therefore only extract from Mr Bruce's work what he has ſaid concerning the mode of natural operation by which the tropical rains are produced; which are now univerſally allowed to be the cauſe of the annual overflowing of this and other rivers.

According to this gentleman, the air is ſo much rarefied by the ſun during the time that he remains almoſt ſtationary over the tropic of Capricorn, that the other winds loaded with vapours ruſh in upon the land from the Atlantic ocean on the weſt, the Indian ocean on the eaſt, and the cold Southern ocean beyond the Cape. Thus a great quantity of vapour is gathered, as it were, into a focus; and as the ſame cauſes continue to operate during the progreſs of the ſun n[illegible]ward, a vaſt train of clouds proceed from ſouth to north, which, Mr Bruce informs us, are ſometimes extended much farther than at other times. Thus he tells us, that for two years ſome white dappled clouds were ſeen at Gondar, on the 7th of January; the ſun being then 34° diſtant from the zenith, and not the leaſt cloudy ſpeck having been ſeen for ſeveral mouths before. About the firſt of March, however, it begins to rain at Gondar but only for a few minutes at a time in large drops; the ſun being then about 5° diſtant from the zenith. The rainy ſeaſon commences with violence at every place when the ſun comes directly over it; and before it commences at Gondar, green boughs and leaves appear floating in the Bahar el Abiad, or White river, which, according to the accounts given by the Galla, our author ſuppoſes to take its riſe in about 5° north latitude.

The rains therefore precede the ſun only about 5°; but they continue and increaſe after he has paſſed it. In April all the rivers in the ſouthern parts of Abyſſinia begin to ſwell, and greatly augment the Nile, which is now alſo farther augmented by the vaſt quantity of water poured into the lake Tzana. On the firſt days of May, the ſun paſſes the village of Gerri, which is the limit of the tropical rains; and it is very remarkable, that, though the ſun ſtill continues to operate with unabated vigour, all his influence cannot bring the clouds farther northward than this village; the reaſon of which Mr Bruce, with great reaſon, ſuppoſes, to be the want of mountains to the northward. In confirmation of this opinion, he obſerves, that the tropical rains ſtop at the latitude of 14° inſtead of 16° in the weſtern part of the continent. All this time, however, they continue violent in Abyſſinia; and in the beginning of June the rivers are all full, and continue ſo while the ſun remains ſtationary in the tropic of Cancer.

This exceſſive rain, which would ſweep off the whole ſoil of Egypt into the ſea were it to continue without intermiſſion, begins to abate as the ſun turns ſouthward; and on his arrival at the zenith of each place, on his paſſage towards that quarter, they ceaſe entirely: the reaſon of which is no leſs difficult to be diſcovered than that of their coming on when he arrives at the zenith in his paſſage northward. Be the reaſon what it will, however, the fact is certain; and not only ſo, but the time of the rains ceaſing is exact to a ſingle day; inſomuch, that on the 25th of September the Nile is generally found to be at its higheſt at Cairo, and begins to diminiſh every day after. Immediately after the ſun has paſſed the line, he begins the rainy ſeaſon to the ſouthward; the rains conſtantly coming on with violence as he approaches the zenith of each place; but the inundation is now promoted in a different manner, according to the difference of circumſtances in the ſituation of the places. From about 6° S. Lat. a chain of high mountains runs all the way along the middle of the continent towards the Cape of Good Hope, and interſects the ſouthern part of the peninſula nearly in the ſame manner that the Nile does the northern. A ſtrong wind from the ſouth, ſtopping the progreſs of the condenſed vapours, daſhes them againſt the cold ſummits of this ridge of mountains, and forms many rivers, which eſcape in the direction either of eaſt or weſt as the level preſents itſelf. If this is towards the weſt, they fall down the ſides of the mountains into the Atlantic, and if on the eaſt into the Indian ocean.—"The clouds (ſays Mr Bruce), drawn by the violent action of the ſun, are condenſed, then broken, and fall as rain on the top of this high ridge, and ſwell every river; while a wind from the ocean on the eaſt blows like a monſoon up each of theſe ſtreams, in a direction contrary to their current during the whole time of the inundation; and this enables boats to aſcend into the weſtern parts of Sofala, and the interior country, to the mountains where lies the gold. The ſame effect, from the ſame cauſe, is produced on the weſtern ſide towards the Atlantic; the high ridge of mountains being placed between the different countries weſt and eaſt, is at once the ſource of their riches, and of thoſe rivers which conduct to the treaſures, which would be otherwiſe inacceſſible, in the eaſtern parts of the kingdoms of Benin, Congo, and Angola.

"There are three remarkable appearances attending the inundation of the Nile. Every morning in Abyſſinia is clear, and the ſun ſhines. About nine, a ſmall cloud, not above four feet broad, appears in the eaſt, whirling violently round as if upon an axis; but arrived near the zenith, it firſt abates its motion, then loſes its form, and extends itſelf greatly, and ſeems to call up vapours from all the oppoſite quarters. Theſe clouds having attained nearly the ſame height, ruſh againſt each other with great violence, and put me always in mind of Eliſha foretelling rain on Mount Carmel. The air, impelled before the heavieſt maſs, or ſwifteſt mover, makes an impreſſion of its form on the collection of clouds oppoſite; and the moment it has taken poſſeſſion of the ſpace made to receive it, the moſt violent thunder poſſible to be conceived inſtantly follows, with rain: after ſome hours the ſky again clears, with a wind at north: and it is always diſagreeably cold when the thermometer is below 63°.

"The ſecond thing remarkable is the variation of the thermometer. When the ſun is in the ſouthern tropic, 36° diſtant from the zenith of Gondar, it is ſeldom lower than 72°; but it falls to 60°, and 63°, when the ſun is immediately vertical; ſo happily does the approach of rain compenſate the heat of a too ſcorching ſun.

The third is that remarkable ſtop in the extent of the rain northward, when the ſun, that has conducted the vapours from the line, and ſhould ſeem now more than ever to be in the poſſeſſion of them, is here overruled ſuddenly; till, on its return to Gorri, again it reſumes the abſolute command over the rain, and reconducts it to the line, to furniſh diſtant deluges to the ſouthward."

With regard to the Nile itſelf, it has been ſaid that the quantity of earth brought down by it from Abyſſinia is ſo great, that the whole land of Egypt is produced from it. This queſtion, however, is diſcuſſed under the article EGYPT, where it is ſhown that this cannot poſſibly be the caſe.—Among other authorities there quoted was that of Mr Volney, who ſtrenuouſly argues againſt the opinion of Mr Savary and others, who have maintained that Egypt is the gift of the Nile. Notwithſtanding this, however, we find him aſſerting that the ſoil of Egypt has undoubtedly been augmented by the Nile: in which caſe it is not unreaſonable to ſuppoſe that it has been produced by it altogether.—"The reader (ſays he) will conclude, doubtleſs, from what I have ſaid, that writers have flattered themſelves too much in ſuppoſing they could fix the preciſe limits of the enlargement and riſe of the Delta. But, though I would reject all illuſory circumſtances, I am far from denying the fact to be well founded; it is too plain from reaſon, and an examination of the country. The riſe of the ground appears to me demonſtrated by an obſervation on which little ſtreſs has been laid. In going from Roſetta to Cairo, when the waters are low, as in the month of March, we may remark, as we go up the river, that the ſhore riſes gradually above the water; ſo that if overflowed two feet at Roſetta, it overflows from three to four at Faoua, and upwards of twelve at Cairo (A). Now by reaſoning from this fact, we may deduce the proof of an increaſe by ſediment; for the layer of mud being in proportion to the thickneſs of the ſheets of water by which it is depoſited, muſt be more or leſs conſiderable as theſe are of a greater or leſs depth; and we have ſeen that the like gradation is obſervable from Aſouan to the ſea.

"On the other hand, the increaſe of the Delta manifeſts itſelf in a ſtriking manner, by the form of Egypt along the Mediterranean. When we conſider its figure on the map, we perceive that the country which is in the line of the river, and evidently formed of foreign materials, has aſſumed a ſemicircular ſhape, and that the ſhores of Arabia and Africa, on each ſide, have a direction towards the bottom of the Delta; which manifeſtly diſcovers that this country was formerly a gulf, that in time has been filled up.

"This accumulation is common to all rivers, and is accounted for in the ſame manner in all: the rain water and the ſnow deſcending from the mountains into the valleys, hurry inceſſantly along with them the earth they waſh away in their deſcent. The heavier parts, ſuch as pebbles and ſands, ſoon ſtop, unleſs forced along by a rapid current. But when the waters meet only with a fine and light earth, they carry away large quantities with the greateſt facility. The Nile, meeting with ſuch a kind of earth in Abyſſinia and the interior parts of Africa, its waters are loaded and its bed filled with it; nay, it is frequently ſo embarraſſed with this ſediment as to be ſtraitened in its courſe. But when the inundation reſtores to it its natural energy, it drives the mud that has accumulated toward the ſea, at the ſame that it brings down more for the enſuing ſeaſon; and this, arrived at its mouth, heaps up, and forms ſhoals, where the declivity does not allow ſufficient action to the current, and where the ſea produces an equilibrium of reſiſtance. The ſtagnation which follows occaſions the groſſer particles, which till then had floated, to ſink; and this takes place more particularly in thoſe places where there is leaſt motion, as towards the ſhores, till the ſides become gradually enriched by the ſpoils of the upper country and of the Delta itſelf; for if the Nile takes from Abyſſinia to give to the Thebais, it likewiſe takes from the Thebais to give to the Delta, and from the Delta to carry to the ſea. Wherever its waters have a current, it deſpoils the ſame territory that it enriches. As we aſcend towards Cairo, when the river is low, we may obſerve the banks worn ſteep on each ſide and crumbling in large flakes. The Nile, which undermines them, depriving their light earth of ſupport, it falls into the bed of the river; for when the water is high, the earth imbibes it; and when the ſun and drought return, it cracks and moulders away in great flakes, which are hurried along by the Nile."

Thus does Mr Volney argue for the increaſe of the Delta in the very ſame manner that others have argued for the production of the whole country of Egypt; an opinion which he is at great pains to refute. Under the article EGYPT, however, it is ſhown that the Nile does not bring down any quantity of mud ſufficient for the purpoſes aſſigned; and with regard to the argument drawn from the ſhallowneſs of the inundation when near the ſea, this does not prove any riſe of the land; but as Mr Rennel has judiciouſly obſerved in his remarks on the inundation of the Ganges, ariſes from the nature of the fluid itſelf. The reaſon, in ſhort, is this: The ſurface of the ſea is the loweſt point to which the waters of every inundation have a tendency; and when they arrive there, they ſpread themſelves over it with more eaſe than anywhere elſe, becauſe they meet with leſs reſiſtance. Their motion, however, by reaſon of the ſmall declivity, is leſs ſwift than that of the waters farther up the river, where the declivity is greater; and conſequently the latter being ſomewhat impeded in their motion, are in ſome degree accumulated. The ſurface of the inundation therefore, does not form a perfectly level plain, but one gradually ſloping from the interior parts of the country towards the ſea; ſo that at the greateſt diſtance from the ocean the water will always be deepeſt, even if we ſhould ſuppoſe the whole country to be perfectly ſmooth, and compoſed of the moſt ſolid materials.—This theory is eaſily underſtood from obſerving a quantity of water running along a wooden ſpout, which is always more ſhallow at the end of the ſpout where it runs off than at the other.—With regard to Mr Volney's other arguments, they are without doubt contradictory; for if, as he ſays, the river takes from Abyſſinia to give to the Thebais, from Thebais to give to the Delta, and from Delta to the ſea, it undoubtedly follows, that is gives nothing to any part of the land whatever, but that altogether is ſwept into the Mediterranean ſea; which, indeed, ſome very trifling quantities excepted, is moſt probably the caſe.

It has been remarked by Mr Pococke, a very judicious traveller, that, in the beginning of the inundation, the waters of the Nile turn red, and ſometimes green; and while they remain of that colour, they are unwholeſome. He explains this phenomenon by ſuppoſing, that the inundation at firſt brings away that red or green filth which may be about the lakes where it takes its riſe; or about the ſources of the ſmall rivers which flow into it, near its principal ſource; "for, ſays he, although there is ſo little water in the Nile when at loweſt, that there is hardly any current in many parts of it, yet it cannot be ſuppoſed that the water ſhould ſtagnate in the bed of the Nile ſo as to become green. Afterwards the water begins to be red and ſtill more turbid, and then it begins to be wholeſome."—This circumſtance is explained by Mr Bruce in the following manner: The country about Narea and Caffa, where the river Abiad takes its riſe, is full of immenſe marſhes, where, during the dry ſeaſon, the water ſtagnates, and becomes impregnated with every kind of corrupted matter. Theſe, on the commencement of the rains, overflow into the river Abiad, which takes its riſe there. The overflowing

---

(A) "It would be curious to aſcertain in what proportion it continues up to Aſouan. Some Copts, whom I have interrogated on the ſubject, aſſured me that it was much higher through all the Said than at Cairo."

of theſe vaſt marſhes firſt carried the diſcoloured water into Egypt; after which follows that of the great lake Tzana, through which the Nile paſſes; which having been ſtagnated, and without rain, under a ſcorching ſun for ſix months, joins its putrid waters to the former. In Abyſſinia alſo, there are very few rivers that run after November, but all of them ſtand in prodigious pools, which, by the heat of the ſun, likewiſe turn putrid, and on the commencement of the rains throw off their ſtagnant water into the Nile; but at laſt, the rains becoming conſtant, all this putrid matter is carried off, and the ſources of the inundation become ſweet and wholeſome. The river then paſſing through the kingdom of Sennaar, the ſoil of which is this red bole, becomes coloured with that earth; and a mixture, along with the moving ſands of the deſerts, of which it receives a great quantity when raiſed by the wind, precipitates all the viſcous and putrid matters which float in the waters; whence Mr Pococke judiciouſly obſerves, that the Nile is not wholeſome when the water is clear and green, but when ſo red and turbid that it ſtains the water of the Mediterranean.

The rains in Abyſſinia, which ceaſe about the 8th of September, generally leave a ſickly ſeaſon in the low country; but the diſeaſes produced by theſe rains are removed by others which come on about the end of October, and ceaſe about the 8th of November. On theſe rains depend the latter crops of the Abyſſinians; and for theſe the Agows pray to the river, or the genius or ſpirit reſiding in it. In Egypt, however, the effect of them is ſeldom perceived; but in ſome years they prove exceſſive: and it has been obſerved that the Nile, after it has fallen, has again riſen in ſuch a manner as to alarm the whole country. This is ſaid to have happened in the time of Cleopatra, when it was ſuppoſed to preſage the extinction of the government of the Ptolemies; and in 1737 it was likewiſe imagined to portend ſome dreadful calamity.

The quantity of rain, by which all this inundation is occaſioned, varies conſiderably in different years; at leaſt at Gondar, where Mr Bruce had an opportunity of meaſuring it. In 1770 it amounted to 35½ inches; but in 1771 it amounted to no leſs than 41.355 inches from the vernal equinox to the 8th of September.—What our author adds concerning the variation of the rainy months ſeems totally irreconcilable with what he had before advanced concerning the extreme regularity of the natural cauſes by which the tropical rains are produced. "In 1770 (ſays he) Auguſt was the rainy month; in 1771, July.—When July is the rainy month, the rains generally ceaſe for ſome days in the beginning of Auguſt, and then a prodigious deal falls in the latter end of that month and firſt week of September. In other years July and Auguſt are the violent rainy months, while June is fair. And laſtly, in others, May, June, July, Auguſt and the firſt week of September."—If this is the caſe, what becomes of the regular attraction of the clouds by the ſun as he advances northward; of the coming on of the rains when he arrives at the zenith of any place, in his paſſage to the tropic of Cancer; and of their ceaſing when he comes to the ſame point in his return ſouthward.

Under the article **Ethiopia** we have mentioned a threat of one of the Abyſſinian monarchs, that he would direct the courſe of the Nile and prevent it from fertilizing the land of Egypt; and it has likewiſe been related, that conſiderable progreſs was made in this undertaking by another emperor. Mr Bruce has beſtowed an entire chapter on the ſubject; and is of opinion, that "there ſeems to be no doubt that it is poſſible to diminiſh or divert the courſe of the Nile, that it ſhould be inſufficient to fertilize the country of Egypt; becauſe the Nile, and all the rivers that run into it, and all the rains that ſwell theſe rivers, fall in a country two miles above the level of the ſea; therefore it cannot be denied, that there is level enough to divert many of the rivers into the Red ſea, or perhaps ſtill eaſier by turning the courſe of the river Abiad till it meets the level of the Niger, or paſs through the deſert into the Mediterranean.——Alphonſo Albuquerque is ſaid to have written frequently to the king of Portugal to ſend him pioneers from Madeira, with people accuſtomed to level grounds, and prepare them for ſugar canes; by whoſe aſſiſtance he meant to turn the Nile into the Red ſea. This undertaking, however, if it really had been projected, was never accompliſhed; nor indeed is there any probability that ever ſuch a mad attempt was propoſed. Indeed, though we cannot deny that there is a poſſibility in nature of accompliſhing it, yet the vaſt difficulty of turning the courſe of ſo many large rivers may juſtly ſtigmatize it as impracticable; not to mention the obſtacles which muſt naturally be ſuggeſted from the apparent inutility of the undertaking, and thoſe which would ariſe from the oppoſition of the Egyptians.

It has already been obſerved in a quotation from the reviewers, that Herodotus was informed by the ſacriſtan or ſecretary of the treaſury of Minerva, that one half of the waters of the Nile run north and the other ſouth. This is alſo taken notice of by Mr Bruce; who gives the following explanation of it. "The ſecretary was probably of that country himſelf, and ſeems by his obſervation to have known more of it than all the ancients together. In fact we have ſeen, that between 13° and 14° north latitude, the Nile, with all its tributary ſtreams, which have their riſe and courſe within the tropical rains, falls down into the flat country (the kingdom of Sennaar), which is more than a mile lower than the high country in Abyſſinia; and thence, with a little inclination, it runs into Egypt. Again, In latitude 9°, in the kingdom of Gingiro, the Zebee runs ſouth or ſouth-eaſt, into the Inner Ethiopia, as do alſo many other rivers, and, as I have heard from the natives of that country empty themſelves into a lake, as thoſe on the north ſide of the line do into the lake Tzana, thence diſtributing their waters to the eaſt and weſt. Theſe become the heads of great rivers, that run through the interior countries of Ethiopia (correſponding to the ſea coaſt of Melinda and Momboza) into the Indian ocean; whilſt, on the weſtward, they are the origin of the vaſt ſtreams that fall into the Atlantic, paſſing through Benin and Congo, ſouthward of the river Gambia and the Sierra Leona. In ſhort, the periodical rains from the tropic of Capricorn to the line, being in equal quantity with thoſe that fall between the line and the tropic of Cancer, it is plain, that if the land of Ethiopia ſloped equally from the line ſouthward and northward, the rains that fall ſhould go, the one half north and the other half ſouth; but as the ground from 5° north declines all ſouthward, it follows, that the rivers which run to the ſouthward muſt be equal to thoſe that run northward, *plus* the rain that falls in the 5° north latitude, where the ground begins to ſlope to the ſouthward; and there can be little doubt that this is at leaſt one of the reaſons why there are in the ſouthern continent ſo many rivers larger than the Nile, that run both into the Indian and Atlantic oceans."

From this account given to Herodotus, it has been ſuppoſed, by ſome writers on geography, that the Nile divides itſelf into two branches, one of which runs northward into Egypt, and one through the country of the Negroes weſtward into the Atlantic ocean. This opinion was firſt broached by Pliny.—It has been adopted by the Nubian geographer, who urges in ſupport of it, that if the Nile carried down all the rains which fall into it from Abyſſinia, the people of Egypt would not be ſafe in their houſes. But to this Mr Bruce anſwers, that the waſte of water in the burning deſerts through which the Nile paſſes is ſo great, that unleſs it was ſupplied by another ſtream, the White River, equal in magnitude to itſelf, and which, riſing in a country of perpetual rains, is thus always kept full, it never could reach Egypt at all, but would be loſt in the ſands, as is the caſe with many other very conſiderable rivers in Africa. "The rains (ſays he) are collected by the four great rivers in Abyſſinia; the Mareb, the Bowiha, the Tacazze, and the Nile. All theſe principal, and their tributary ſtreams, would, however, be abſorbed, nor be able to paſs the burning deſerts, or find their way into Egypt, were it not for the White River, which having its ſource in a country of almoſt perpetual rains, joins to it a never-failing ſtream equal to the Nile itſelf."

We ſhall conclude this article with ſome account of the Agows who inhabit the country about the ſources of the Nile. Theſe, according to Mr Bruce, are one of the moſt conſiderable nations in Abyſſinia, and can bring into the field about 4000 horſe and a great number of foot; but were once much more powerful than they are now, having been greatly reduced by the invaſions of the Galla. Their province is nowhere more than 60 miles in length, or than 30 in breadth; notwithſtanding which they ſupply the capital and all the neighbouring country with cattle, honey, butter, wax, hides, and a number of other neceſſary articles; whence it has been cuſtomary for the Abyſſinian princes to exact a tribute rather than military ſervice from them. The butter is kept from putrefaction during the long carriage, by mixing it with a ſmall quantity of a root ſomewhat like a carrot, which they call *mormoco*. It is of a yellow colour, and anſwers the purpoſe perfectly well; which in that climate it is very doubtful if ſalt could do. The latter is beſides uſed as money; being circulated inſtead of ſilver coin, and uſed as change for gold. Brides paint their feet, hands, and nails, with this root. A large quantity of the ſeed of the plant was brought into Europe by Mr Bruce.

The Agows carry on a conſiderable trade with the Shangalla and other black ſavages in the neighbourhood; exchanging the produce of their country for gold, ivory, horns of the rhinoceros, and ſome fine cotton. The barbarity and thieviſh diſpoſition of both nations, however, render this trade much inferior to what it might be.

In their religion the Agows are groſs idolators, paying divine honours to the Nile, as has already been obſerved. Mr Bruce who lodged in the houſe of the prieſt of the river, had an opportunity of becoming acquainted with many particulars of their devotion. He heard him addreſs a prayer to the Nile, in which he ſtyled it the "Moſt High God, the Saviour of the world. In this prayer he petitioned for ſeaſonable rain, plenty of graſs, and the preſervation of a kind of ſerpents; deprecating thunder very pathetically. The moſt ſublime and lofty titles are given by them to the ſpirit which they ſuppoſe to reſide in the river Nile; calling it everlaſting God, Light of the World, Eye of the World, God of Peace, their Saviour, and Father of the Univerſe.

The Agows are all clothed in hides, which they manufacture in a manner peculiar to themſelves. Theſe hides are made in the form of a ſhirt reaching down to their feet, and tied about the middle with a kind of ſaſh or girdle. The lower part of it reſembles a large double petticoat; one fold of which they turn back over their ſhoulders, faſtening it with a broach or ſkewer acroſs their breaſt before, and the married women carry their children in it behind. The younger ſort generally go naked. The women are marriageable at nine years of age, though they commonly do not marry till eleven; and they continue to bear children till 30, and ſometimes longer. They are generally thin and below the middle ſize, as well as the men. Barrenneſs is quite unknown among them.

The country of the Agows has a very elevated ſituation, and is of courſe ſo temperate that the heat may eaſily be borne, though little more than 10° from the equator. The people, however, are but ſhort lived; which may in part be owing to the oppreſſion they labour under. This, according to Mr Bruce, is exceſſive. "Though their country (ſays he) abounds with all the neceſſaries of life, their taxes, tributes, and ſervices, eſpecially at preſent, are ſo multiplied upon them, whilſt their diſtreſſes of late have been ſo great and frequent, that they are only the manufacturers of the commodities they ſell, to ſatisfy theſe conſtant exorbitant demands, and cannot enjoy any part of their own produce themſelves, but live in penury and miſery ſcarce to be conceived. We ſaw a number of women wrinkled and ſun-burnt ſo as ſcarce to appear human, wandering about under burning ſun, with one and ſometimes two children upon their backs; gathering the ſeeds of bent graſs to make a kind of bread.

NILOMETER, or Niloscope, an inſtrument uſed among the ancients to meaſure the height of the water of the river Nile in its overflowings.

The word comes from Νειλος Nile (and that from νεα ιλυς "new mud," or as ſome others would have it, from νεω, "I flow," and ιλυς, "mud,") and μετρον, "meaſure." The Greeks more ordinarily call it, Νειλοσκοπιον.

The nilometer is ſaid, by ſeveral Arabian writers, to have been firſt ſet up, for this purpoſe, by Joſeph during his regency in Egypt: the meaſure of it was 16 cubits, this being the height of the increaſe of the Nile, which was neceſſary to the fruitfulneſs of Egypt.

From the meaſure of this column, Dr Cumberland * deduces an argument, in order to prove that the Jewiſh and Egyptian cubit were of the ſame length.

In the French king's library is an Arabic treatiſe on nilometers, entitled *Neil fi alnal al Nil;* wherein are deſcribed all the overflowings of the Nile, from the firſt year of the Hegira to the 875th.

Herodotus mentions a column erected in a point of the iſland Delta, to ſerve as a nilometer; and there is ſtill one of the ſame kind in a moſque of the ſame place.

As all the riches of Egypt ariſe from the inundations of the Nile, the inhabitants uſed to ſupplicate them at the hands of their Serapis; and committed the moſt execrable crimes, as actions, forſooth, of religion, to obtain the favour. This occaſioned Conſtantine expreſsly to prohibit theſe ſacrifices, &c. and to order the nilometer to be removed into the church; whereas, till that time, it had been in the temple of Serapis. Julian the Apoſtate had it replaced in the temple, where it continued till the time of Theodoſius the Great.

The only rational and conſiſtent account, however, which we have of the nilometer is given by the celebrated traveller Mr Bruce. "On the point † of the iſland Rhode, between Geeza and Cairo, near the middle of the river, is a round tower encloſing a neat well or ciſtern lined with marble. The bottom of this well is on the ſame level with the bottom of the Nile, which has free acceſs to it through a large opening like an aperture. In the middle of the well riſes a thin column of eight faces of blue and white marble; of which the foot is on the ſame plane with the bottom of the river. This pillar is divided into 20 peeks, of 22 inches each. Of theſe peeks the two lowermoſt are left, without any diviſion, to ſtand for the quantity of ſludge which the water depoſites there. Two peeks are then divided, on the right hand, into 24 digits each; then on the left, four peeks are divided into 24 digits; then on the right, four; and on the left another four: again, four on the right, which completes the number of 18 peeks from the firſt diviſion marked on the pillar, each peek being 22 inches. Thus the whole marked and unmarked amounts to ſomething more than 36 feet Engliſh.

On the night of St John, when, by the falling of the dew, they perceive the rain water from Ethiopia [illegible] with the Nile at Cairo, they begin to announce the elevation of the river, having then five peeks of water marked on the nilometer, and two unmarked for the ſludge, of which they take no notice. Their firſt proclamation, ſuppoſing the Nile to have riſen 12 digits, is 12 from 6, or it wants 12 digits to be ſix peeks. When it has riſen three more, it is nine from ſix; and ſo on, till the whole 18 be filled, when all the land of Egypt is fit for cultivation. Several canals are then opened, which convey the water into the deſert, and hinder any further ſtagnation on the fields. There is indeed a great deal of more water to come from Ethiopia; but were the inundation ſuffered to go on, it would not drain ſoon enough to fit the land for tillage: and to guard againſt this miſchief is the principal uſe of the nilometer, though the Turkiſh government makes it an engine of taxation. From time immemorial the Egyptians paid, as tribute to the king, a certain proportion of the fruit of the ground; and this was anciently aſcertained by the elevation of the water on the nilometer, and by the menſuration of the land actually overflowed. But the Saracen government, and afterwards the Turkiſh, has taxed the people by the elevation alone of the water, without attending to its courſe over the country, or the extent of the land actually overflowed; and this tax is ſometimes cruelly oppreſſive.

NIMBUS, in antiquity, a circle obſerved on certain medals, or round the heads of ſome emperors; anſwering to the circles of light drawn round the images of ſaints.

NIMEGUEN, a large, handſome, and ſtrong town of the Netherlands, and capital of Dutch Guelderland, with a citadel, an ancient palace, and ſeveral forts. It is noted for the peace concluded there in 1679. It has a magnificent town houſe, and the inhabitants are greatly given to trade. It is ſeated on the Vahal or Wahal, between the Rhine and the Maeſe. It is the utmoſt eaſtern boundary of the Netherlands. It contains two Dutch churches, a French Calviniſt and a Lutheran church, five Popiſh, and ſeveral hoſpitals. It was once a Hans-town and an imperial city. It is now the ſeat of government, has a canal to Arnheim, and conſiderable trade to ſome parts of Germany: it trades alſo in fine beer brewing, fattening of cattle, and exporting of its butter, which is extremely good, into all the other provinces. It is in E. Long. 5. 50. N. Lat. 51. 55.

NIMETULAHITES, a kind of Turkiſh monks, ſo called from their founder Nimetulahi, famous for his doctrines and the auſterity of his life.

NIMPO, a city and ſea-port town of China, in the province of Chekiang. It is ſeated on the eaſtern ſea of China, over againſt Japan. It is a city of the firſt rank, and ſtands at the confluence of two ſmall rivers, which, after their union, form a channel that reaches to the ſea, and is deep enough to bear veſſels of 200 tons burden. The walls of Nimpo are 5000 paces in circumference, and are built with freeſtone. There are five gates, beſides two water gates for the paſſage of barks into the city; a tower ſeveral ſtories high, built of bricks; and a long bridge of boats, faſtened together with iron chains, over a very broad canal. This city is commanded by a citadel built on a very high rock, by the foot of which all veſſels muſt neceſſarily paſs. The Chineſe merchants of Siam and Batavia go to this place yearly to buy ſilks, which are the fineſt in the empire. They have alſo a great trade with Japan, it being but two days ſail from hence: thither they carry ſilks, ſtuffs, ſugar, drugs, and wine; and bring back copper, gold, and ſilver. E. Long. 122. 0. N. Lat. 30. 0.

NIMROD, the ſixth ſon of Cuſh, and in all appearance much younger than any of his brothers: for Moſes mentions the ſons of Raamah, his fourth brother, before he ſpeaks of him. What the ſacred hiſtorian ſays of him is ſhort; and yet he ſays more of him than of any other of the poſterity of Noah, till he comes to Abraham. He tells us, that "Nimrod began to be a mighty one in the earth;" that he was

---

* *Scripture weights and meaſures,* p. 18.

† *Bruce's Travels.* Vol. III.

a "mighty hunter before the Lord," even to a proverb; and that "the beginning of his kingdom was Babel, and Erech, and Accad, and Calneh, in the land of Shinar."

From this account he is ſuppoſed to have been a man of extraordinary ſtrength and valour. Some repreſent him as a giant; all conſider him as a great warrior. It is generally thought, that by the words *a mighty hunter*, is to be underſtood, that he was a great tyrant; but ſome of the rabbins interpret theſe words favourably, ſaying, that Nimrod was qualified by a peculiar dexterity and ſtrength for the chaſe, and that he offered to God the game which he took; and ſeveral of the moderns are of opinion, that this paſſage is not to be underſtood of his tyrannical oppreſſions, or of hunting of men, but of beaſts. It muſt be owned, that the phraſe *before the Lord* may be taken in a favourable ſenſe, and as a commendation of a perſon's good qualities; but in this place the generality of expoſitors underſtand it otherwiſe.

Hunting muſt have been one of the moſt uſeful employments in the times juſt after the diſperſion, when all countries were over-run with wild beaſts, of which it was neceſſary they ſhould be cleared, in order to make them habitable; and therefore nothing ſeemed more proper to procure a man eſteem and honour in thoſe ages, than his being an expert hunter. By that exerciſe, we are told, the ancient Perſians fitted their kings for war and government; and hunting is ſtill, in many countries, conſidered as one part of a royal education.

There is nothing in the ſhort hiſtory of Nimrod which carries the leaſt air of reproach, except his name, which ſignifies a *rebel*; and that is the circumſtance which ſeems to have occaſioned the injurious opinions which have been entertained of him in all ages. Commentators, being prepoſſeſſed in general that the curſe of Noah fell upon the poſterity of Ham, and finding this prince ſtigmatized by his name, have interpreted every paſſage relating to him to his diſadvantage. They repreſent him as rebel againſt God, in perſuading the deſcendants of Noah to diſobey the divine command to diſperſe, and in ſetting them to build the tower of Babel, with an impious deſign of ſcaling heaven. They brand him as an ambitious uſurper, and an inſolent oppreſſor; and make him the author of the adoration of fire, of idolatrous worſhip given to men, and the firſt perſecutor on the ſcore of religion. On the other hand, ſome account him a virtuous prince, who, far from adviſing the building of Babel, left the country, and went into Aſſyria, becauſe he would not give his conſent to that project.

Nimrod is generally thought to have been the firſt king after the flood; though ſome authors, ſuppoſing a plantation or diſperſion prior to that of Babel, have made kings in ſeveral countries before his time. Mizraim is thought by many who contend for the antiquity of the Egyptian monarchy, to have begun his reign much earlier than Nimrod; and others, from the uniformity of the languages ſpoken in Aſſyria, Babylonia, Syria, and Canaan, affirm thoſe countries to have been peopled before the confuſion of tongues.

The four cities Moſes gives to Nimrod conſtituted a large kingdom in thoſe early times, when few kings had more than one; only it muſt be obſerved, that poſſeſſions might at firſt have been large, and afterwards divided into ſeveral parcels; and Nimrod being the leader of a nation, we may ſuppoſe his ſubjects ſettled within thoſe limits: whether he became poſſeſſed of thoſe cities by conqueſt or otherwiſe, does not appear; it is moſt probable he did not build Babel, all the poſterity of Noah ſeeming to have been equally concerned in that affair; nor does it appear that he built the other three, though the founding of them, and many more, with other works, are attributed to him by ſome authors. It may ſeem alſo a little ſtrange, that Nimrod ſhould be preferred to the regal dignity, and enjoy the moſt cultivated part of the earth then known, rather than any other of the elder chiefs or heads of nations, even of the branch of Ham. Perhaps it was conferred on him for his dexterity in hunting; or, it may be, he did not aſſume the title of king till after his father Cuſh's death, who might have been ſettled there before him, and left him the ſovereignty; but we incline to think, that he ſeized Shinar from the deſcendants of Shem, driving out Aſhur, who from thence went and founded Nineveh, and other cities in Aſſyria.

The Scripture does not inform us when Nimrod began his reign: Some date it before the diſperſion; but ſuch a conjecture does not ſeem to ſuit with the Moſaical hiſtory: for before the diſperſion we read of no city but Babel; nor could there well be more, while all mankind were yet in a body together; but when Nimrod aſſumed the regal title, there ſeem to have been other cities; a circumſtance which ſhews it was a good while after the diſperſion. [illegible] writers of the Univerſal Hiſtory place the [illegible] of his reign 30 years from that event, and in [illegible] lihood it ſhould be placed rather later than earlier.

Authors have taken a great deal of pains to find Nimrod in profane hiſtory: ſome have imagined him to be the ſame with Belus, the founder of the Babyloniſh empire; others take him to be Ninus, the firſt Aſſyrian monarch. Some believe him to have been Evechous, the firſt Chaldean king after the deluge; and others perceive a great reſemblance between him and Bacchus, both in actions and name. Some of the Mahommedan writers ſuppoſe Nimrod to have been Zohak, a Perſian king of the firſt dynaſty: others contend for his being Cay Caus, the ſecond king of the ſecond race; and ſome of the Jews ſay he is the ſame with Amraphel the king of Shinar, mentioned by Moſes. But there is no certainty in theſe conjectures, nor have we any knowledge of his immediate ſucceſſors.

The Scripture mentions nothing as to the death of Nimrod; but authors have taken care that ſuch an eſſential circumſtance in his hiſtory ſhould not be wanting. Some of the rabbins pretend he was ſlain by Eſau, whom they make his contemporary. There is a tradition that he was killed by the fall of the tower of Babel, which was overthrown by tempeſtuous winds. Others ſay, that as he led an army againſt Abraham, God ſent a ſquadron of gnats, which deſtroyed moſt of them; and particularly Nimrod, whoſe brain was pierced by one of thoſe inſects.

NINE, the laſt of the radical numbers or characters, from the combination of which any definite number, however large, may be produced. "It is obſerved by arithmeticians (ſays Hume), that the products of 9 compoſe always either 9 or ſome leſſer products of 9, if you add together all the characters of which any of the former products is compoſed: thus of 18, 27, 36, which are products of 9, you make 9, by adding 1 to 8, 2 to 7, 3 to 6. Thus 369 is a product alſo of 9; and if you add 3, 6, and 9, you make 18, a leſſer product of 9." See *Hume's Dialogues on Nat. Relig.* p. 167, 168, &c. 2d. edit.

NINEVEH (anc. geog.), the capital city of Aſſyria, founded by Aſhur the ſon of Shem (Gen. x. 11.); or, as others read the text, by Nimrod the ſon of Cuſh.

However this be, yet it muſt be owned, that Nineveh was one of the moſt ancient, the moſt famous, the moſt potent, and largeſt cities of the world. It is very difficult exactly to aſſign the time of its foundation; but it cannot be long after the building of Babel. It was ſituated upon the banks of the Tigris; and in the time of the prophet Jonas, who was ſent thither under Jeroboam II. king of Iſrael, and, as Calmet thinks, under the reign of Pul, father of Sardanapalus, king of Aſſyria, Nineveh was a very great city, its circuit being three days journey (Jonah iii. 3.) Diodorus Siculus, who has given us the dimenſions of it, ſays it was 480 ſtadia in circumference, or 47 miles; and that it was ſurrounded with lofty walls and towers; the former being 200 feet in height, and ſo very broad that three chariots might drive on them abreaſt; and the latter 200 feet in height, and 1500 in number; and Strabo allows it to have been much greater than Babylon. Diodorus Siculus was, however, certainly miſtaken, or rather his tranſcribers, as the authors of the Univerſal Hiſtory think, in placing Nineveh on the Euphrates, ſince all hiſtorians as well as geographers who ſpeak of that city, tell us in expreſs terms that it ſtood on the Tigris. At the time of Jonah's miſſion thither, it was ſo populous, that it was reckoned to contain more than ſix ſcore thouſand perſons, who could not diſtinguiſh their right hand from their left (Jonah iv. 11.), which is generally explained of young children that had not yet attained to the uſe of reaſon; ſo that upon this principle it is computed that the inhabitants of Nineveh were then above 600,000 perſons.

Nineveh was taken by Arbaces and Beleſis, in the year of the world 3257, under the reign of Sardanapalus, in the time of Ahaz king of Judah, and about the time of the foundation of Rome. It was taken a ſecond time by Aſtyages and Nabopolaſſar from Chynaladanus king of Aſſyria in the year 3378. After this time, Nineveh no more recovered its former ſplendour. It was ſo entirely ruined in the time of Lucianus Samoſatenſis, who lived under the emperor Adrian, that no footſteps of it could be found, nor ſo much as the place where it ſtood. However, it was rebuilt under the Perſians, and deſtroyed again by the Saracens about the ſeventh age.

Modern travellers ſay (A), that the ruins of ancient Nineveh may ſtill be ſeen on the eaſtern banks of the Tigris, oppoſite to the city Moſul or Mouſul: (See Mousul). Profane hiſtorians tell us, that Ninus firſt founded Nineveh; but the Scripture aſſures us, that it was Aſhur or Nimrod.

The ſacred authors make frequent mention of this city; and Nahum and Zephaniah foretold its ruin in a very particular and pathetic manner.

NINIA, or Ninian, commonly called *St Ninian*, a holy man among the ancient Britons. He reſided at or near a place called by Ptolemy *Lucopibia*, and by Bede *Candida Caſa*; but the Engliſh and Scotch called it *Whitherne*. We mention him, becauſe he is ſaid to have been the firſt who converted the Scots and Picts to the Chriſtian faith; which he did during the reign of Theodoſius the Younger. Bede informs us, that he built a church dedicated to St Martin, in a ſtyle unknown to the Britons of that time; and adds, that during his time the Saxons held this province (*Callovidia*, now *Galloway*), and that, as in conſequence of the labours of this ſaint the converts to Chriſtianity increaſed, an epiſcopal ſee was eſtabliſhed there. Dr Henry, conſidering that "few or none of the writings of the moſt ancient fathers of the Britiſh church are now extant, and ſince little being ſaid of them by their cotemporaries, we can know little of their perſonal hiſtory and of the extent of their erudition," gives a ſhort account of ſome of them. Of St Ninian he ſays, "he was a Briton of noble birth and excellent genius. After he had received as good an education at home as his own country could afford, he travelled for his further improvement, and ſpent ſeveral years at Rome, which was then the chief ſeat of learning as well as of empire. From thence he returned into Britain, and ſpent his life in preaching the goſpel in the moſt uncultivated parts of it, with equal zeal and ſucceſs."

There is a ſmall town called *St Ninian*, about a mile ſouth of Stirling. Its church had been occupied by the rebels in 1745 as a powder magazine; who on their return blew it up in ſuch haſte, as to deſtroy ſome of their own people and about fifteen ſpectators.

NING-PO-FOU, called by the Europeans *Liampo*, is an excellent port, on the eaſtern coaſt of China, oppoſite

---

(A) This aſſertion, however, is far from ſeeming probable; for every trace of it ſeems to have ſo totally diſappeared, even ſo early as A. D. 627, that the vacant ſpace afforded a ſpacious field for the celebrated battle between the emperor Heraclius and the Perſians. There are few things in ancient hiſtory which have more puzzled the learned world, than to determine the ſpot where this city ſtood. Mr Ives informs us, that ſome have imagined it ſtood near Jonah's tomb; others, however, place it at another place, ſome hours journey up the Tigris. Theſe different opinions, however, ſeem perfectly reconcilable; for it appears at leaſt probable, that ancient Nineveh took in the whole of the ground which lies between theſe two ruined places. Mr Ives adds, that "what confirms this conjecture is, that much of this ground is now hilly, owing no doubt to the rubbiſh of the ancient buildings. There is one mount of 200 or 300 yards ſquare, which ſtands ſome yards north-eaſt of Jonah's tomb, whereon it is likely a fortification once ſtood. It ſeems to have been made by nature, or perhaps both by nature and art, for ſuch an uſe."

Ninon
||
Nio.

ſite to Japan. Eighteen or twenty leagues from this place is an iſland called *Tcheou-ſhan*, where the Engliſh firſt landed on their arrival at China.

The ſilks manufactured at Ning-po are much eſteemed in foreign countries, eſpecially in Japan, where the Chineſe exchange them for copper, gold, and ſilver. This city has four others under its juriſdiction, beſides a great number of fortreſſes.

NINON L'Enclos, a celebrated lady in the court of France, was of a noble family, and born at Paris in the year 1615; but rendered herſelf famous by her wit and gallantries. Her mother was a lady of exemplary piety; but her father early inſpired her with the love of pleaſure. Having loſt her parents at 14 years of age, and finding herſelf miſtreſs of her own actions, ſhe reſolved never to marry: ſhe had an income of 10,000 livres a-year; and, according to the leſſons ſhe had received from her father, drew up a plan of life and gallantry, which ſhe purſued till her death. Never delicate with reſpect to the number, but always in the choice, of her pleaſures, ſhe ſacrificed nothing to intereſt; but loved only while her taſte for it continued; and had among her admirers the greateſt lords of the court. But though ſhe was light in her amours, ſhe had many virtues.—She was conſtant in her friendſhip, faithful to what are called the *laws of honour*, of ſtrict veracity, diſintereſted, and more particularly remarkable for the exacteſt probity. Women of the moſt reſpectable characters were proud of the honour of having her for their friend; at her houſe was an aſſemblage of every thing moſt agreeable in the city and the court; and mothers were extremely deſirous of ſending their ſons to that ſchool of politeneſs and good taſte, that they might learn ſentiments of honour and probity, and thoſe other virtues that render men amiable in ſociety. But the illuſtrious Madame de Sevigné with great juſtneſs remarks in her letters, that this ſchool was dangerous to religion and the Chriſtian virtues; becauſe Ninon L'Enclos made uſe of ſeducing maxims, capable of depriving the mind of thoſe invaluable treaſures. Ninon was eſteemed beautiful even in old age; and is ſaid to have inſpired violent paſſions at 80. She died at Paris in 1705. This lady had ſeveral children; one of whom, named *Chevalier de Villiers*, occaſioned much diſcourſe by the tragical manner in which he ended his life. He became in love with Ninon, without knowing that ſhe was his mother; and when he diſcovered the ſecret of his birth, ſtabbed himſelf in a fit of deſpair. There have been publiſhed the pretended Letters of Ninon L'Enclos to the Marquis de Sevigné.

NINTH, in muſic. See Interval.

NINUS, the firſt king of the Aſſyrians, was, it is ſaid, the ſon of Belus. It is added, that he enlarged Nineveh and Babylon; conquered Zoroaſter king of the Bactrians; married Semiramis of Aſcalon; ſubdued almoſt all Aſia; and died after a glorious reign of 52 years, about 1150 B. C.; but all theſe facts are uncertain. See Semiramis.

NIO, an iſland of the Archipelago, between Naxi to the north, Armago to the eaſt, Santerino to the ſouth, and Sikino to the weſt, and is about 35 miles in circumference. It is remarkable for nothing but Homer's tomb, which they pretend is in this iſland; for they affirm that he died here in his paſſage from Samos to Athens. The iſland is well cultivated, and not ſo ſteep as the other iſlands, and the wheat which it produces is excellent; but oil and wood are ſcarce. It is ſubject to the Turks. E. Long. 25. 53. N. Lat. 36. 35.

Niobe.

NIOBE, (fab. hiſt.) according to the fictions of the poets was the daughter of Tantalus, and wife of Amphion king of Thebes; by whom ſhe had ſeven ſons and as many daughters. Having become ſo proud of her fertility and high birth, as to prefer herſelf before Latona, and to ſlight the ſacrifices offered up by the Theban matrons to that goddeſs, Apollo and Diana, the children of Latona, reſented this contempt. The former ſlew the male children and the latter the female; upon which Niobe was ſtruck dumb with grief, and remained without ſenſation. Cicero is of opinion, that on this account the poets feigned her to be turned into ſtone.

The ſtory of Niobe is beautifully related in the ſixth book of the Metamorphoſes of Ovid. That poet thus deſcribes her transformation into ſtone.

> Widow'd and childleſs, lamentable ſtate!
> A doleful ſight, among the dead ſhe ſat;
> Harden'd with woes, a ſtatue of deſpair,
> To ev'ry breath of wind unmov'd her hair;
> Her cheek ſtill redd'ning, but its colour dead,
> Faded her eyes, and ſet within her head.
> No more her pliant tongue its motion keeps,
> But ſtands congeal'd within her frozen lips.
> Stagnate and dull, within her purple veins,
> Its current ſtopp'd, the lifeleſs blood remains.
> Her feet their uſual offices refuſe,
> Her arms and neck their graceful geſtures loſe:
> Action and life from every part are gone,
> And ev'n her entrails turn to ſolid ſtone.
> Yet ſtill ſhe weeps; and whirl'd by ſtormy winds,
> Borne thro' the air, her native country finds;
> There fix'd, ſhe ſtands upon a bleaky hill;
> There yet her marble cheeks eternal tears diſtil.

Niobe in this ſtatue is repreſented as in an ecſtacy of grief for the loſs of her offſpring, and about to be converted into ſtone herſelf. She appears as if deprived of all ſenſation by the exceſs of her ſorrow, and incapable either of ſhedding tears or of uttering any lamentations, as has been remarked by Cicero in the third book of his Tuſculan Queſtions. With her right hand ſhe claſps one of her little daughters, who throws herſelf into her boſom; which attitude equally ſhows the ardent affection of the mother, and expreſſes that natural confidence which children have in the protection of a parent. The whole is executed in ſuch a wonderful manner, that this, with the other ſtatues of her children, is reckoned by Pliny among the moſt beautiful works of antiquity: but he doubts to whom of the Grecian artiſts he ought to aſcribe the honour of them (A). We have no certain information at what period

---

(A) Par hæſitatio in templo Apollinis Soſiani, Niobem cum liberis morientem, Scopas an Praxiteles fecerit.

riod this celebrated work was transported from Greece to Rome, nor do we know where it was first erected. Flaminius Vacca only says, that all these statues were found in his time not far from the gate of St John, and that they were afterwards placed by the grand duke Ferdinand in the gardens of the Villa de Medici near Rome.—An ingenious and entertaining traveller (Dr Moore), speaking of the statue of Niobe, says, "The author of Niobe has had the judgment not to exhibit all the distress which he might have placed in her countenance. This consummate artist was afraid of disturbing her features too much, knowing full well that the point where he was to expect most sympathy was there, where distress co-operated with beauty, and where *our pity met our love.* Had he sought it one step farther in *expression,* he had lost it."

In the following epigram this statue is ascribed to Praxiteles:

Εκ ζωης με Θεοι θεν σκιλιθον. Εκ δε λιθοιο
Ζωην Πραξιτελης εμπαλιν ειργασατο.

While for my children's fate I vainly mourn'd,
The angry gods to massy stone me turn'd;
Praxiteles a nobler feat has done,
He made me live again from being stone.

The author of this epigram, which is to be found in the 4th book of the *Anthology,* is unknown. Scaliger the father, in his *Farrago Epigrammatum,* p. 172. ascribes it to Callimachus, but this appears to be only conjecture. Cœlius Calcagninus has made a happy [illegible] of it into Latin.

[illegible] in lapidem verterunt numina; sed me
[illegible] vivam reddidit ex lapide.

[illegible] the following French version of it will [illegible] happy:

De vive que j'étois, les Dieux
[illegible] en pierre massive;
Praxitele a fait beaucoup mieux,
De pierre il m'a sçû rendre vive.

NIPHON, the largest of the Japan islands, being 600 miles long and 100 broad. See Japan.

NIPPERS, in the manege, are four teeth in the fore part of a horse's mouth, two in the upper, and two in the lower jaw. A horse puts them forth between the second and third year.

NIPPLES, in Anatomy. See there, N° 112.

NIPPLE-wort, in Botany. See Lapsana.

NISAN, a month of the Hebrews, answering to our March, and which sometimes takes from February or April, according to the course of the moon. It was the first month of the sacred year, at the coming out of Egypt (Exod. xii. 2.), and it was the seventh month of the civil year. By Moses it is called Abib. The name Nisan is only since the time of Ezra, and the return from the captivity of Babylon.

On the first day of this month the Jews fasted for the death of the children of Aaron (Lev. x. 1, 2, 3.) On the tenth day was celebrated a fast for the death of Miriam the sister of Moses; and every one provided himself with a lamb for the passover. On this day the Israelites passed over Jordan under the conduct of Joshua (iv. 19.) On the fourteenth day in the evening they sacrificed the paschal lamb; and the day following, being the [illegible], was held the solemn passover (Exod. xii. 18. &c.) The sixteenth they offered the sheaf of the ears of barley as the first fruits of the harvest of that year (Levit. xxiii. 9. &c.) The twenty-first was the octave of the passover, which was solemnized with particular ceremonies. The twenty-sixth the Jews fasted in memory of the death of Joshua. On this day they began their prayers to obtain the rains of the spring. On the twenty-ninth they called to mind the fall of the walls of Jericho.

NISI prius, in law, a judicial writ which lies in cases where the jury being impannelled and returned before the justices of the bank, one of the parties requests to have such a writ for the ease of the country, in order that the trial may come before the justices in the same county on their coming thither. The purport of a writ of *nisi prius* is, that the sheriff is thereby commanded to bring to Westminster the men impannelled, at a certain day, before the justices, "*nisi prius justiciarii domini regis ad assisas capiendas venerint.*"

NISIBIS (anc. geog.), a city both very ancient, very noble, and of very considerable strength, situated in a district called *Mygdonia,* in the north of Mesopotamia, towards the Tigris, from which it is distant two days journey. Some ascribe its origin to Nimrod, and suppose it to be the *Achad* of Moses. The Macedonians called it *Antiochia of Mygdonia* (Plutarch); situated at the foot of Mount Masius (Strabo). It was the Roman bulwark against the Parthians and Persians. It sustained three memorable sieges against the power of Sapor, A. D. 338, 346, and 350; but the emperor Jovianus, by an ignominious peace, delivered it up to the Persians, A. D. 363.——A colony called *Septimia Nisibitana.*——Another *Nisibis,* of Aria, (Ptolemy), near the lake Arias.

Mr Ives, who passed through this place in 1758, tells us, that "it looked pretty at a distance, being seated on a considerable eminence, at the foot of which runs a river, formerly called the *Mygdonius,* with a stone bridge of eleven arches built over it. Just by the river, at the foot of the hill, or hills (for the town is seated on two), begin the ruins of a once more flourishing place, which reach quite up to the present town. From every part of this place the most delightful prospects would appear, were the soil but properly cultivated and planted; but instead of those extensive woods of fruit trees, which Rawolf speaks of as growing near the town, not above thirty or forty straggling trees of any kind can be perceived; and instead of that great extent of arable land on which he dwells so much, a very inconsiderable number of acres are now remaining. The town itself is despicable, the streets extremely narrow, and the houses, even those which are of stone, are mean. It suffered grievously by the famine of 1757, losing almost all its inhabitants either by death or desertion. The streets presented many miserable objects, who greedily devoured rinds of cucumbers, and every other refuse article of food thrown out into the highway. Here the price of bread had risen near 4000 per cent. within the last 14 years.

NISMES, an ancient, large, and flourishing town of France, in Languedoc, with a bishop's see, and an academy. It has such a number of manufactures of

Nobility.

heirs according to the limitation thereof, though he never himſelf makes uſe of it. Yet it is frequent to call up the eldeſt ſon of a peer to the houſe of lords by writ of ſummons, in the name of his father's barony: becauſe in that caſe there is no danger of his children's loſing the nobility in caſe he never takes his ſeat; for they will ſucceed to their grandfather. Creation by writ has alſo one advantage over that by patent; for a perſon created by writ holds the dignity to him and his heirs, without any words to that purport in the writ; but in letters patent there muſt be words to direct the inheritance, elſe the dignity endures only to the grantee for life. For a man or woman may be created noble for their [illegible] lives, and the dignity not deſcend to their heirs at all, or deſcend only to ſome particular heirs: as where a peerage is limited to a man and the heirs male of his body by Elizabeth his preſent lady, and not to ſuch heirs by any former or future wife.

2. Let us next take a view of a few of the principal incidents attending the nobility,—excluſive of their capacity as members of parliament, and as hereditary counſellors of the crown, for both which we refer to the articles LORDS and PARLIAMENT. And firſt we muſt obſerve, that in criminal caſes a nobleman ſhall be tried by his peers. The great are always obnoxious to popular envy: were they to be judged by the people, they might be in danger from the prejudice of their judges; and would moreover be deprived of the privilege of the meaneſt ſubjects, that of being tried by their equals, which is ſecured to all the realm by magna charta, c. 29. It is ſaid, that this does not extend to biſhops; who, though they are lords of parliament, and ſit there by virtue of their baronies which they hold *jure eccleſiæ*, yet are not ennobled in blood, and conſequently not peers with the nobility. As to peereſſes, no proviſion was made for their trial when accuſed of treaſon or felony, till after Eleanor ducheſs of Glouceſter, wife to the lord protector, had been accuſed of treaſon, and found guilty of witchcraft, in an eccleſiaſtical ſynod, through the intrigues of Cardinal Beaufort. This very extraordinary trial gave occaſion to a ſpecial ſtatute, 20 Hen. VI. c. 9. which enacts, that peereſſes, either in their own right or by marriage, ſhall be tried before the ſame judicature as peers of the realm. If a woman, noble in her own right, marries a commoner, ſhe ſtill remains noble, and ſhall be tried by her peers: but if ſhe be only noble by marriage, then by a ſecond marriage with a commoner ſhe loſes her dignity; for as by marriage it is gained, by marriage it is alſo loſt. Yet if a ducheſs dowager marries a baron, ſhe continues a ducheſs ſtill: for all the nobility are *pares*, and therefore it is no degradation. A peer or peereſs (either in her own right or by marriage) cannot be arreſted in civil caſes: and they have alſo many peculiar privileges annexed to their peerage in the courſe of judicial proceedings. A peer ſitting in judgment, gives not his verdict upon oath, like an ordinary juryman, but upon his honour; he anſwers alſo to bills in chancery upon his honour, and not upon his oath: but, when he is examined as a witneſs either in civil or criminal caſes, he muſt be ſworn; for the reſpect which the law ſhows to the honour of a peer does not extend ſo far as to overturn a ſettled maxim, that *in judicio non creditur niſi juratis*. The honour of peers is however ſo highly tendered by the law, that it is much more penal to ſpread falſe reports of them, and certain other great officers of the realm, than of other men: ſcandal againſt them being called by the peculiar name of *ſcandalum magnatum*, and ſubjected to peculiar puniſhment by divers ancient ſtatutes.

Nobility, Noble.

A peer cannot loſe his nobility but by death or attainder; though there was an inſtance, in the reign of Edward IV. of [illegible] degradation of George Nevile duke of Bedford b[illegible] of parliament, on account of his poverty, which rendered him unable to ſupport his dignity. But this is a ſingular inſtance: which ſerves at the ſame time, by having happened, to ſhow the power of parliament; and, by having happened but once, to ſhow how tender the parliament hath been in exerting ſo high a power. It hath been ſaid indeed, that if a baron waſtes his eſtate, ſo that he is not able to ſupport the degree, the king may degrade him: but it is expreſsly held by later authorities, that a peer cannot be degraded but by act of parliament.

Anton. Matthæus obſerves, that nobility, among the Romans, was a quite different thing from what it is among us. The nobles, among the Romans, were either thoſe raiſed to the magiſtrature, [illegible] deſcended from magiſtrates: there was no ſuch [illegible] as nobility by patent.

Bartoli ſays, that doctors, after they have held a profeſſor's chair in an univerſity for 20 years, become noble; and are entitled to all the rights of counts.

But this claim is not admitted [illegible] court, &c. though Bartoli's ſentiments be backed with thoſe of ſeveral other authors, particularly Chaſſanæus in his *Conſuetudin. Burgundiæ*, *Boyer ſur la Coutume de Berry*; *Faber C. de Dig. Def.* 9. &c. which laſt, however, reſtrains Bartoli's rule to doctors in law, and princes phyſicians.

By an edict of the French king in 1669, it is declared, that trade ſhall not derogate from nobility, provided the perſon do not ſell by retail.

In Bretagne, by ancient cuſtom, a nobleman loſes nothing by trading even in retail: but he reaſſumes all his rights as ſoon as he ceaſes traffic, his nobility having ſlept all the time.

In Germany, a woman, not noble by birth, doth not become, *v. gr.* a counteſs or baroneſs by marrying a count or baron: a lady of the higher degree indeed becomes a princeſs by marrying a prince; but this does not hold of a lady of the lower nobility.

On the coaſt of Malabar, children are only capable of being noble by the mother's ſide; it being allowed them to take as many huſbands as they pleaſe, and to quit them whenever they think good.

NOBLE, *Nobilis*, a perſon who has a privilege which raiſes him above a commoner or peaſant, either by birth, by office, or by patent from his prince. The word comes from the Latin *nobilis*; formed from the ancient *noſcibilis*, "diſtinguiſhable, remarkable."

In England, the word *noble* is of a narower import than in other countries; being confined to perſons above the degree of knights; whereas, abroad, it comprehends not only knights, but what we ſimply call *gentlemen*. The nobles of England are alſo called *pares regni*, as being *nobilitatis pares*, though *gradu impares*.

The Venetian *nobleſſe* is famous: it is in this that the ſovereignty of the ſtate reſides. It is divided into three claſſes. The firſt only comprehends 24 families. The ſecond includes the deſcendants of all thoſe who were entered in the Golden Book, in 1289, and deſtined to govern the ſtate, which then began to be ariſtocratic. The third conſiſts of ſuch as have bought the dignity of noble Venetians. This laſt claſs is only admitted to the inferior employs; the two former to all indifferently. The title of *noble Venetians* is ſometimes alſo given to foreign kings, princes, [illegible]

Nobles, among the Roman[illegible] ſuch as had the *jus imaginum*, or the right of uſing the pictures or ſtatues of their anceſtors; a right which was allowed only to thoſe whoſe anceſtors had borne ſome *curule* office, that is, had been *curule ædile, cenſor, prætor*, or *conſul*. For a long time, none but the *patricii* were the *nobiles*, becauſe no perſon but of that ſuperior rank could bear any *curule* office; hence in Livy, Salluſt, &c. *nobilitas* is uſed to ſignify the patrician order, and ſo oppoſed to *plebs*. To make the true meaning of *nobiles* ſtill more clear, let it be obſerved, that the Roman people were divided into *nobiles, novi*, and *ignobiles*. *Nobiles* were they who had the pictures, &c. of their anceſtors: *novi* were ſuch as had only their own; *ignobiles* were ſuch as had neither. See *Jus Imaginis*.

The Roman nobility, by way of diſtinction, wore a half moon upon their ſhoes, eſpecially thoſe of patrician rank.

The Grecian nobility were called Ευπατρίδαι, as being deſcended from thoſe old heroic anceſtors ſo famous in hiſtory. Such were the *Praxiergidæ, Etrobutidæ, Alcmæonidæ*, &c. all which had many privileges annexed to their quality; amongſt which was this, that they wore graſhoppers in their hair as a badge of nobility.

Noble, a money of account containing ſix ſhillings and eight pence.

The noble was anciently a real coin ſtruck in the reign of Edward III. and then called the *penny of gold*; but it was afterwards called a *roſe-noble*, from its being ſtamped with a roſe: it was current at 6s. 8d.

NOCERA, a town in Italy, in the dominions of the king of Naples and Sicily, or, as he is more commonly called, the king of the Two Sicilies. It is an epiſcopal city, but might with greater propriety be ſtyled a cluſter of villages; its ſeveral parts being extended along the foot of the mountains, form the Città Sotana, or low town; and the biſhop's palace, together with ſome convents embowered in cypreſs groves, cover the peak of a ſingle hill in a very picturesque manner, and compoſe the Città Soprana.

Nocera (A), it is reported, contains near 30,000 inhabitants; they are diſperſed in forty patches of habitation. Their houſes are conſtructed of two kinds of ſtone: the common walls are built with yellow tufa dug out of the hills that lie about a mile to the eaſt of the town; which ſtone ſeems unqueſtionably to have been formed by a conſolidation of ſubſtances thrown out of Veſuvius; becauſe, on opening theſe quarries, the workmen have frequently diſcovered tombs, vaſes, and coins locked up in the body of the ſtony ſtratum. The caſes of their doors and windows are made of a black ſtone drawn from the hill of Fiano, two miles to the north: it lies eight feet below the ſurface, in a bed or vein 140 feet thick, reſting upon a baſe of ſand. This ſeems evidently to be a ſtream of lava congealed.

Nocera is a place of very conſiderable antiquity: in the 13th century is was called de Pagani, to diſtinguiſh it from a city in Umbria of a ſimilar name; this addition was in alluſion to a colony of Saracens which Frederick of Suabia brought from Sicily, and ſettled here, that they might be out of the way of their dangerous connexions with Africa: hence Nocera has often been confounded with Lucera by the negligent or ignorant chroniclers of the ſucceeding ages. The moſt remarkable event that occurs in its hiſtory is the ſiege of its caſtle, A. D. 1384. E. Long. 12. 55. N. Lat. 43. 2.

Terra Noceriana, *Earth of Nocera*, in the materia medica, a ſpecies of bole, remarkably heavy, of a grayiſh-white colour, of an inſipid taſte, and generally with ſome particles in it which grit between the teeth. It is much eſteemed by the Italians as a remedy for venomous bites, and in fevers; but, excepting as an abſorbent and aſtringent, no dependence is to be had on it.

NOCTAMBULI, Noctambulones, or *Night-walkers*; a term of equal import with *ſomnambuli*, applied to perſons who have a habit of riſing and walking about in their ſleep. The word is a compound of the Latin *nox*, "night," and *ambulo*, "I walk."

Schenkius, Horſtius, Clauderus, and Hildanus, who have wrote of ſleep, give us divers unhappy hiſtories of ſuch noctambuli. When the diſeaſe is moderate, the perſons affected with it only repeat the actions of the day on getting out of bed, and go quietly to the places they frequented at other times; but thoſe who have it in the moſt violent degree, go up to dangerous places, and do things which would terrify them to think of when they are awake. Theſe are by ſome called *lunatic* night-walkers, becauſe fits are obſerved to return with the moſt frequency and violence at the changes of the moon.—For the cure ſome recommend purging and a cooling regimen: others are of opinion that the beſt method is to place a veſſel of water at the patient's bedſide in ſuch a manner that he will naturally ſtep into it when he gets out of bed; or if that ſhould fail, a perſon ſhould ſit up to watch and beat him every time it happens. See Sleep-walkers, or Somnambuli.

NOCTILUCA, a ſpecies of phoſphorus, ſo called becauſe it ſhines in the dark without any light being thrown upon it: ſuch is the phoſphorus made of urine.

NOCTURNAL, ſomething relating to the night, in contradiſtinction to diurnal.

Nocturnal, *Nocturlabium*, an inſtrument chiefly uſed at ſea, to take the altitude or depreſſion of ſome ſtars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemiſpheres, or planiſpheres,

(A) Anciently, Nuceria Alphaterna, a word of unknown etymology. It was a Roman colony, and had its mint.

Num. Nucerin.

1. Caput virile imberbe—Equus ſtans capite reflexo inter crura. A . . IN . .

on the plane of the equinoctial. Thoſe commonly in uſe among ſeamen are two; the one adapted to the polar ſtar, and the firſt of the guards of the Little Bear; the other to the pole ſtar, and the pointers of the Great Bear.

This inſtrument conſiſts of two circular plates, applied to each other. The greater, which has a handle to hold the inſtrument, is about 2½ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month ſubdivided into every fifth day; and ſo as that the middle of the handle correſponds to that day of the year wherein the ſtar here regarded has the ſame right aſcenſion with the ſun. If the inſtrument be fitted for two ſtars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour ſubdivided into quarters. Theſe twenty-four hours are noted by twenty-four teeth to be told in the night. Thoſe at the hour 12 are diſtinguiſhed by their length. In the centre of the two circular plates is adjuſted a long index, moveable upon the upper plate; and the three pieces, viz. the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the ſtar is to be obſerved. Plate CCCXLVI

To uſe the nocturnal, turn the upper plate till the long tooth, marked 12, be againſt the day of the month on the under plate; then, bringing the inſtrument near the eye, ſuſpend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole ſtar through the hole of the centre, turn the index about, till, by the edge coming from the centre, you ſee the bright ſtar or guard of the Little Bear, (if the inſtrument be fitted to that ſtar): then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle: which may be known without a light, by counting the teeth from the longeſt, which is for the hour 12.

NOD, or the *Land of Nod*. It was to this country that Cain withdrew after his fratricide, (Gen. iv. 16.) The Septuagint, as well as Joſephus, read *Naid* inſtead of *Nod*, and have taken it for the name of a place. It is not eaſily known what country this was, unleſs perhaps it was the country of Nyſe or Nyſea, towards Hyrcania. St Jerome and the Chaldee interpreters have taken the word Nod in the ſenſe of an appellative, for *vagabond* or *fugitive*; "He dwelt a fugitive in the land." But the Hebrew reads, "He dwelt in the land of Nod." (Gen. iv. 16.)

NODAB, a country bordering upon Iturea and Idumæa, but now unknown. We read in the Chronicles, that the tribe of Reuben, aſſiſted by thoſe of Gad and Manaſſeh, had a war againſt the Hagarites, the Jeturites, and the people of Nephiſh, and of Nodab, in which the Iſraelites had the advantage. 1 Chr. v. 19. But the time and the other particulars of this war are unknown.

NODATED HYPERBOLA, a name given by Sir Iſaac Newton to a kind of hyperbola, which, by turning round, decuſſates or croſſes itſelf.

NODDY. See STERNA.

NODE, a tumour ariſing on the bones, and uſually proceeding from ſome venereal cauſe; being much the ſame with what is otherwiſe called *exoſtoſis*.

NODES, in aſtronomy, the two points where the orbit of a planet interſects the ecliptic.

Such are the two points C and D; of which the node C, where the planet aſcends northward above the plane of the ecliptic, is called the *aſcending node*, or the *dragon's head*, and is marked thus ☊. The other node D, where the planet deſcends to the ſouth, is called the *deſcending node*, or the *dragon's tail*, marked thus ☋. Plate CCCXLVI N° 1.

The line C[illegible]herein the two circles CEDF and CGDH inte[illegible] called the *line of nodes*. It appears from ob[illegible]tion, that the line of the nodes of all the planets conſtantly changes its place, and ſhifts its ſituation from eaſt to weſt, contrary to the order of the ſigns; and that the line of the moon's nodes, by a retrograde motion, finiſhes its circulation in the compaſs of 19 years; after which time, either of the nodes having receded from any point of the ecliptic, returns to the ſame again; and when the moon is in the node, ſhe is alſo ſeen in the ecliptic. If the line of nodes were immoveable, that is, if it had no other motion than that whereby it is carried round the ſun, it would always look to the ſame point of the ecliptic, or would keep parallel to itſelf, as the axis of the earth does.

From what hath been ſaid, it is evident, that the moon can never be obſerved preciſely in the ecliptic, but twice in every period; that is, when ſhe enters the nodes. When ſhe is at her greateſt diſtance from the nodes, viz. in the points E, F, ſhe is ſaid to be in her limits.

The moon muſt be in or near one of the nodes, when there is an eclipſe of the ſun or moon.

To make the foregoing account of the motion of the moon's nodes ſtill clearer, let the plane of N° 2. *ibid.* repreſent that of the ecliptic, S the ſun, T the centre of the earth, L the moon in her orbit D N *d n*. N *n* is the line of the nodes paſſing between the quadrature Q and the moon's place L, in her laſt quarter. Let now LP, or any part LS, repreſent the exceſs of the ſun's action at T; and this being reſolved into the force LR, perpendicular to the plane of the moon's orbit, and PR parallel to it, it is the former only that has any effect to alter the poſition of the orbit, and in this it is wholly exerted. Its effect is twofold: 1. It diminiſhes its inclination by a motion which we may conceive as performed round the diameter D *d*, to which L T is perpendicular. 2. Being compounded with the moon's tangential motion at L, it gives it an intermediate direction L *t*, through which and the centre a plane being drawn, muſt meet the ecliptic nearer the conjunction C than before.

NODUS, or node, in dialling, a certain point or pole in the gnomon of a dial, by the ſhadow or light whereof either the hour of the day in dials without furniture, or the parallels of the ſun's declination, and his place in the ecliptic, &c. in dials with furniture, are ſhown. See DIALLING.

NOEOMAGUS LEXUVIORUM, (Ptol.); thought to be the *Civitas Lexoviorum* of the lower age. Now *Liſieux*, a city in Normandy.—Another of the *Tricaſtini*; a town of Gallia Narbonenſis; thought to be *S. Pol. de Trois Châteaux*, ſix miles to the weſt of Nyons in Dauphiné.

NOETIANS, in church hiſtory, Chriſtian heretics in the third century, followers of Noetius, a philoſopher of Epheſus, who pretended that he was another Moſes ſent by God, and that his brother was a new Aaron. His hereſy conſiſted in affirming that there was but one perſon in the Godhead; and that the Word and the Holy Spirit were but external denominations given to God in conſequence of different operations: that, as Creator, he is called *Father*; as Incarnate, *Son*; and as deſcending on the apoſtles, *Holy Ghoſt*.

NOLA, a very ancient city, [illegible] populous and ſtrong, ſituated in a plain to the [illegible] of Veſuvius, in Campania, ſaid to be built [illegible] Chalcidians; (Juſtin, Silius Italicus); according to others, by the Tuſcans. At this place Hannibal met with the firſt check by Marcellus. Veſpaſian added the appellation *Auguſta Colonia*, (Frontinus). At this place, or in its neighbourhood, Auguſtus is ſaid to have expired. It is alſo ſaid that bells were firſt invented there in the beginning of the 5th century; hence their Latin names *Nola* or *Campanæ*. It retains its old name to this day, but it hath vaſtly fallen ſhort of its ancient ſplendour. A town of the kingdom of Naples. E. Long. 15. N. Lat. 41. 5.

NOLANA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 41ſt order, *Aſperifoliæ*. The corolla is campanulated; the ſtyle ſituated betwixt the germens; the ſeeds are bilocular, and reſemble berries.

NOLLE PROSEQUI, is where a plaintiff in an action does not declare in a reaſonable time; in which caſe it is uſual for the defendant's attorney to enter a rule for the plaintiff to declare, after which a *non proſ.* may be entered. A *nolle proſequi* is eſteemed a voluntary confeſſion, that the plaintiff has no cauſe of action; and therefore if a plaintiff enters his *nolle proſequi*, he ſhall be amerced; and if an informer cauſe the ſame to be entered, the defendant ſhall have coſts.

NOLLET (Jean Antoine), a deacon, licentiate in theology, preceptor to the *Enfans de France* for phyſics and natural hiſtory, regius profeſſor of phyſics in the college of Navarre, member of the Academy of Sciences at Paris, of the Royal Society of London, of the Inſtitution of Bologna, and of the Academy of Sciences of Erfort; was born at Pimbré, in the dioceſe of Noyon, on the 17th of November 1700, of reſpectable but not wealthy parents. To make up the want of riches, they determined to give their ſon a good education. They ſent him to the college of Clermont in Beauvoiſis, and afterwards to Beauvais, there to finiſh his introductory ſtudies. The progreſs which he made in the different claſſes, determined them to ſend him to ſtudy philoſophy at Paris. Thenceforward they intended him for the clerical order; and they conſidered the ſtrictneſs and purity of his morals, together with his unwearied application to ſtudy, as ſufficient proofs of his vocation. The young Nollet yielded without reluctance to the wiſhes of his parents. As ſoon as he was capable of ſhowing an inclination for any thing, he had diſcovered a taſte for phyſics; but this was not become his ruling paſſion; he therefore ſacrificed it to the ſtudy of ſcholaſtic divinity, to which he wholly dedicated himſelf during his time of probation in 1728. No ſooner had he been inveſted with the deaconſhip, than he ſolicited and obtained a licenſe to preach. This new occupation, however, did not make him entirely loſe ſight of thoſe ſtudies which had firſt engaged his attention. They inſenſibly began to occupy a greater portion of his time, which was now more equally divided between theology and the ſciences. The latter, however, prevailed; and thenceforth he entered into the ſtudy of phyſics with an ardour which was only increaſed by that kind of privation to which he had been long ſubject. He was received into the Society of Arts, eſtabliſhed at Paris under the patronage of the late count de Clermont. In 1730, the Abbé Nollet was engaged in a work conjunctly with Reaumur and du Fay of the Academy of Sciences. In 1734, he went to London in company with M. M. du Fay, du Hamel, and de Juſſieu. His merit procured him a place in the Royal Society without any ſolicitation. Two years after, he went to Holland, where he formed an intimate connexion with Deſaguliers, Graveſande, and Muſchenbroeck. On his return to Paris, he reſumed the courſe of experimental phyſics which he had begun in 1735, and which he continued till 1760. Theſe courſes of phyſics firſt ſuggeſted the idea of particular courſes in other branches of ſcience, ſuch as in chemiſtry, anatomy, natural hiſtory, &c. In 1738, the count de Maurepas prevailed on the cardinal Fleury to eſtabliſh a public claſs for experimental phyſics; and the Abbé Nollet was appointed the firſt profeſſor. In the beginning of the year 1739, he was admitted a member of the Royal Academy of Sciences; and in the month of April following, the king of Sardinia intending to eſtabliſh a profeſſorſhip of phyſics at Turin, invited the Abbé Nollet into his dominions. From thence he travelled into Italy. In 1744, he was honoured with an invitation to Verſailles, to inſtruct the dauphin in experimental philoſophy; the king and royal family were often preſent at his lectures. The qualities as well of his underſtanding as of his heart gained him the eſteem and confidence of his pupil. Going one day in ſtate to Paris, he cauſed intimation to be made that he was to dine at the Thuilleries. M. Nollet having gone thither to pay his court, the dauphin no ſooner perceived him, than he had the goodneſs to ſay, "Binet has the advantage of me, he has been at your houſe." Till the period of his death, this prince ſhowed marks of the ſtrongeſt attachment and favour for this ingenious philoſopher. He would have wiſhed that he had been a little more attentive to the improvement of his fortune. He prevailed upon him to go and pay court to a man in power, whoſe patronage might have been of ſervice to him. The Abbé Nollet accordingly waited upon the placemen, and made him a preſent of his works. "I never read any works of that kind," ſaid the patron coldly, and caſting a look at the volumes before him. "Sir (replied the Abbé), will you allow them to remain in your antichamber? There perhaps there may be found men of genius who will read them with pleaſure." In the month of April 1749, he made a grand tour into Italy, being ſent thither for the purpoſe of making obſervations. At Turin, Venice, and Bologna, the Abbé Nollet appeared as a deputy from the philoſophers of the reſt of Europe. During his ſhort ſtay in Italy, the wonders of electricity were not the only object of his reſearches; every part of phyſics, the arts agriculture, &c. came equally under his notice. Upon his return through Turin, the king of Sardinia, always truly ſenſible of his merit, offered him the order of Saint Maurice, which he did not think proper to accept without his ſovereign's permiſſion. In 1753 the king inſtituted a claſs of experimental philoſophy in the royal college of Navarre, and appointed the Abbé Nollet profeſſor. In 1757, he received from the king a brevet appointing him preceptor in phyſics and natural hiſtory to the *Enfans de France*. In the month of Auguſt, the ſame year, he was appointed profeſſor of experimental philoſophy in the ſchool of Artillery, at that time eſtabliſhed at la Fere. In the month of November following, he was admitted as a penſionary of the Royal Academy of Sciences. M. de Cremillo, director general of artillery and fortification, having founded a claſs of experimental philoſophy at Mezieres in 1761, the Abbé Nollet was appointed profeſſor. This celebrated and laborious philoſopher, who has rendered the moſt important ſervices to phyſics by the diſcoveries with which he has enriched every branch of this ſcience, but particularly electricity, died at Paris on the 25th of April 1770, aged 70; much regretted by the literary world, and by his friends, of whom his gentle character and beneficent heart had procured him a great number. He often retired from the gay and ſplendid ſocieties of Paris, to give aſſiſtance to his relations, who were by no means in affluent circumſtances. His works are, 1. Several papers inſerted in the memoirs of the Academy of Sciences; among which one on the Hearing of Fiſhes is particularly valuable. 2. *Leçons de Phyſique Experimentale*, 6 vols. 12mo; a book well compoſed, and uniting pleaſure with inſtruction. 3. *Recueil de Lettres ſur l'Electricité*, 3 vols. 12mo, 1753. 4. *Eſſai ſur l'Electricité des corps*, 1 vol. 12mo. 5. *Recherches ſur les cauſes particulieres des Phenoménes Electriques*, one vol. 12mo. 6. *L'Andes experiences*, 3 vols. 12mo, with figures, 1770.

NOMADES, a name given, in antiquity, to ſeveral nations, whoſe whole occupation was to feed and tend their flocks; and who had no fixed place of abode, but were conſtantly ſhifting, according to the conveniences of paſturage.—The word comes from the Greek νεμω, *paſco*, "I feed."

The moſt celebrated among the Nomades were thoſe of Africa, who inhabited between Africa properly ſo called, to the eaſt, and Mauritania to the weſt. They are alſo called *Numidæ* or *Numidians*.—Salluſt ſays, they were a colony of Perſians brought into Africa with Hercules.

The Nomades of Aſia inhabited the coaſts of the Caſpian ſea. The Nomades of Scythia were the inhabitants of Little Tartary; who ſtill retain the ancient manner of living.

NOMARCHA, in antiquity, the governor or commander of a nome, or nomos.—Egypt was anciently divided into ſeveral regions or quarters, called *nomes*, from the Greek νομος, taken in the ſenſe of a diviſion; and the officer who had the adminiſtration of each *nome* or *nomos*, from the king, was called *nomarcha*, from νομος and αρχη "command."

NOMBRE-DE-DIOS, a town of Mexico, in the province of Darien, a little to the eaſtward of Porto-Bello. It was formerly a famous place; but it is now abandoned, on account of its unhealthy ſituation. W. Long. 78. 35. N. Lat. 9. 45.

NOMBRIL POINT, in heraldry, is the next below the feſs point, or the very centre of the eſcutcheon.

Suppoſing the eſcutcheon divided into two equal parts below the feſs, the firſt of theſe diviſions is the nombril; and the lower the baſe.

NOME, or NAME, in algebra, denotes any quantity with a ſign prefixed or added to it, whereby it is connected wi[illegible] other quantity, upon which the whole becom[illegible]mial, trinomial, or the like. See ALGEBRA.

NOMENCLATOR, in Roman antiquity, was uſually a ſlave who attended upon perſons that ſtood candidates for offices, and prompted or ſuggeſted to them the names of all the citizens they met, that they might court them and call them by their names, which among that people was the higheſt piece of civility.

NOMENCLATORS, among the botanical authors, are thoſe who have employed their labours about ſettling and adjuſting the right names, ſynonymes, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, NOMENCLATURA, a catalogue of ſeveral of the more uſual words in any language, with their ſignifications, compiled in order to facilitate the uſe of ſuch words to thoſe who are to learn the tongue: ſuch are our Latin, Greek, French, &c. Nomenclatures.

The chemical nomenclature has within theſe few years undergone a total change: we have given a table exhibiting theſe new names facing page 598 of Volume IV. At that time we were not convinced of the propriety of the new theory, nor was it poſſible to foreſee that it would ſo ſoon obtain the approbation of the literary world. True philoſophy requires, however, that we ſhould readily change our opinions when we ſee ſufficient grounds, for *to err is human*. In conſequence of Lavoiſier's ſyſtem being now ſo univerſally adopted, it becomes neceſſary for us to explain his principles at more length than was thought proper before. This we think our duty, and it therefore ſhall be our endeavour, in ſome part of the work, to introduce a ſufficient analyſis of this celebrated and now almoſt univerſally adopted ſyſtem.

NOMENEY, a town in Germany, in the duchy of Lorrain, ſituated on the river Seille, 15 miles north of Nancy.

NOMINALS, or NOMINALISTS, a ſect of ſchool philoſophers, the diſciples and followers of Occam, or Ocham, an Engliſh Cordelier, in the 14th century. They were great dealers in words, whence they were vulgarly denominated *Word-ſellers*; but had the denomination of *Nominaliſts*, becauſe, in oppoſition to the *Realiſts*, they maintained, that words, and not things, were the object of dialectics.

This ſect had its firſt riſe towards the end of the 11th century, and pretended to follow Porphyry and Ariſtotle; but it was not till Ocham's time that they bore the name. The chief of this ſect, in the 11th century, was a perſon called *John*, who, on account of his logical ſubtilty, was called the *ſophiſt*; and his principal diſciples were Robert of Paris, Roſcelin of Compiegne, and Arnoul of Laon. At the beginning, the Nominals had the upper hand: but the Realiſts, though greatly divided among themſelves, were ſupported by men of great abilities; ſuch as Albertus Magnus, T. Aquinas, and Duns Scotus. The Nominal ſect became hereby into diſrepute; till William Occam, in the 14th century, again revived it, and filled France and Germany with the flame of diſputation. Having joined the party of the Franciſcan monks, who ſtrenuouſly oppoſed John XXII. that pope himſelf, and his ſucceſſors after him, left no means untried to extirpate the philoſophy of the Nominaliſts, which was deemed highly prejud[illegible] the intereſts of the church: and hence it wa[illegible] in the year 1339, the univerſity of Paris, by [illegible] public edict, ſolemnly condemned and prohibited the philoſophy of Occam, which was that of the Nominaliſts. The conſequence was, that the Nominaliſts flouriſhed more than ever. In the 15th century, the controverſy was continued with more vigour and animoſity than before; and the diſputants were not content with uſing merely the force of eloquence, but had frequently recourſe to more hoſtile and dangerous weapons; and battles were the conſequence of a philoſophical queſtion, which neither ſide underſtood. In moſt places, however, the Realiſts maintained a manifeſt ſuperiority over the Nominaliſts. While the famous Gerſon, and the moſt eminent of his diſciples were living, the Nominaliſts were in high eſteem and credit in the univerſity of Paris. But upon the death of theſe patrons, the face of things was much changed to their diſadvantage. In the year 1473, Louis XI. by the inſtigation of his confeſſor, the biſhop of Avranches, iſſued out a ſevere edict againſt the doctrines of the Nominaliſts, and ordered all their writings to be ſeized and ſecured, that they might not be read by the people: but the ſame monarch mitigated this edict the year following, and permitted ſome of the books of that ſect to be delivered from their confinement. In the year 1481, he not only granted a full liberty to the Nominaliſts and their writings, but alſo reſtored that philoſophical ſect to its former authority and luſtre in the univerſity.

The Nominaliſts were the founders of the univerſity of Leipſic: and there are many yet abroad who pique themſelves on being Nominals.

The Nominals, with the Stoics, admit the formal conceptions or ideas of things, as the ſubject and foundation of univerſality: but to this they add names, which repreſent and ſignify, after the ſame univocal manner, and without any diſtinction, a great variety of ſingle things alike in genus and ſpecies.

Whence it is that they are called *Nominals*; as pretending, that to become learned, it is not enough to have juſt ideas of things, but it is likewiſe required to know the proper names of the genera and ſpecies of things, and to be able to expreſs them clearly and preciſely, without confuſion or ambiguity.

NOMINATIVE, in grammar, the firſt CASE of NOUNS which are declinable.

The ſimple poſition, or laying down of a noun, or name, is called the *nominative caſe*; yet it is not ſo properly a caſe, as the matter or ground whence the other caſes are to be formed, by the ſeveral changes and inflections given to this firſt termination. Its chief uſe is to be placed in diſcourſe before all verbs, as the ſubject of the propoſition or affirmation.

NONA, a city of Dalmatia, remarkable at preſent only for its ruins, which might furniſh abundant materials to gratify the curioſity of antiquaries; but indeed they are ſo buried by repeated devaſtations, to which that unhappy city has been expoſed, that rarely any veſtige of them appears above ground. "I went thither (ſays Fortis in his Travels), in hopes of finding ſomething worthy of notice, but was diſappointed. Nothing is to be ſeen that indicates the grandeur of the Roman times; neither are there any remains of barbarous magnificence, to put one in mind of the ages in which the kings of the Croat Slavi had their reſidence there. It lies on a ſmall iſland, ſurrounded by a harbour, which in former times was capable of receiving large ſhips; but is now become a fetid pool by means of a little muddy river that falls into it, after a courſe of about ſix miles through the rich abandoned fields of that diſtrict. The ancient inhabitants turned this water into another channel, and made it run through the valley of Draſnich into the ſea; and the remains of the bank raiſed by them for that purpoſe are ſtill to be ſeen. Notwithſtanding, however, the depopulation of this diſtrict, and the dreary ſituation of Nona in particular, the new inhabitants have not loſt courage; and animated by the privileges granted to them by the moſt ſerene republic, are endeavouring to bring the population and agriculture once more into a flouriſhing ſtate. Proper drains for the water would not only render that rich territory habitable, but moreover very fertile; and the brackiſh marſh that ſurrounds the walls of Nona is well calculated to ſupply a conſiderable quantity of fiſh, eſpecially eels. The government generouſly granted the inveſtiture to private perſons, who already draw no inconſiderable advantage from the fiſhing; and did they but adopt better methods, they might every year ſalt many thouſands of eels, which would greatly anſwer our internal commerce, and ſave at leaſt a part of the money that goes out of the country for foreign ſalt fiſh. To the left of the city of Nona, the walls of ſome ancient ruinous buildings appear; which probably in ancient times were ſituated on the main land, though now ſurrounded by water. The ſea forms a narrow channel in this place, which is eaſily fordable, and, at low water, the ſmalleſt boat can ſcarcely paſs."

NONAGE, in law, generally ſignifies all the time a perſon continues under the age of 21; but in a ſpecial ſenſe, it is all the time that a perſon is under the age of 14.

NON, CAPE, a promontory on the weſt coaſt of Africa, oppoſite to the Canary iſlands. W. Long. 12. 0. N. Lat. 44. 28.

NONCONFORMISTS, thoſe who refuſe to join the eſtabliſhed worſhip.

Blackſt. Comment.

Nonconformiſts, in England, are of two ſorts. Firſt, Such as abſent themſelves from divine worſhip in the eſtabliſhed church through total irreligion, and attend the ſervice of no other perſuaſion. Theſe, by the ſtat. 1 Eliz. c. 2. 23 Eliz. c. 1. and 3 Jac. I. c. 4. forfeit one ſhilling to the poor every Lord's day they ſo abſent themſelves, and 20l. to the king if they continue ſuch default for a month together. And if they keep any inmate thus irreligiouſly diſpoſed in their houſes, they forfeit 10l. *per* month.

The ſecond ſpecies of nonconformiſts are thoſe who offend through a miſtaken or perverſe zeal. Such

Nonconformiſts.

Blackſt. Comment.

were eſteemed, by the Engliſh laws enacted ſince the time of the Reformation, to be Papiſts and Proteſtant diſſenters: both of which were ſuppoſed to be equally ſchiſmatics, in not communicating with the national church; with this difference, that the Papiſts divided from it upon material, though erroneous, reaſons; but many of the diſſenters upon matters of indifference, or, in other words, for no reaſon at all. "Yet certainly (ſays Sir William Blackſtone) our anceſtors were miſtaken in their plans of compulſion and intolerance. The ſin of ſchiſm, as ſuch, is by no means the object of temporal coercion and puniſhment. If, through weakneſs of intellect, through miſdirected piety, through perverſeneſs and acerbity of temper, or (which is often the caſe) through a proſpect of ſecular advantage in herding with a party, men quarrel with the eccleſiaſtical eſtabliſhment, the civil magiſtrate has nothing to do with it; unleſs their tenets and practice are ſuch as threaten ruin or diſturbance to the ſtate. He is bound indeed to protect the eſtabliſhed church: and if this can be better effected by admitting none but its genuine members to offices of truſt and emolument, he is certainly at liberty ſo to do; the diſpoſal of offices being matter of favour and diſcretion. But this point being once ſecured, all perſecution for diverſity of opinions, however ridiculous or abſurd they may be, is contrary to every principle of ſound policy and civil freedom. The names and ſubordination of the clergy, the poſture of devotion, the materials and colour of the miniſter's garment, the joining in a known or unknown form of prayer, and other matters of the ſame kind, muſt be left to the option of every man's private judgment.

"With regard therefore to *Proteſtant diſſenters*, although the experience of their turbulent diſpoſition in former times occaſioned ſeveral diſabilities and reſtrictions (which I ſhall not undertake to juſtify) to be laid upon them by abundance of ſtatutes; yet at length the legiſlature, with a true ſpirit of magnanimity, extended that indulgence to theſe ſectaries, which they themſelves, when in power, had held to be countenancing ſchiſm, and denied to the church of England. The penalties are conditionally ſuſpended by the ſtatute 1 W. &. M. ſt. 1. c. 18. "for exempting their Majeſties Proteſtant ſubjects, diſſenting from the church of England, from the penalties of certain laws," commonly called the *toleration act;* which declares, that neither the laws above mentioned, nor the ſtatutes 1 Eliz. c. 2. § 14. 3 Jac. I. c. 4 & 5. nor any other penal laws made againſt Popiſh recuſants (except the teſt acts), ſhall extend to any diſſenters, other than Papiſts and ſuch as deny the Trinity: provided, 1. That they take the oaths of allegiance and ſupremacy, (or make a ſimilar affirmation, being Quakers), and ſubſcribe the declaration againſt Popery. 2. That they repair to ſome congregation certified to and regiſtered in the court of the biſhop or archdeacon, or at the county ſeſſions. 3. That the doors of ſuch meeting houſe ſhall be unlocked, unbarred, and unbolted; in default of which, the perſons meeting there are ſtill liable to all the penalties of the former acts. Diſſenting teachers, in order to be exempted from the penalties of the ſtatutes 13 and 14 Car. II. c. 4. 17 Car II. c. 2. and 22 Car. II. c. 1. are alſo to ſubſcribe the articles of religion mentioned in the ſtatute 13 Eliz. c. 12. (viz. thoſe which only concern the confeſſion of the true Chriſtian faith, and the doctrine of the ſacraments), with an expreſs exception of thoſe relating to the government and powers of the church, and to infant baptiſm. And by ſtatute 10 Ann. c. 2. this toleration is ratified and confirmed; and it is declared, that the ſaid act ſhall at all times be inviolably obſerved for the exempting ſuch Proteſtant diſſenters as are thereby intended from the pains and penalties therein mentioned. T[illegible] though the offence of nonconformity is by [illegible] univerſally abrogated, it is ſuſpended, and [illegible] to exiſt with regard to theſe Proteſtant diſſenters, during their compliance with the conditions impoſed by the act of toleration: and, under theſe conditions, all perſons, who will approve themſelves no Papiſts or oppugners of the Trinity, are left at full liberty to act as their conſciences ſhall direct them in the matter of religious worſhip. And if any perſon ſhall wilfully, maliciouſly, or contemptuouſly diſturb any congregation, aſſembled in any church or permitted meeting houſe, or ſhall miſuſe any preacher or teacher there, he ſhall (by virtue of the ſame ſtatute) be bound over to the ſeſſions of the peace, and forfeit 20l. But by ſtatute 5 Geo. I. c. 4. no mayor or principal magiſtrate muſt appear at any diſſenting meeting with the enſigns of his office, on pain of diſability to hold that or any other office: the legiſlature judging it a matter of propriety, that a mode of worſhip, ſet up in oppoſition to the national, when allowed to be exerciſed in peace, ſhould be exerciſed alſo with decency, gratitude, and humility. Neither doth the act of toleration extend to enervate thoſe clauſes of the ſtatutes 13 & 14 Car. II. c. 4. and 17 Car. II. c. 2. which prohibit (upon pain of fine and impriſonment) all perſons from teaching ſchool, unleſs they be licenſed by the ordinary, and ſubſcribe a declaration of conformity to the liturgy of the church, and reverently frequent divine ſervice *eſtabliſhed* by the laws of this kingdom.

Nonconformiſts.

"As to *Papiſts*, what has been ſaid of the Proteſtant diſſenters would hold equally ſtrong for a general toleration of them; provided their ſeparation was founded only upon difference of opinion in religion, and their principles did not alſo extend to a ſubverſion of the civil government. If once they could be brought to renounce the ſupremacy of the Pope, they might quietly enjoy their ſeven ſacraments; their purgatory, and auricular confeſſion; their worſhip of relicks and images; nay, even their tranſubſtantiation. But while they acknowledge a foreign power, ſuperior to the ſovereignty of the kingdom, they cannot complain if the laws of that kingdom will not treat them upon the footing of good ſubjects.

"The following are the laws that have been enacted againſt the Papiſts; who may be divided into three claſſes, perſons profeſſing Popery, Popiſh recuſants convict, and Popiſh prieſts. 1. Perſons profeſſing the Popiſh religion, beſides the former penalties for not frequenting their pariſh church, are diſabled from taking any lands either by deſcent or purchaſe, after 18 years of age, until they renounce their errors; they muſt at the age of 21 regiſter their eſtates before acquired, and all future conveyances and wills relating to them; they are incapable of preſenting to any advowſon, or granting to any other perſon any avoid-

Blackſt. Comment.

ance of the ſame; they may not keep or teach any ſchool, under pain of perpetual impriſonment; and, if they willingly ſay or hear maſs, they forfeit the one 200, the other 100 merks, and each ſhall ſuffer a year's impriſonment. Thus much for perſons, who, from the misfortune of family prejudices, or otherwiſe, have conceived an unhappy attachment to the Romiſh church from their infancy, and publicly profeſs its errors. But if any evil induſtry is uſed to rivet theſe errors upon them; if any perſon ſends another abroad to be educated in the Popiſh relig[illegible] to reſide in any religious houſe abroad for that pu[illegible], or contributes to their maintenance when there; both the ſender, the ſent, and the contributor, are diſabled to ſue in law or equity, to be executor or adminiſtrator to any perſon, to take any legacy or deed of gift, and to bear any office in the realm; and ſhall forfeit all their goods and chattels, and likewiſe all their real eſtate for life. And where theſe errors are alſo aggravated by apoſtacy or perverſion; where a perſon is reconciled to the ſee of Rome, or procures others to be reconciled, the offence amounts to high treaſon. 2. Popiſh recuſants, convicted in a court of law of not attending the ſervice of the church of England, are ſubject to the following diſabilities, penalties, and forfeitures, over and above thoſe before mentioned. They are conſidered as perſons excommunicated; they can hold no office or employment: they muſt not keep arms in their houſes, but the ſame may be ſeized by the juſtices of the peace; they may not come within 10 miles of London, on pain of 100l.; they can bring no action at law or ſuit in equity; they are not permitted to travel above five miles from home, unleſs by licenſe, upon pain of forfeiting all their goods; and they may not come to court, under pain of 100l. No marriage or burial of ſuch recuſant, or baptiſm of his child, ſhall be had otherwiſe than by the miniſters of the church of England, under other ſevere penalties. A married woman, when recuſant, ſhall forfeit two thirds of her dower or jointure, may not be executrix or adminiſtratrix to her huſband, nor have any part of his goods; and during the coverture may be kept in priſon, unleſs her huſband redeems her, at the rate of 10l. a month, or the third part of all his lands. And laſtly, as a feme-couvert recuſant may be impriſoned, ſo all others muſt, within three months after conviction, either ſubmit and renounce their errors, or, if required ſo to do by four juſtices, muſt abjure and renounce the realm: and if they do not depart, or if they return without the king's licenſe, they ſhall be guilty of felony, and ſuffer death as felons without benefit of clergy. There is alſo an inferior ſpecies of recuſancy, (refuſing to make the declaration againſt Popery enjoined by ſtatute 30 Car. II. ſt. 2. when tendered by the proper magiſtrate); which, if the party reſides within ten miles of London, makes him an abſolute recuſant convict; or, if at a greater diſtance, ſuſpends him from having any ſeat in parliament, keeping arms in his houſe, or any horſe above the value of 5l. 3. Popiſh prieſts are in a ſtill more dangerous condition. By ſtatute 11 & 12 W. III. c. 4. Popiſh prieſts, or biſhops, celebrating maſs or exerciſing any part of their functions in England, except in the houſes of ambaſſadors, are liable to perpetual impriſonment. And by the ſtatute 27 Eliz. c. 2. any Popiſh prieſt, born in the dominions of the crown of England, who ſhall come over hither from beyond ſea (unleſs driven by ſtreſs of weather and tarrying only a reaſonable time), or ſhall be in England three days without conforming and taking the oaths, is guilty of high treaſon: and all perſons harbouring him are guilty of felony without the benefit of clergy.

Nonconformiſts.

This is a ſhort ſummary of the laws againſt the Papiſts; of which the preſident Monteſquieu obſerves, that they are ſo rigorous, though not profeſſedly of the ſanguinary kind, that they do all the hurt that can poſſibly be done in cold blood. But in anſwer to this, it may be obſerved (what foreigners who only judge from our ſtatute book are not fully appriſed of), that theſe laws are ſeldom exerted to their utmoſt rigour: and indeed, if they were, it would be very difficult to excuſe them. For they are rather to be accounted for from their hiſtory, and the urgency of the times which produced them, than to be approved (upon a cool review) as a ſtanding ſyſtem of law. The reſtleſs machinations of the Jeſuits during the reign of Elizabeth, the turbulence and uneaſineſs of the Papiſts under the new religious eſtabliſhment, and the boldneſs of their hopes and wiſhes for the ſucceſſion of the queen of Scots, obliged the parliament to counteract ſo dangerous a ſpirit by laws of a great, and then perhaps neceſſary, ſeverity. The powder-treaſon, in the ſucceeding reign, ſtruck a panic into James I. which operated in different ways: it occaſioned the enacting of new laws againſt the Papiſts; but deterred him from putting them in execution. The intrigues of Queen Henrietta in the reign of Charles I. the proſpect of a Popiſh ſucceſſor in that of Charles II. the aſſaſſination-plot in the reign of King William, and the avowed claim of a Popiſh pretender to the crown in ſubſequent reigns, will account for the extenſion of theſe penalties at thoſe ſeveral periods of our hiſtory." But now that all juſt fears of a pretender may be ſaid to have vaniſhed, and the power and influence of the pope has become feeble, ridiculous, and deſpicable, not only in Britain, but in almoſt every kingdom of Europe: and as in fact the Britiſh Catholics ſolemnly diſclaim the dangerous principles aſcribed to them *; the Britiſh legiſlature, giving way to that liberality of ſentiment becoming Proteſtants, have lately repealed the moſt rigorous of the above edicts, *viz.* The puniſhment of Popiſh prieſts or Jeſuits who ſhould be found to teach or officiate in the ſervices of that church; which acts were felony in foreigners, and high treaſon in the natives of this kingdom:—The forfeitures of Popiſh heirs, who had received their education abroad; and whoſe eſtates went to the next Proteſtant heir:—The power given to the ſon, or other relation, being a Proteſtant, to take poſſeſſion of the father's or other relation's eſtate, during the life of the real proprietor:—And the debarring Papiſts from the power of acquiring any legal property by purchaſe.—In propoſing the repeal of theſe penalties, it was obſerved, That, beſides that ſome of them had now ceaſed to be neceſſary, others were at all times a diſgrace to humanity. The impriſonment of a Popiſh prieſt for life, only officiating in the ſervices of his religion, was horrible in its nature: And although the mildneſs of government had hitherto ſoftened the rigour of the law in the practice, it was to be remembered that the Roman Catholic prieſts conſtantly lay at the mercy of the baſeſt and moſt abandoned of mankind—of common informers; for on the evidence of any of theſe wretches, the magiſterial and judicial powers were of neceſſity bound to enforce all the ſhameful penalties of the act. Others of theſe penalties held out the moſt powerful temptations for the commiſſion of acts of depravity, at the very thought of which our nature recoils with horror: They ſeemed calculated to looſen all the bands of ſociety; to diſſolve all civil, moral, and religious obligations and duties, to poiſon the ſources of domeſtic felicity, and to annihilate every principle of honour. The encouragement given to children to lay their hands upon the eſtates of their parents, and the reſtriction which debars any man from the honeſt acquiſition of property, need only to be mentioned to excite indignation in an enlightened age.

---

* See their loyal Addreſs to the Throne, May 1 1778, as inſerted in the Magazines or Annual Regiſter for that year.

In order the better to ſecure the Engliſh eſtabliſhed church againſt perils from nonconformiſts of all denominations, Infidels, Turks, Jews, Heretics, Papiſts, and Sectaries, there are, however, two bulwarks erected; called the *corporation* and *teſt acts*: By the former of which, no perſon can be legally elected to any office relating to the government of any city or corporation, unleſs, within a twelvemonth before, he has received the ſacrament of the Lord's ſupper according to the rites of the church of England; and he is alſo enjoined to take the oaths of allegiance and ſupremacy at the ſame time that he takes the oath of office: or, in default of either of theſe requiſites, ſuch election ſhall be void. The other, called the *teſt act*, directs all officers civil and military to take the oaths and make the declaration againſt tranſubſtantiation, in any of the king's courts at Weſtminſter, or at the quarter ſeſſions, within ſix kalendar months after their admiſſion; and alſo within the ſame time to receive the ſacrament of the Lord's ſupper, according to the uſage of the church of England, in ſome public church immediately after divine ſervice and ſermon, and to deliver into court a certificate thereof ſigned by the miniſter and church warden, and alſo to prove the ſame by two credible witneſſes; upon forfeiture of 500l. and diſability to hold the ſaid office. And of much the ſame nature with theſe is the ſtatute 7 Jac. I. c. 2. which permits no perſons to be naturalized or reſtored in blood, but ſuch as undergo a like teſt: which teſt having been removed in 1753, in favour of the Jews, was the next ſeſſion of parliament reſtored again with ſome precipitation.

Non-Naturals, in medicine, ſo called, becauſe by their abuſe they become the cauſes of diſeaſes.

Phyſicians have divided the non-naturals into ſix claſſes, viz. the air, meats and drinks, ſleep and watching, motion and reſt, the paſſions of the mind, the retentions and excretions. See Medicine, *paſſim*.

Non Obſtante, *(notwithſtanding)* a clauſe frequent in ſtatutes and letters patent, importing a licenſe from the king to do a thing, which at common law might be lawfully done, but being reſtrained by act of parliament cannot be done without ſuch licenſe.

Non Proſ. See Nolle *Proſequi*.

Non-Suit, ſignifies the dropping of a ſuit or action, or a renouncing thereof by the plaintiff or defendant; which happens moſt commonly upon the diſcovery of ſome error in the plaintiff's proceedings when the cauſe is ſo far proceeded in, that the jury is ready at the bar to deliver in their verdict.

NONES, (nonæ), in the Roman kalendar, the fifth day of the months January, February, April, June, Auguſt, September, November, and December; and the ſeventh of March, May, July, and October. March, May, July, and October, had ſix days in their nones; becauſe theſe alone, in the ancient conſtitution of the year by Numa, [illegible] 31 days a-piece, the reſt having only 29, and F[illegible] 30: but when Cæſar reformed the year, and m[illegible]ther months contain 31 days, he did not allot them ſix days of nones.

NONJURORS, thoſe who refuſed to take the oaths to government, and who were in conſequence under certain incapacities, and liable to certain ſevere penalties. It can ſcarcely be ſaid that there are any nonjurors now in the kingdom; and it is well known that all penalties have been removed both from Papiſts and Proteſtants, formerly of that denomination, as well in Scotland as in England. The members of the Epiſcopal church of Scotland have long been denominated Nonjurors; but perhaps they are now called ſo improperly, as the ground of their difference from the eſtabliſhment is more on account of eccleſiaſtical than political principles.

NONIUS (Peter), in Spaniſh *Nunez*, a learned Portugueſe, and one of the ableſt mathematicians of the 16th century, was born at Alcacer. He was preceptor to Don Henry, King Emmanuel's ſon, and taught the mathematics in the univerſity of Coimbra. He publiſhed the following works, by which he gained great reputation: 1. *De arte navigandi*. 2. *Annotationes in theorias planetarum Purbachii*; which are greatly eſteemed. 3. A treatiſe *De Crepuſculis*. 4. A treatiſe on algebra. It is obſerved in Furetiere's dictionary, that Peter Nonius, in 1530, firſt invented the angles of 45 degrees made in every meridian, and that he called them *rhumbs* in his language, and calculated them by ſpherical triangles. Nonius died in 1577, aged 80.

Nonius, the name which was not many years ago given to the common device for ſubdividing the arcs of quadrants and other aſtronomical inſtruments, from the perſuaſion that it was invented by *Nonius* or *Nunez*, of whom ſome account has been given in the preceding article. The generality of aſtronomers of the preſent age transferring the honour of the invention from *Nunez* to *Peter Vernier*, a native of Franche Comte, have called this method of diviſion by his name. (See Vernier). Mr Adams, however, in his *Geometrical and Geographical Eſſays*, has lately ſhown that Clevius the Jeſuit may diſpute the invention with them both. The truth ſeems to be, that Nunez ſtarted the idea, Clevius improved it, and Vernier carried it to its preſent ſtate of perfection. The method of Nunez, deſcribed in his treatiſe *De Crepuſculis*, printed at Liſbon 1542, conſiſts in deſcribing within the ſame quadrant 45 concentric circles, dividing the outermoſt into 90 equal parts, the next within into 89, the next into 88, &c. till the innermoſt was divided into 46 only. On a quadrant thus divided the plumb line or index muſt croſs one or other of the circles very near a point of diviſion; whence, by computation, the degrees and minutes of the arch might be eaſily aſcertained. This method is alſo deſcribed by Nunez in his treatiſe *De arte atque ratione navigandi*, where he would fain perſuade himſelf, that it was not unknown to Ptolemy. But as the degrees are thus divided very unequally, and as it is very difficult to attain exactneſs in the diviſion, eſpecially when the numbers into which the arches are to be divided are incompoſite (of which there are no leſs than nine), the method of diagonals, firſt publiſhed by Thomas Digges Eſq; in a treatiſe entitled *Al*[illegible]*ale mathematicæ*, printed at London in 1573, an[illegible] to be invented by one Richard Chenſeler, was ſubſtituted in its room. Nonius's method was, however, improved at different times and by different perſons; and it muſt be acknowledged, that if Vernier ſaw either the original or any of the improvements (and there can be little doubt of his having ſeen them all), his merit is only that of having applied to an uſeful practical purpoſe the ſpeculative invention of another perſon.

NONIUS (Marcellus), a grammarian, and Peripatetic philoſopher, born at Tivoli, wrote a treatiſe, entitled *De proprietate ſermonum*. This author is only valuable for his giving fragments of ancient authors that are nowhere elſe to be found. The above treatiſe was printed at Paris in 1614, with notes.

NONNIUS, or NONIUS (Lewis,) a learned phyſician of Antwerp in the 17th century, wrote ſeveral works which are eſteemed; the principal of which are, 1. An excellent treatiſe entitled *Ichthyophagia, ſive de Piſcium eſu*. 2. *Hiſpania*; which is of great uſe in underſtanding the ancient geography of Spain. 3. A commentary on the medals of Greece, and thoſe of Julius Cæſar, Auguſtus, and Tiberius, in folio; it contains Goltzius's two works on the ſame ſubject. 4. A commentary on Goltzius's account of Greece, the Iſlands, &c. 5. Poems, &c.

NONNUS, a Greek poet of the 5th century, and native of Panopilis in Egypt, was the author of an heroic poem in 48 books, entitled *Dionyſiacorum*, and a paraphraſe in verſe of St John's Goſpel, which may ſerve as a commentary upon it.

NONUPLA, in the Italian muſic, denotes a quick time, peculiar to jigs. This ſpecies of time is otherwiſe called *the meaſure of nine times*, which requires two falls of the hand, and one riſe. There are three ſorts of nonupla. 1. *Nonupla di ſemi minime*, or *dupla ſeſquiquarta*, thus marked $\frac{9}{4}$, where nine crotchets are to be in the bar, of which four make a ſemibreve in common time, *i. e.* in the down ſtroke ſix, and but three up: it is uſually beat *adagio*. 2. *Nonupla di crome*, or *ſeſqui ottava*, marked thus $\frac{9}{8}$, wherein nine quavers make a bar inſtead of eight in common time, *i. e.* ſix down and three up: it is beat *preſto*. 3. *Nonupla di ſemi-crome* or *ſuper ſetti partiente nona*, thus diſtinguiſhed $\frac{9}{16}$, in which nine ſemiquavers are contained in a bar, whereof ſixteen are required in common time, ſix down, and three up: it is ordinarily beat *preſtiſſimo*. Beſide theſe, there are two other ſpecies of nonupla, for which ſee TRIPLE.

NOOTKA SOUND, or, as it was called by Captain Cook, *King George's Sound*, lies Lat. 49. 33. W. Long. 153. 12. It is an entrance or ſtrait to a vaſt inland ſea on the weſt coaſt of North America, and is ſaid to reſemble the Baltic or Mediterranean in Europe. Upon the ſea-coaſt the land is tolerably high and level; but within the ſound it riſes into ſteep hills, which have an uniform appearance. The trees of which the woods are compoſed, are the Canadian pine, white cypreſs, and two or three other ſorts of pine. In general, the trees grow here with great vigour, and are of a large ſize. About the rocks and borders of the woods were ſeen ſome ſtrawberry plants, and raſpberry, currant, and gooſeberry buſhes, all in a flouriſhing ſtate. The principal animals ſeen here were racoons, martens, and ſquirrels. Birds are far from being numerous, and thoſe that are to be ſeen are remarkably ſhy, owing perhaps to their being continually haraſſed by the natives, either to eat them, or to become poſſeſſed of their feathers to be worn as ornaments. The quebrantahueſſos, ſhags, and gulls, were ſeen off the coaſt; and the two laſt were alſo frequent in the ſound. Though the variety of fiſh is not very great, yet they are in greater quantities than [illegible]. The principal ſorts are the common herring, a ſilver coloured bream, and another of a brown colour. Captain Cook and Mr King, who viſited this place, conſider it as an excellent ſhelter for ſhips: and in the account of *A Voyage to the Pacific Ocean*, they give ſome directions for ſailing into it. Theſe and other matters of that kind we ſhall not trouble our readers with; and perhaps the generality of them will be better pleaſed with the following extract from Meares's Voyages to the North-weſt Coaſt of America.

"The people of the Nootka nation are, in general, robuſt and well proportioned:—their faces are large and full, their cheeks high and prominent, with ſmall black eyes:—their noſes are broad and flat, their lips thick, and they have generally very fine teeth, and of the moſt brilliant whiteneſs.

"The manner in which the children of Nootka are treated, when young, is not more extraordinary from its ſtrange, and, as it ſhould appear, total inutility, as from its agreement with the cuſtoms of the Chineſe and Tartars, to whom this practice gives theſe people a conſiderable reſemblance. The head of the infant is bound by the mother with a kind of fillet of ſeveral folds, as low down as the eyes, in order to give it a certain form, which, at this tender age, it is capable of receiving. It might be ſuppoſed, that ſuch a tight drawn ligature muſt cauſe conſiderable pain to the child; but we never obſerved that any of the infants, in ſuch a ſtate of preparation for ſugar-loaf heads, ſuffered any viſible pain or inconvenience.

"Though the cuſtom of compreſſing the head in this manner gives them an unpleaſant appearance, by drawing up the eyebrows, and ſometimes producing the diſagreeable effect of ſquinting, as well as of flattening the noſe and diſtending the noſtrils, they are by no means an ill-looking race of people. They have alſo the cuſtom, which is known to prevail in ſo many Indian nations, of plucking out the beard by the roots, on its firſt appearance; and, as it continues to ſprout, to keep it down by the ſame practice. It is one of the domeſtic employments aſſigned to their wives, to watch this appearance of manhood, and to eradicate the hairs as they come forth; which they do in a very dexterous manner with their fingers, and without giving the leaſt pain in the operation.—Some of them, however, though we ſaw but very few of this diſpoſition, when they advance in years and become infirm, ſuffer their beards to grow without interruption. But, notwithſtanding

Nootka Sound.

ſtanding they have ſo great an averſion to the hair of their chin, that of the head is an object of their attentive vanity: it is ſtrong, black, and gloſſy; grows to a conſiderable length; and is either tied in a kind of knot on the top of their heads, or ſuffered to hang down their backs in flowing negligence.

"In their exterior form they have not the ſymmetry or elegance which is found in many other Indian nations.—Their limbs, though ſtout and athletic, are crooked and ill ſhaped; their ſkin, when cleanſed of filth and ochre, is white; and we have ſeen ſome of the women, when in a ſtate of cleanlineſs (which, however, was by no means a common ſight, and obtained with difficulty), who not only poſſeſſed the fair complexion of Europe, but features that would have attracted notice, for their delicacy and beauty, in thoſe parts of the world where the qualities of the human form are beſt underſtood. But theſe examples of beauty are by no means numerous among the women of Nootka, who are calculated rather to diſguſt than to charm an European beholder. Their hair, like that of the men, is black; their eyes are of the ſame colour; and, in exterior appearance, they are not to be immediately diſtinguiſhed from the men. In their characters they are reſerved and chaſte; and examples of looſe and immodeſt conduct were very rare among them. There were women in St George's Sound, whom no offers could tempt to meretricious ſubmiſſions."

All reports concerning Nootka Sound agree in characterizing the inhabitants as "a very inoffenſive race of people."—Inoffenſive, however, as they are, a cuſtom of a very unnatural, and we ſhould imagine cruel, kind prevails among them: for, together with many other articles which they expoſed to ſale to Captain Cook's ſhips, they brought human ſkulls and hands (part of the fleſh ſtill remaining on them), which they acknowledged they had been feeding on; and ſome of them, we are told, had evident marks of the fire.

From hence it is too apparent, that the horrid practice of devouring their enemies exiſts here as well as at New Zealand and other South ſea iſlands: and hence, too, appears what men of even the beſt natural diſpoſitions will be, if left entirely to the freedom of their own will, without law to controul or religion to inſtruct them. As there are but two villages of the Sound inhabited, the number of people cannot be many; perhaps they are about 2000 in all. Our limits prevent us from being ſo minute as we could wiſh to be, reſpecting the form of their houſes and their manner of building them; of their furniture, decorations, and other things of that kind: we can therefore only refer thoſe who wiſh for further information on this ſubject to Cook, and other voyagers and travellers, &c.

The employment of the men is chiefly fiſhing, &c. whilſt the women manufacture their garments. Their ingenuity in this and in the mechanic arts is far from being inconſiderable; and in the imitative arts their ſkill is very great. On theſe ſubjects, however, we cannot enlarge: we have in general made it our buſineſs, and it certainly is our duty, to dwell, where it can be done, on the manners or religion of the inhabitants of the ſeveral places which come under our notice; and they who know the utility of this in developing the philoſophy of the human mind, the moſt important of all ſciences, will not blame our intentions, even if they ſhould not approve of the execution. In Cook's Voyages before referred to, we find the following obſervations on the religion and language of the inhabitants of Nootka Sound.

"Little knowledge we can be ſuppoſed to have acquired of the political and religious inſtitutions eſtabliſhed among theſe people. We diſcovered, however, that there were ſuch men as chiefs, diſtinguiſhed by the title of *Acw*[illegible] whom the others are, in ſome degree, ſubord[illegible] But the authority of each of theſe great me[illegible]ms to extend no farther than to his own family, who acknowledge him as their head. As they were not all elderly men, it is poſſible this title may be hereditary.

"Nothing that we ſaw could give us any inſight into their notions of religion, except the figures already mentioned, called *Klumma*. Theſe, perhaps, were idols; but as the word *acweek* was frequently mentioned when they ſpoke of them, we may ſuppoſe them to be the images of ſome of their anceſtors, whoſe memories they venerate. This, however, is all conjecture; for we could receive no information concerning them; knowing little more of their language than to enable us to aſk the names of things, and being incapable of holding any converſation with the natives relative to their traditions or their inſtitutions.

"Their language is neither harſh nor diſagreeable, farther than proceeds from their pronouncing the *k* and *h* with leſs ſoftneſs than we do. As to the compoſition of their language, we are enabled to ſay but little. It may, however, be inferred from their ſlow and diſtinct method of ſpeaking, that it has few prepoſitions or conjunctions, and is deſtitute of even a ſingle interjection to expreſs ſurpriſe or admiration. The affinity it may bear to other languages, we have not been able ſufficiently to trace, not having proper ſpecimens to compare it with; but from the few Mexican words we have procured, there is an obvious agreement throughout the language, in the fre[illegible] terminations of the words in *l*, *tl*, or *z*.

"The word *wakaſh* was frequently in the mouths of the people of Nootka. It ſeemed to expreſs approbation, applauſe, and friendſhip. Whenever they appeared to be pleaſed or ſatisfied at any ſight or occurrence, they would call out *wakaſh! wakaſh!*—It is worthy of remark, that as theſe people do eſſentially differ from the natives of the iſlands in the Pacific ocean, in their perſons, cuſtoms, and language, we cannot ſuppoſe their reſpective progenitors to have belonged to the ſame tribe, when they emigrated into thoſe places where we now find their deſcendants."

We cannot finiſh this article without taking notice of a circumſtance, which at the time made a great noiſe in Europe, and which it is probable will find a place in the future hiſtories of the contending countries.

A ſmall aſſociation of Britiſh merchants reſident in the Eaſt Indies had, early in the year 1786, formed the project of opening a trade to this part of the world, for the purpoſe of ſupplying the Chineſe market with furs. The principal point towards which theſe expeditions were directed, was Port Nootka, or King George's Sound; and the adventurers, being in ſome degree ſatisfied with their traffic, took meaſures, in the year 1788, to ſecure to themſelves a permanent ſettlement; at the ſame time that the ſhipping employed in this expedition was generally two, and never exceeded the amount of four, ſmall veſſels. The Spaniards conceived ſome jealouſy of the intruſion of the Engliſh into a part of the world which they had long been deſirous to regard as their excluſive property; and accordingly a Spaniſh frigate of 26 guns was deſpatched from the province of Mexico, for the purpoſe of putting an end to this comm[illegible]. The Spaniſh frigate arrived in May 1789, and [illegible]red two Engliſh veſſels in the following July, [illegible] ſame time taking poſſeſſion of the little ſettlement which had been formed upon the coaſt. Such, in ſhort, is the circumſtance which was likely to involve us in an expenſive war. Happily, however, for both countries, and perhaps for Europe, the matter was at length, after great altercation, amicably ſettled; and it muſt ſtill be ſo freſh in the memories of our readers, that we truſt they will excuſe us from enlarging further upon it—the whole article having extended perhaps to more than a ſufficient length.

NOPAL, RAQUETTE, or *Indian fig*; plants ſo named by the Indians from which the cochineal is collected in Mexico. Theſe plants bear fruits which reſemble our figs; tinge the urine of thoſe who eat them; and probably communicate to the cochineal the property which makes it uſeful to the dyer. The Indians of Mexico cultivate the nopal near their habitations, and ſow, as it were, the inſect which affords the cochineal. They make ſmall neſts of moſs or fine herbs; put twelve or fourteen cochineals into each neſt; place three or four of theſe neſts on each leaf of the nopal; and faſten them there by the prickles of the plant. In the courſe of a few days, thouſands of ſmall inſects iſſue out, and fix themſelves upon the parts of the leaf which are beſt ſheltered and afford the moſt nouriſhment. The cochineals are collected ſeveral times in the courſe of the year; and are deprived of life by ſcalding them, or by putting them into an oven. See COCHINEAL.

Plate CCCXLVI NOPALXOCHQUETZALLI, or NOPALCOCHQUETZALLI, the prickly pear of Mexico, and common over all the Weſt Indies. See CACTUS.

NOPH. See MEMPHIS.

NORBURY, a town in England, in Staffordſhire, on the ſouth-weſt ſide of Eccleſhall. Here is a ſurpriſing echo, which, taken 440 yards north-eaſt from the manor houſe, near a little bank under a wood ſide, repeats in a ſtill day 10 or 11 ſyllables very diſtinctly, or 12 or 13, if ſpoke very quick. It is remarked that the banks of the Black Meer, in this pariſh, grow forward every year over the ſurface of the water, at the rate of three or four yards every ſeven years.

NORDEN (Frederic Lewis), an ingenious traveller and naval officer in the Daniſh ſervice, was born at Gluckſtadt in Holſtein in the year 1708. He was well ſkilled in mathematics, ſhip building, and eſpecially in architecture; and in 1732 obtained a penſion to enable him to travel for the purpoſe of ſtudying the conſtruction of ſhips, particularly the galleys and other rowing veſſels uſed in the Mediterranean. He ſpent near three years in Italy; and Chriſtian VI. being deſirous of obtaining a circumſtantial account of Egypt, Mr Norden at Florence received an order to extend his travels to that country. How he acquitted himſelf in this commiſſion, appears from his Travels into Egypt and Nubia, printed at Copenhagen in folio, 1756; and which were ſoon after tranſlated into Engliſh by Dr Peter Templeman. In the war between England and Spain, Mr Norden, then a captain in the Daniſh navy, attended Count Ulric Adolphus, a ſea captain, to England; and they went out volunteers under Sir John Norris, and afterwards under Sir Chaloner Ogle. During his ſtay in London, Mr Norden was made a fellow of the Royal Society, and gave the public drawings of ſome ruins and coloſſal ſtatues at Thebes in Egypt, with an account of the ſame in a letter to the Royal Society, 1741. His health at this time was declining; and taking a tour to France, he died at Paris in 1742.

NORDHEIM, a town in Germany, in the Hanover quarter. Of the four larger towns of this principality, it is the third in order. It is ſituated on the Ruhme, which runs into the Leine. It contains 500 houſes, and, beſides a ſecularized Lutheran abbey, has one pariſh church, and ſome charitable foundations, and alſo enjoys ſome manufactures.

NORES (Jaſon de), a ſcholar, poet, and philoſopher, was born at Nicoſia in Cyprus. He loſt his fortune when the Turks made themſelves maſters of that iſland in 1570. He retired to Padua; where he acquired great reputation by teaching moral philoſophy. His character had that caſt of ſeverity which is often the conſequence of ſcholaſtic habits. He was one of thoſe men who diſcuſs every thing without being capable of feeling any thing. The *Paſtor Fido* of Gaurini made its appearance; and paſtorals became a faſhionable ſpecies of reading throughout all Itally. Nores, who did not reliſh works of this kind, attacked the production of Guarini; who entirely confuted him in a little piece printed at Ferrara in 1588. Nores made a reply two years after; and the poet was preparing an anſwer ſtill more ſevere than the former, when his antagoniſt died of grief occaſioned by the baniſhment of his only ſon for having killed a Venetian in a duel. He left behind him a great many works, ſome in Italian, and others in Latin. The chief of his Italian works, are, 1. The Poeticks, Padua, 1588, 4to; this edition is rare. 2. A Treatiſe on Republics, 1578, 4to; which he forms on the model of that of the Venetians, his maſters. 3. A Treatiſe on the World and its Parts, Venice, 1571, 8vo. 4. Introduction to three books of Ariſtotle's Rhetoric, Venice, 1584, 4to, valuable. 5. A Treatiſe on what Comedy, Tragedy, and Epic Poetry, may receive from Moral Philoſophy. His Latin works are, 1. *Inſtitutio in Philoſophiam Ciceronis*, Padua, 1576, 8vo. 2. *Brevis et diſtincta ſumma præceptorum de arte diſcendi, ex libris Ciceronis collecta*, Venice, 1553, 8vo; a good work. 3. *De Conſtitutione partium humanæ et civilis philoſophiæ*, 4to. 4. *Interpretatio in artem poeticam Horatii*, &c. In all his works we remark great perſpicuity and accuracy, profound erudition, happy expreſſions, an elevated and ſometimes forcible ſtyle.—His ſon Peter Nores, ſucceſſively ſecretary to ſeveral cardinals, at once a man of letters and a man of buſineſs, left behind him different manuſcripts; among others, the life of Paul IV. in Italian.

NORFOLK, a county of England, ſo called from

Norfolk.

its northen ſituation in reſpect of Suffolk, is bounded on the eaſt and north by the German ocean; on the ſouth by Suffolk, from which it is parted by the rivers Waveney, and the Leſſer Ouſe; and on the weſt it is ſeparated from Cambridgeſhire by the Greater Ouſe, and from a ſmall part of Lincolnſhire by the Waſhes. According to Templeman, it extends in length 57 miles, in breadth 35, and 140 in circumference. It contains an area of 1426 ſquare miles, one city, 32 market towns, 711 villages, according to the book of rates, though ſome make them 1500, and 236,000 inhabitants, as ſome have it, and 283,000, according to others. It is divided into 31 hundreds, 164 vicarages, and 660 pariſhes.

The air differs in different parts of the county according to the ſoil, which in ſome places is marſhy, eſpecially on the ſea coaſt, and there the air is foggy and unwholeſome; in others it is clayey and chalky, poor, lean, and ſandy, and there the air is good. The county is almoſt all champaign, except in ſome places, where riſe gentle hills. The marſh lands yield rich paſture for cattle; the clay grounds peaſe, rye, and barley; and the ſandy heaths feed vaſt flocks of large ſheep, of which ſome villages are ſaid to keep 4000 or 5000. Theſe heaths abound alſo in rabbits of a ſilver gray colour. Walſingham is noted for producing the beſt ſaffron. Great quantities of mackarel and herring are caught upon the coaſts of this county, the former in the ſpring, and the latter in September; eſpecially at Yarmouth, where they are cured in a particular manner, and to great perfection. Wood and honey are alſo very plentiful in this county; and on the coaſts jet and ambergreaſe are ſometimes found. The inhabitants are generally ſtrong and active, ſagacious and acute. That they are ſo robuſt, is the more to be wondered at, becauſe the common people live much on puddings, *Norfolk dumplings*. They are for the moſt part in eaſy circumſtances, and were formerly very quarrelſome and litigious. In conſequence of this diſpoſition, lawyers ſwarmed among them to ſuch a degree, that a ſtatute was made ſo early as the reign of Henry VI. to reſtrain their number. The manufactures of the county, which is exceedingly populous, are chiefly woollen and worſted ſtuffs and ſtockings, for which they are well ſupplied with wool from the vaſt flocks of ſheep bred in it. It gives title of duke to the elder branch of the family of Howard, lies in the dioceſe of Norwich, and ſends twelve members to parliament, viz. two knights for the ſhire, two citizens for Norwich, and two burgeſſes for each of the boroughs of Lynn Regis, Great Yarmouth, Thetford, and Caſtleriſing.

The county is well watered, and ſupplied with fiſh by the rivers Yare, Thyrn, Waveney, the Greater and Leſſer Ouſe, and the Bure, beſides rivulets. The Bure abounds in excellent perch, and the Yare has a fiſh peculiar to it called the *ruffe*. The latter riſes about the middle of the county; and after being joined by the Waveney and Bure, falls into the ſea at Yarmouth. At the equinoxes, eſpecially the autumnal, the Ouſe is ſubject to great inundation, being forced back by the ſea, that enters it with great fury. This county was famous at a very early period for its fiſheries, which were extenſive and valuable, and ſeem to have been carried on with ſpirit. It has alſo been remarkable, for at leaſt 400 years paſt, for the manufacture of fine worſted ſtuffs.

Norfolk, Norfolk Iſland

Norfolk, a county of Virginia contiguous to North Carolina.

Norfolk Iſland, a pretty little iſland of the South ſea, lying in 29° 12′ 30″ ſouth latitude, and 168° 16′ eaſt longitude. A colony was lately ſettled on it: and the following account of it is given in *Governor Phillip's Voyage to Botany Bay*, &c.

"Norfolk Iſland is about ſeven leagues in circumference; and [illegible] originally formed, like many other ſmall iſlands, [illegible] eruption of volcanic matter from the bed of the ſea, muſt doubtleſs have contained a volcano. This concluſion is formed from the vaſt quantity of pumice ſtone which is ſcattered in all parts of it, and mixed with the ſoil. The crater, or at leaſt ſome traces of its former exiſtence, will probably be found at the ſummit of a ſmall mountain, which riſes near the middle of the iſland. To this mountain the commandant has given the name of *Mount Pitt*. The iſland is exceedingly well watered. At or near Mount Pitt riſes a ſtrong and copious ſtream, which flowing through a very fine valley, divides itſelf into ſeveral branches, each of which retains ſufficient force to be uſed in turning mills; and in various parts of the iſland ſprings have been diſcovered.

"The climate is pure, ſalubrious, and delightful, preſerved from oppreſſive heats by conſtant breezes from the ſea, and of ſo mild a temperature throughout the winter, that vegetation continues there without interruption, one crop ſucceeding another. Refreſhing ſhowers from time to time maintain perpetual verdure: not indeed of graſs, for none has yet been ſeen upon the iſland: but of the trees, ſhrubs, and other vegetables, which in all parts grow abundantly. On the leaves of theſe, and of ſome kinds in particular, the ſheep, hogs, and goats, not only live, but thrive and fatten very much. To the ſalubrity of the air every individual in this little colony can bear ample teſtimony, from the uninterrupted ſtate of good health which has been in general enjoyed.

"When our ſettlers landed, there was not a ſingle acre clear of wood in the iſland, and the trees were ſo bound together by that kind of creeping ſhrub called *ſupple jack*, interwoven in all directions, as to render it very difficult to penetrate far among them. The commandant, ſmall as his numbers were at firſt, by indefatigable activity ſoon cauſed a ſpace to be cleared ſufficient for the requiſite accommodations, and for the production of eſculent vegetables of all kinds in the greateſt abundance. When the laſt accounts arrived, three acres of barley were in a very thriving ſtate, and ground was prepared to receive rice and Indian corn. In the wheat there had been a diſappointment, the grain that was ſown having been ſo much injured by the weevil as to be unfit for vegetation. But the people were all at that time in commodious houſes; and, according to the declarations of M. King himſelf, in his letters to Governor Phillip, there was not a doubt that this colony would be in a ſituation to ſupport itſelf entirely without aſſiſtance in leſs than four years; and with very little in the intermediate time. Even two years would be more than ſufficient for this purpoſe, could a proper ſupply of black cattle be ſent.

"Fiſh are caught in great plenty, and in the proper ſeaſon very fine turtle. The woods are inhabited by innumerable tribes of birds, many of them very gay in plumage. The moſt uſeful are pigeons, which are very numerous; and a bird not unlike the Guinea fowl, except in colour (being chiefly white), both of which were at firſt ſo tame as to ſuffer themſelves to be taken by hand. Of plants that afford vegetables for the table, the chief are cabbage palm, the wild plantain, the fern tree, a kind of [illegible] ſpinage, and a tree which produces a diminutive [illegible] bearing ſome reſemblance to a currant. This, it is hoped, by tranſplanting and care, will be much improved in ſize and flavour.

"But the productions which give the greateſt importance to Norfolk Iſland are the pines and the flax plant; the former riſing to a ſize and perfection unknown in other places, and promiſing the moſt valuable ſupply of maſts and ſpars for our navy in the Eaſt Indies; the latter not leſs eſtimable for the purpoſes of making ſail cloth, cordage, and even the fineſt manufactures, growing in great plenty, and with ſuch luxuriance as to attain the height of eight feet. The pines meaſure frequently 160, or even 180 feet in height, and are ſometimes 9 or 10 feet in diameter at the bottom of the trunk. They riſe to about 80 feet without a branch: the wood is ſaid to be of the beſt quality, almoſt as light as that of the beſt Norway maſts; and the turpentine obtained from it is remarkable for purity and whiteneſs. The fern tree is found alſo of a great height for its ſpecies, meaſuring from 70 to 80 feet, and affords excellent food for the ſheep and other ſmall cattle. A plant producing pepper, and ſuppoſed to be the true oriental pepper, has been diſcovered lately in the iſland, growing in great plenty; and ſpecimens have been ſent to England in order to aſcertain this important point."

NORFOLK Sound, according to the account of Captain George Dixon, is ſituated in 57° 3′ north latitude, and 135° 36′ weſt longitude. It is a very extenſive place, but how far it ſtretches to the northward is not known. There may poſſibly be a paſſage through to the Bay of Iſlands, but neither is this certain. The ſhore, in common with the reſt of the coaſt, abounds with pines; there are alſo great quantities of the witch hazel. There are various kinds of flowering trees and ſhrubs, wild gooſberries, currants, and raſpberries; wild parſley is found here in great plenty, and it eats excellently either as a ſalad or boiled amongſt ſoup. The ſaranne, or wild lily root, grows alſo in great plenty and perfection. There are a very few wild geeſe or ducks ſeen here, but they are ſhy and difficult of approach.

NORHAM, a town in England, in the county of Northumberland, on the river Tweed, near the mouth of the Till, under the caſtle, which was anciently erected on a ſteep rock moated round, for the better ſecurity againſt the incurſions of the Scotch moſs troopers. It is of great antiquity; and its old church has lately received repairs, and been made a decent place of worſhip. Antiquities have been diſcovered here. The church had the privilege of a ſanctuary. The caſtle has been frequently honoured with the preſence of ſovereigns, particularly Edward I. here received the oath of fealty from John Baliol of Scotland. It has been a formidable ſtructure, a great part of which is in ruins; the ſite of which, with its demeſnes, conſiſted of 1030 acres.

NORIA, a hydraulic machine much uſed in Spain. It conſiſts of a vertical wheel of 20 feet diameter, on the circumference of which are fixed a number of little boxes or ſquare buckets, for the purpoſe of raiſing the water out of the well, communicating with the canal below, and to empty it into a reſervoir above, placed by the ſide of the wheel. The buckets have a lateral orifice to receive and to diſcharge the water. The axis of this wheel is embraced by four ſmall beams, croſſing each other at right angles, tapering at the extremities, and forming eight little arms. This wheel is near the centre of the horſe walk, contiguous to the vertical axis, into the top of which the horſe beam is fixed: but near the bottom it is embraced by four little beams, forming eight arms ſimilar to thoſe above deſcribed, on the axis of the water wheel. As the mule which they uſe goes round, theſe horizontal arms, ſupplying the place of cogs, take hold, each in ſucceſſion, of thoſe arms which are fixed on the axis of the water wheel, and keep it in rotation.

This machine, than which nothing can be cheaper, throws up a great quantity of water; yet undoubtedly it has two defects: the firſt is, that part of the water runs out of the buckets and falls back into the well after it has been raiſed nearly to the level of the reſervoir: the ſecond is, that a conſiderable proportion of the water to be diſcharged is raiſed higher than the reſervoir, and falls into it only at the moment when the bucket is at the higheſt point of the circle, and ready to deſcend.

Both theſe defects might be remedied with eaſe, by leaving theſe ſquare buckets open at one end, making them ſwing on a pivot fixed a little above their centre of gravity, and placing the trough of the reſervoir in ſuch a poſition as to ſtop their progreſs whilſt perpendicular; make them turn upon their pivot, and ſo diſcharge their contents.

From the reſervoir the water is conveyed by channels to every part of the garden; theſe have diviſions and ſubdiviſions or beds, ſome large, others very ſmall, ſeparated from each other by little channels, into which a boy with his ſhovel or his hoe directs the water, firſt into the moſt diſtant trenches, and ſucceſſively to all the reſt, till all the beds and trenches have been either covered or filled with water.

Mr Townſend, from whom we have taken the above account, thinks, that on account of the extreme ſimplicity of this machine, it is an invention of the moſt remote antiquity. By means of it the inhabitants every morning draw as much water from the well as will ſerve through the day, and in the evening diſtribute it to every quarter according to the nature of their crops. The reſervoirs into which they raiſe the water are about 20, 30, or even 40 feet ſquare, and three feet high above the ſurface of the ground, with a ſtone cope on the wall, declining to the water for the women to waſh and beat their clothes upon.

Our limits preclude us from following Mr Townſend farther in the deſcription of a particular noria uſed at Barcelona; which he conceives to be the original chain pump, or at leaſt its parent. He compares it with ſimilar inſtruments, and ſhows its advantages and diſadvantages.

NORICUM (Ptolemy, Tacitus); a Roman province, ſituated between the Danube on the north, and thus ſeparated from ancient Germany; the Alpes Noricæ on the ſouth; the river Ænus on the weſt, which ſeparates it from Vindelicia; and Mons Cetius on the eaſt, which divides it from Pannonia. Now containing a great part of Auſtria, all Saltzburg, Stiria, and Carinthia. It was anciently a kingdom under its own kings (Cæſar, Velleius, Suetonius). *Norici* the people, ſubdued by Tiberius under Auguſtus, as allies of the Pannonii (Dio, Velleius). Tacitus reckons Noricum among thoſe provinces which were governed by procurators, officers ſent by the emperors to receive and diſpoſe of the public revenue according to order. It was divided into two provinces, but at what time uncertain; ſuppoſed as low down as Diocleſian and Conſtantine, *viz.* the *Noricum Ripenſe*, running along the ſouth ſide of the Danube; and the *Noricum Mediterraneum*, extending towards the Alps. How far each of theſe extended in breadth does not appear: all the account we have of the matter being from Sextus Rufus, and the *Notitia Imperii Occidentalis*. Anciently a country famous for its iron and ſteel (Horace); as is Stiria at this day, a part of Noricum. A climate cold, and more ſparingly fruitful (Solinus).

NORIN, a river which riſes in a corner of the Venetian confines, that runs between the rugged marble hills, and is left entirely to itſelf from its very ſource; hence a vaſt tract of land is overflowed by it, and encumbered with reeds, willows, and wild elders. A ſmall ſpace of ground only remains dry between the roots of the hills and the marſh at a place called *Prud*, and that is all covered with pieces of ancient hewn ſtones, fragments of inſcriptions, columns, and capitals, and baſs reliefs of the beſt age, worn and deformed by time, and the barbariſm of the northern people, who begun on that ſide to deſtroy Narona. The inhabitants, who go often to cut reeds in the marſh, aſſert, that the veſtiges of that large city may ſtill be ſeen under water. It appears to have been extended over the plain a great way, and undoubtedly it was three miles in length at the foot of the hills. The ancient road is now under water; and it is neceſſary to aſcend a very ſteep road, in order to paſs the point of a craggy hill, on which probably before the Roman times thoſe fortifications were erected that coſt Vatinius ſo much labour.

NORIS (Henry), cardinal, who was a great ornament of the order of the monks of St Auguſtine, was deſcended from the preſident Jaſon, or James de Noris, and born at Verona 1631. He was carefully educated by his father Alexander Noris, originally of Ireland, and well known by his Hiſtory of Germany. He diſcovered from his infancy an excellent underſtanding, great vivacity, and a quick apprehenſion. His father inſtructed him in the rudiments of grammar, and procured an able profeſſor of Verona, called *Maſſoleini*, to be his preceptor. At 15 he was admitted a penſioner in the Jeſuits college at Rimini, where he ſtudied philoſophy; after which he applied himſelf to the writings of the fathers of the church, particularly thoſe of St Auguſtine: and taking the habit in the convent of the Auguſtine monks of Rimini, he diſtinguiſhed himſelf among that fraternity in a ſhort time by his erudition: inſomuch, that as ſoon as he was out of his noviciate or time of probation, the general of the order ſent for him to Rome, in order to give him an opportunity of improving himſelf in the more ſolid branches of learning. He did not diſappoint his ſuperior's expectations. He gave himſelf up entirely to his ſtudy, and ſpent whole days, and even nights, in the library of the Angeliques of St Auguſtine. His conſtant courſe [illegible] to ſtick to his books 14 hours a day; and this courſe he continued till he became a cardinal. By this means he became qualified to inſtruct others; and on this errand he was ſent firſt to Pezaro, and thence to Perouſa, where he took his degree of doctor of divinity; after which proceeding to Padua, he applied himſelf to finiſh his Hiſtory of Pelagianiſm. He had begun it at Rome at the age of 26; and having completed his deſign, the book was printed at Florence and publiſhed in 1673. The great duke of Tuſcany invited him the following year to that city, made him his chaplain, and profeſſor of eccleſiaſtical hiſtory in the univerſity of Piſa, which his highneſs had founded with that view.

In his hiſtory he ſet forth and defended the condemnation pronounced, in the eighth general council, againſt Origen and Mopſueſta, the firſt authors of the Pelagian errors: he alſo added an account of the Schiſm of Aquileia, and a Vindication of the Books written by St Auguſtine againſt the Pelagians and Semi-Pelagians. The work had procured him a great reputation, but met with ſeveral antagoniſts, to whom he publiſhed proper anſwers: the diſpute grew warm, and was carried before the ſovereign tribunal of the inquiſition. There the hiſtory was examined with the utmoſt rigour, and the author diſmiſſed without the leaſt cenſure. It was reprinted twice afterwards, and Mr Noris honoured by Pope Clement X. with the title of Qualificator of the Holy Office. Notwithſtanding this, the charge was renewed againſt the Pelagian Hiſtory, and it was dilated afreſh before the inquiſition in 1676; but it came out again with the ſame ſucceſs as at firſt. Mr Noris was now ſuffered to remain in peace for ſixteen years, and taught eccleſiaſtical hiſtory at Piſa, without any moleſtation, till he was called to Rome by Innocent XII. who made him under-librarian of the Vatican in 1692. This poſt was the way to a cardinal's hat; his accuſers therefore took freſh fire, and publiſhed ſeveral new pieces againſt him. Hence the Pope appointed ſome learned divines, who had the character of having taken neither ſide, to re-examine Father Noris's books, and make their report of them. Their teſtimony was ſo advantageous to the author, that his holineſs made him counſellor of the inquiſition. Yet neither did this hinder one of his adverſaries, the moſt formidable on account of his erudition, to riſe up againſt him, and attack him warmly, under the aſſumed title of a *Scrupulous Doctor of the Sorbonne*. Noris tried to remove theſe ſcruples in a work which appeared in 1695, under the title of An Hiſtorical Diſſertation concerning one of the Trinity that ſuffered in the Fleſh; wherein, having juſtified the monks of Scythia, who made uſe of that expreſſion, he vindicated himſelf alſo from the imputation of having attainted the Pope's infallibility, of hav g abuſed Vincentius Lirinenſis, and other biſhops Gaul, as favourers of Semi-Pelagianiſm, and of ha g himſelf gone into the errors of the biſhop of Ypre

H anſwers to all theſe accuſations were ſo much to t ſatisfaction of the pope, that at length his holine honoured him with the purple in 1695. After thi he was in all the congregations, and employed in th moſt important affairs; ſo that he had little time to pend in his ſtudy, a thing of which he frequently c mplained to his friends. Upon [illegible] death of Cardin Caſanati, he was made chief library keeper of the atican in 1770; and two years afterwards nominated, mong others, to reform the kalendar: but he died at Rome in 1704 of a dropſy. He was one of the moſt learned men in the laſt century: his writings abound with erudition, and are very elegantly finiſhed. He was a member of the Academy; whence he aſſumed the name of Eucrates Agoretico. His works are numerous, and were publiſhed at Verona, in 1729 and 1730, in five volumes folio.

NORKOPING, a town of Sweden, in the province of Eaſt Gothland, in eaſt longitude 15° 30′, latitude 58° 20′. Its name ſignifies "the northern market," in the Swediſh language. It ſtands on the banks of a large river called *Motala*, which coming from the lake *Vetter*, falls a little lower into a gulf called *Brawiken*. It is the largeſt and moſt populous town in Sweden, next to Stockholm, conveniently ſituated near the [illegible] a navigable river, which brings large veſſels up to the middle of the town. There are ſome handſome ſtreets, and the houſes in general are neatly built. Some of the churches are worth ſeeing; but the greateſt curioſity are the famous copper mines, where there is a vaſt number of people conſtantly at work. In this article the town carries on a very good trade; as alſo in ſeveral other manufactures, as leather, ſteel, and guns, which they make the beſt in Sweden.

[illegible] large ſpace of ground, being ten miles [illegible] but the houſes are ſmall and ſcattered, [illegible] the inhabitants do not exceed 10,000. The river Motala flows through the town, forms a ſeries of cataracts, and is divided into four principal ſtreams, which encircle ſeveral rocky iſlands, covered with houſes and manufactories. At the extremity of the town it is navigable for ſmall veſſels. Several manufactories are eſtabliſhed in the town; 55 fabrics of cloth, which employ 1500 men; 3 ſugar-houſes; 1 of ſnuff; 50 mills for grinding corn, which is exported in large quantities; and a braſs foundery. A ſalmon fiſhery gives employment and riches to many of the inhabitants.

NORMANDY, a province of France, bounded on the north by the Engliſh channel; on the eaſt by Picardy and the Iſle of France; o the ſouth by Perche and Maine, and one part of Bretagne; and on the weſt by the ocean. In is about 155 miles in length, 85 in breadth, and 600 in circumference. It is one of the moſt fertile, aud brings in the largeſt revenue of the kingdom. It abounds in all things except wine, but they ſupply that defect by cyder and perry. There are vaſt meadows, fat paſtures, and the ſea yields plenty of fiſh. It contains iron, copper, and a great number of rivers and harbours. It carries on a great trade, is very populous, and comprehends a vaſt number of towns and villages. It is divided into the Upper and Lower; the Upper borders upon Picardy, and the Lower upon Bretagne. It contains ſeven dioceſes or biſhoprics, Rouen, Bayeux, Avranches, Evreux, Sées, Liſieux, and Coutances, in which they compute [illegible] pariſhes, and 80 abbeys. The inhabitants [illegible] ions, and capable of underſtanding any arts and ſciences; but they are chiefly fond of law. The Normans, a people of Denmark and Norway, having entered France under Rollo, Charles the Simple ceded this country to them in 912, which from that time was called *Normandy*, and contains about 8200 ſquare miles. Its chief city is Rouen. Rollo was the firſt duke, and held it as a fief of the crown of France, and ſeveral of his ſucceſſors after him, till William, the ſeventh duke, conquered England in 1066: from which time it became a province of England, till it was loſt in the reign of King John, and reunited to the crown of France; but the Engliſh ſtill keep the iſlands on the coaſts of Normandy.

The principal rivers are the Seine, the Eure, the Aure, the Iton, the Dive, the Andelle, the Rille, the Touque, the Drômee, and the Orne: among the ſea ports, the principal are thoſe of Dieppe, Havre, Honfleur, Cherburg, and Granville. Rouen is the principal city.

NORMANS, a fierce warlike people of Norway, Denmark, and other parts of Scandinavia. They at different times overran and ravaged moſt countries in Europe: to the reſpective hiſtories of thoſe countries we therefore refer for a fuller account of them, as it is impoſſible to enlarge upon particulars in this place without repeating what has been already ſaid, or may be ſaid, in different parts of the work.

Norman Characters, a ſpecies of writing introduced into England by William I. From ſome old manuſcripts the Norman writing appears to have been compoſed of letters nearly Lombardic. In regal grants, charters, public inſtruments, and law proceedings, this character was uſed with very little variation from the reign of the Conqueror to that of Edward III. See Writing.

NORRIS, or Noris. See Noris.

NORRIS (John), a learned Engliſh divine and Platonic philoſopher, was born in 1657 at Collingborne-Kingſton, in Wiltſhire, of which place his father Mr John Norris was then miniſter. He bred his ſon firſt at Wincheſter ſchool, and afterwards ſent him to Exeter college in Oxford, where he was admitted in 1676; but was elected fellow of All Souls in 1680, ſoon after he had taken his degree of bachelor of arts. From his firſt application to philoſophy, Plato became his favourite author; by degrees he grew deeply enamoured with the beauties of that divine writer, as he thought him; and took an early occaſion to communicate his ideal happineſs to the public, by printing an Engliſh tranſlation of a rhapſody, under the title of The Picture of Love Unveiled, in 1682. He commenced maſter of arts in 1684, and the ſame year opened a correſpondence with that learned myſtic divine Dr Henry More of Chriſt's college in Cambridge. He had alſo a correſpondence with the learned Lady Maſham, Dr Cudworth's daughter, and the ingenious Mrs Aſtell. He reſided at his college, and had been

Norris, North.

in holy orders five years, when he was preſented to the rectory of Newton St Loe, in Somerſetſhire, 1689; upon which occaſion he married and reſigned his fellowſhip. In 1691, his diſtinguiſhed merit procured him the rectory of Bemerton, near Sarum. This living, upwards of 200l. a-year, came very ſeaſonably to his growing family; and was the more acceptable, for the eaſineſs of the parochial duty, which gave him leiſure to make an addition to his revenues by the fruits of his genius; the activity of which produced a large harveſt, that continued increaſing till 1710. But this activity ſeems to have become fatal to him; for towards the latter end of his life, he grew very infirm, and died in 1711, in his 54th year, at Bemerton. He was interred in the chancel of that church, where there is a handſome marble monument erected to his memory, with this inſcription: "H. S. E. Johannes Norris, parochiæ hujus rector, ubi annos viginti bene latuit curæ paſtorali et literis vacans, quo in receſſu ſibi poſuit latè per orbem ſparſa ingenii paris ac pietatis monumenta. Obiit an. Dom. 1711, ætatis 54." As to his character, he had a tincture of enthuſiaſm in his compoſition, which led him to imbibe the principles of the idealiſts in philoſophy, and the myſtics in theology; and the whole turn of his poetry ſhows, that this enthuſiaſm alone made him a poet. As an idealiſt, he oppoſed Locke, and adorned Malebranche's opinion, of ſeeing all things in God, with all the advantages of ſtyle and perſpicuity of expreſſion. In ſhort, his errors, which are harmleſs enough of themſelves, ought to be eaſily pardoned, on account of the general excellence of his writings, eſpecially upon ſubjects of practical divinity, which are univerſally eſteemed.

NORTH, one of the four cardinal points of the world; being that point of the horizon which is directly oppoſite to the ſun in meridian. The north wind is generally accompanied with a conſiderable degree of cold. It ſometimes blows with almoſt irreſiſtible fury. It is often mentioned by the claſſic authors under the name of *Boreas*, which is of Greek original. See Boreas.

North Pole. See Pole.

North (Dudley, lord), the third baron of that accompliſhed family, was one of the fineſt gentlemen in the court of King James; but in ſupporting that character, diſſipated and gamed away the greateſt part of his fortune. In 1645, he appears to have acted with the parliament; and was nominated by them to be adminiſtrator of the admiralty, in conjunction with the great earls of Northumberland, Eſſex, Warwick, and others. He lived to the age of 85, the latter part of which he paſſed in retirement; and wrote a ſmall folio of miſcellanies, in proſe and verſe, under this title, A Foreſt promiſcuous of ſeveral Seaſons Productions, in four parts, 1659.

North (Dudley, lord), ſon of the former, was made knight of the Bath in 1616, at the creation of Charles prince of Wales; and ſat in many parliaments, till excluded by the prevailing party in that which condemned the king. From that period Lord North lived privately in the country, and towards the end of his life entertained himſelf with books, and, as his numerous iſſue required, with economy; on which he wrote a little tract, called *Obſervations and advices economical*, 12mo. His other works are, Paſſages relating to the long parliament; the hiſtory of the life of Lord Edward North, the firſt baron of the family, addreſſed to his eldeſt ſon; and a volume of Eſſays.

North.

North (Francis lord Guildford, lord-keeper of the great ſeal in the reigns of Charles II. and James II.) was a third ſon of the ſecond Dudley lord North, baron of Kertling; and ſtudied at St John's college in Cambridge, from whence he removed to the Middle Temple. He acquired French, Italian, Spaniſh, and Dutch; and became not only a good lawyer, but was well verſed in hiſtory, mathematics, philoſophy, and muſic. He was afterwards made the king's ſolicitor-general, and was choſen to repreſent the borough of Lynn in parliament. He ſucceeded Sir Heneage Finch in the poſt of attorney-general; and Lord Chief Juſtice Vaughan, in the place of lord chief-juſtice of the common pleas. He was afterwards made keeper of the great ſeal: and in 1683 was created a baron, by the title of *Lord Guildford*. He died at his houſe at Wroxton in 1685. He wrote a philoſophical eſſay on muſic: a paper on the gravitation of fluids, conſidered in the bladders of fiſhes, printed in Lowthorp's abridgement of the Philoſophical Tranſactions; and ſome other pieces.

North (Right Hon. Frederick), earl of Guildford, Lord North, lord warden and admiral of the Cinque Ports, governor of Dover caſtle, lord lieutenant and cuſtos rotulorum of Somerſetſhire, chancellor of the univerſity of Oxford, recorder of Glouceſter and Taunton, an elder brother of the Trinity houſe, preſident of the Foundling hoſpital and of the Aſylum, a governor of the Turkey Company and of the Charter houſe, K. G. and LL. D. was born April 13. 1732; and married, May 20. 1756, Miſs Ann Speke, an heireſs of the ancient family of Dillington in Somerſetſhire, by whom he has left two ſons and three daughters: the eldeſt ſon George Auguſtus, born Sept. 11. 1757, and married, Sept. 30. 1785, to Miſs Hobart, ſucceeds to the earldom and eſtates. The late earl ſucceeded his father Auguſt 4. 1790. His lordſhip ſucceeded the celebrated Mr Charles Townſend as manager of the houſe of commons and chancellor of the exchequer; and in 1770, on the reſignation of the duke of Grafton, was made firſt lord of the treaſury; in which office he continued until the cloſe of the American war, or rather until the formation of the Rockingham miniſtry, which began the buſineſs of peace with the colonies. He was a man of ſtrong mental faculties; and as an orator, at once commanded attention and enforced conviction: but taking the helm at a time when the king's party were unpopular, and when it was ſuppoſed that the late earl of Bute was the great machine by which the cabinet was moved, ſo he continued in that ſtate of unpopularity until he reſigned the ſeals. During the whole of his premierſhip (and to conduct the helm at that time required uncommonly great abilities) he ſtudiouſly avoided impoſing any taxes that ſhould materially affect the lower claſs of people. The luxuries, and not the neceſſaries, of life were repeated objects of his budget. As a financier, he ſtood high, even in the opinion of oppoſition; and they were a combination of all the great talents in the kingdom, but, fatally wedded to the deſtructive plan of ſubduing the

North
||
North-weſt
Paſſage.

republican ſpirit of the Americans, his adminiſtration will not only ſtand marked in the page of hiſtory with an immenſe waſte of public treaſure, but it will appear beſprinkled with the kindred blood of thouſands of Britiſh ſubjects. To the very laſt moment he ſpoke in the ſenate, however, he defended that war; and ſaid, he was then, as he was formerly, prepared to meet the minuteſt inveſtigation as to his conduct in that buſineſs; which nothing but the unforeſeen intervention of France could have prevented from being crowned with ſucceſs. His lordſhip was one of the firmeſt and moſt ſtrenuous ſupporters of the conſtitution in church and ſtate. He died on the 5th of Auguſt 1792. His recollection he retained to his laſt moments: his family, except Lord North, who came within a few minutes afterwards, were aſſembled round his bed, and he took leave of them individually. Their grief did not ſuffer them to leave the room for ſome time after the event; and Lady Caroline Douglas was at laſt forced from it. Even Dr Warren, who muſt be ſtrengthened as far as habit can operate againſt nature to endure ſuch ſcenes, ran from this, convulſed with ſorrow. If any extent of ſympathy can leſſen affliction, this family may find ſuch relief; for perhaps no man was ever more generally beloved by all who had acceſs to him than the earl of Guildford.

We may form an opinion of the eſtimation the celebrated univerſity of Oxford entertained of their chancellor while living, by the very great honour they paid to his remains. About five o'clock in the afternoon of the 15th, the great bell at St Mary's church at Oxford rang out, which was a ſignal that the funeral proceſſion had arrived in the environs of that city. The officers of the univerſity, and the whole body of reſident ſtudents, were previouſly aſſembled in Magdalen College, in order to pay ſome tribute to the memory of their deceaſed chancellor. They joined the proceſſion at Magdalen Bridge, and paraded on foot before the herſe up the high ſtreet to Carfax; from thence down the corn market to St Giles's church at the town's end, in a moſt ſolemn manner. Here they halted, and opening to the right and left, the herſe and other carriages paſſed through, the whole univerſity being uncovered. The herſe and attendants then proceeded to Banbury, where his lordſhip's remains were depoſited in the family vault.

North Cape, the moſt northerly promontory in Europe, on the coaſt of Norway. E. Long. 21. 0. N. Lat. 78. 0.

North Ferry, a ſmall village, on the north ſide of the frith of Forth, at the Queen's Ferry paſſage. There was here formerly a chapel, ſerved by the monks of Dunfermline, and endowed by Robert I. Near it are large granite quarries, which partly ſupply London with paving ſtones, and employ many veſſels for the conveyance. "The granite (Mr Pennant ſays) lies in perpendicular ſtrata, and above is a reddiſh earth, filled with micaceous friable nodules."

North Foreland, a cape or promontory of Kent, in the iſle of Thanet, four miles eaſt of Margate. Between this and the South Foreland are the Downs, through which all ſhips paſs that are bound to or from the weſt. E. Long. 1. 25. N. Lat. 51. 25.

North-Weſt Paſſage, a paſſage to the Pacific ocean through Hudſon's bay or Davis's ſtraits, and which hath been frequently attempted without ſucceſs; notwithſtanding which, many people are ſtill of opinion that it is practicable.

The idea of a paſſage to the Eaſt Indies by the north pole, or through ſome opening near to it, was ſuggeſted as early as the year 1527. The perſon who had the honour to conceive this idea was Robert Thorne, a merchant of Briſtol, who addreſſed two papers on the ſubject, the one to King Henry VIII. the other to Dr Ley, ambaſſador from that monarch to the emperor Charles V. To remove any objection to the undertaking, which might be drawn from the ſuppoſed danger, he inſiſts, in his addreſs to the king, upon the great advantages of conſtant daylight in the polar ſeas, and the probability of the climate being in thoſe regions temperate during the ſummer months. In the paper addreſſed to Dr Ley, he obſerves that coſmographers may as probably be miſtaken in the opinion which they entertain of the polar regions being impaſſable from extreme cold, as it has been found they were in ſuppoſing the countries under the line to be uninhabitable from exceſſive heat.

The poſſibility of the paſſage was, in conſequence of theſe addreſſes, very generally ſuppoſed; and in 1557, Sir Martin Forbiſher ſailed to 62 north latitude, where he diſcovered the ſtraits which have ſince bore his name. In 1577, Barne, in a book entitled the *Regiment of the Sea*, mentions a north-weſt paſſage as one of the five ways to Cathay; and dwells on the mildneſs of the climate, which, from the conſtant preſence of the ſun during ſummer, he imagines muſt be found near the pole. In 1578, George Beſt, a gentleman who had been with Sir Martin Forbiſher in his voyages of diſcovery, wrote a very ingenious diſcourſe to prove all parts of the world habitable. It does not, however, appear that any voyage was undertaken, for the expreſs purpoſe of attempting to ſail to India in a north-weſt direction, till the year 1607, when Henry Hudſon was ſent, at the expence of ſome merchants in London, to diſcover a paſſage by the north pole to Japan and China. He ſailed from Graveſend on the 1ſt of May, and on the 21ſt of June fell in with the land to the weſtward, in latitude 73, which he named *Hold-with-hope*. On the 27th he diſcovered Spitſbergen, and met with much ice. The higheſt latitude in which he made an obſervation was 80° 27'. See Hudson.

In March 1609, Jones Poole was ſent by Sir Thomas Smith, and the reſt of the Muſcovy Company, to make further diſcoveries towards the north pole. After great ſeverity of weather, and much difficulty from ice, he made the ſouth part of Spitſbergen on the 16th of May; and ſailing along and ſounding the coaſt, he made many accurate diſcoveries; but was not in that voyage able to proceed beyond 79° 50'. He was again employed (1611), in a ſmall veſſel called the *Elizabeth*, to attempt the north-weſt paſſage; but after ſurmounting numberleſs difficulties, and penetrating to 80° of latitude, he loſt his ſhip at Spitſbergen. Two voyages, equally unſucceſsful, were made in 1614 and 1615, by Baffin and Fotherby; the latter of whom concludes the account of his diſcoveries and dangers, with exhorting the company which employed him not to adventure more than 150l. or 200l. at moſt on yearly voyages to theſe ſeas.

Hitherto nothing had been done in this great undertaking but by private adventurers, fitted out for the

North-weſt Paſſage.

the double purpoſe of diſcovery and preſent advantage; and the polar regions were ſuffered to remain unexplored in that direction, from the year 1615 till 1773 when the earl of Sandwich, in conſequence of an application which had been made to him by the Royal Society, laid before his majeſty a propoſal for an expedition to try how far navigation is practicable towards the north pole. Upon receiving this propoſal, his majeſty was pleaſed to direct that the voyage ſhould be immediately undertaken, with every aſſiſtance that could contribute to its ſucceſs. Accordingly, the Racehorſe and Carcaſs bombs were fitted out for the purpoſe, and the command of the expedition given to Captain Phipps, now Lord Mulgrave. His Lordſhip's inſtructions were to proceed up to the pole, or as far towards it as poſſible, and as nearly upon a meridian as the ice or other obſtructions ſhould admit; and during the courſe of the voyage, to make ſuch obſervations of every kind as might be uſeful to navigation, or tend to the promotion of natural knowledge. A very accurate account of this voyage was publiſhed by his Lordſhip in 1774. He had, by exerting all the powers of a ſkilful and intrepid ſeaman, forced his way, on the 1ſt of Auguſt, to 80° 37′; but could proceed no farther, as he was there oppoſed by one continued plain of ſmooth unbroken ice, bounded only by the horizon.

Many other attempts have been made to diſcover this paſſage, by ſailing along the weſtern coaſt of America; but hitherto none of them has been crowned with ſucceſs. So early as 1579, Sir Francis Drake aſſured Queen Elizabeth that he had ſailed ſome leagues up the ſtraits of Anian (ſee Anian), and diſcovered New Albion, to the north of California; but the ſtrait is now known to have no exiſtence; and Drake's real diſcoveries were not improved. In 1638, King Charles I. ſent Captain Luke Fox in one of his pinnaces to attempt the paſſage; but of his proceedings we know nothing, but that he reached Port Nelſon in Hudſon's bay, where he found ſome remains of former navigators. Next year Captain James was fitted out by the merchants of Briſtol for the ſame purpoſe. James was one of the ableſt navigators that ever ſailed from England or any other country; and his voyages to the north were printed in 1633. After all the experiments he had made, he concluded that there was no ſuch paſſage; or if there be, he affirmed that the diſcovery of it would not be attended with thoſe advantages which are commonly expected. His reaſons, however, for theſe opinions have been anſwered, and many ſubſequent attempts have been made to perform what he thought impoſſible. The arguments for a north-weſt paſſage were ſo plauſible, that, in 1744, an act of parliament was paſſed to encourage the diſcovery of it. Among many others, Captain Cook attempted the diſcovery in vain, and thence adopted James's opinion. (See *Cook's Diſcoveries*, N° 103.) This celebrated navigator, after having proceeded northwards to the weſtern extremity of America, and aſcertained the proximity of the two great continents of Aſia and America, returned to the Sandwich iſlands, firmly perſuaded of the impracticability of a paſſage in that hemiſphere from the Atlantic into the Pacific ocean, either by an eaſtern or a weſtern courſe.

Later voyagers, however, have pretended to detect ſome errors in Cook's diſcoveries and the author of a ſmall tract, entitled *An authentic Statement of all the Facts relative to Nootka Sound*, goes a great way to make the diſcovery not yet hopeleſs. In his account of the expedition under the direction of Meſſrs Etches, he ſays, that "one of the firſt diſcoveries made by theſe ſhips was, that what was by the immortal Cook laid down as a continuation of the north-weſt continent of America, and lying between the northern latitudes of 48 and 57, is on the contrary an extenſive cluſter of unexplored iſlands inhabited by numerous tribes of friendly Indians, with whom a regular connexion was formed."

North-eaſt Paſſage.

Theſe iſlands they diſcovered, contrary to the aſſertion of Captain Cook, to conceal the opening of a vaſt inland ſea, or archipelago, in all probability equal to the Mediterranean or Baltic ſeas, and dividing the great northern continent of America. The Princeſs Royal penetrated ſome hundred leagues among them, in a north-eaſt courſe, to within 200 leagues of Hudſon's houſe, but had not then an opportunity to explore the extreme termination of that archipelago, their commercial concerns obliging them to return to the China market; but the commanders had the ſtrongeſt reaſons to believe, had the time favoured their ſurvey, that they ſhould have been able to diſcover the long wiſhed for paſſage between the Atlantic and South ſea. They conceived, that ſhould neither the inland arm of the ſea through which the Princeſs Royal penetrated, nor a large ſtrait named Sir Charles Middleton's about three degrees to the ſouthward, be found to reach acroſs the continent, yet that the land barrier muſt be very inconſiderable; and that at the extremity of this bay a practicable paſſage, either by rivers or lakes, will, by perſeverance, be found terminating towards Hudſon's bay.

Upon the whole, however, it appears to us extremely doubtful whether there be ſuch a paſſage; but it is much more likely to be diſcovered, if diſcovered at all, by the progreſſive advances of mercantile enterpriſe than by any immediate expedition undertaken for that purpoſe.

North-Eaſt Paſſage, a paſſage to the Eaſt Indies along the northern coaſts of Aſia, which, like the former, hath frequently been attempted, but hitherto without ſucceſs. The firſt attempt was made in 1553, by Sir Hugh Willoughby, who commanded three ſhips. He departed from the Thames and ſailed to the North Cape, where one of his ſhips left him, and returned home. The other two ſhips being ſeparated, Sir Hugh proceeded farther northward, and diſcovered that part of Greenland which the Dutch have ſince called *Spitzberg*; but the ſeverity of the cold obliging him to return to the ſouthward, he was forced, by bad weather, into the river Arzina, in Muſcovite Lapland, where, not being able to come out, he was found the next ſpring frozen to death, with all his ſhip's company; having the notes of his voyage and his laſt will lying before him, whereby it appeared that he lived till January. But Richard Chancellor, in the third ſhip, with better ſucceſs, in the meanwhile entered Wardhuys, where he waited ſome time for his companions to no purpoſe; uncertain whether they were loſt, or driven farther by ſtreſs of weather. He held a council on what he ſhould do; whether to

return,

North-eaſt Paſſage.

return, or purſue his voyage. Whatever danger might be in the laſt, every one agreed to it, that they might not ſeem to have leſs courage than their captain. They therefore ſet ſail, and in a few days found themſelves in a ſea where they could no longer perceive any night. This ſhip, wandering about, entered ſoon after into a large bay or gulf. Here they caſt anchor, in ſight of land; and while they were examining the coaſt, they diſcovered a fiſhing boat. Chancellor getting into his ſloop, went towards it; but the fiſhermen took to flight. He followed, and, overtaking them, ſhowed them ſuch civilities as conciliated their affections to him; and they carried him to the place where now is the famous port of St Michael the Archangel. Theſe people immediately ſpread through all the coaſts an account of the arrival of thoſe ſtrangers; and people came from ſeveral parts to ſee them, and aſk them queſtions. They, in their turn, examined the others, and found that the country they were in was Ruſſia, governed by the mighty emperor John Baſilowitz. Chancellor from Archangel travelled on ſledges to the Czar at Moſcow; from whom, overjoyed at the proſpect of opening a maritime commerce with Europe, he obtained privileges for the Engliſh merchants, and letters to King Edward VI. who was not, however, alive to receive them.

In 1585, Mr John Davis in two barks diſcovered Cape Deſolation, which is ſuppoſed to be part of Greenland; and two years after advanced as far as Lat. 72°, where he diſcovered the ſtrait which ſtill bears his name. To enumerate all the attempts which have been made to diſcover a north-eaſt paſſage, would ſwell the article to very little purpoſe. The Engliſh, Dutch, and Danes, have all attempted it without ſucceſs. The laſt voyage from England for this purpoſe was made in 1676, under the patronage of the duke of York. That unfortunate prince, who was on all occaſions earneſt for the promotion of commerce, and the Lord Berkeley, &c. fitted out a ſhip, commanded by Captain Wood, for an attempt once more to find a north-eaſt paſſage to India, accompanied with a ſhip of the king's. They were encouraged to this attempt, after it had been ſo long deſpaired of, by ſeveral new reports and reaſonings: ſome of which ſeem not to have been very well grounded—As,

"1. On the coaſt of Corea, near Japan, whales had been found with Engliſh and Dutch harpoons ſticking in them. This is no infallible proof that ſhips could get thither by a north-eaſt paſſage, although whales might.

"2. That, 20 years before, ſome Dutchmen had ſailed within one degree of the north pole, and found it temperate weather there: and that therefore William Barents, the Dutch navigator who wintered at Nova Zembla in the year 1596, ſhould have ſailed further to the north before turning eaſtward; in which caſe, ſaid they, he would not have found ſo much obſtruction from the ice.

"3. That two Dutch ſhips had lately ſailed 300 leagues to the eaſtward of Nova Zembla; but their Eaſt India Company had ſtifled that deſign, as againſt their intereſt:—and ſuch like other airy reports. But this attempt proved very unfortunate. They doubled the North Cape, and came among much ice and drift wood, in 76° of north latitude, ſteering to the coaſt of Nova Zembla, where the king's ſhip ſtruck upon the rocks, and was ſoon beat to pieces; and Captain Wood returned home with an opinion, "that ſuch a paſſage was utterly impracticable, and that Nova Zembla is a part of the continent of Greenland."

Theſe paſſages, however, are not yet deemed impracticable by all. The Count de Buffon holds it for certain, that there is a paſſage from Europe to China by the north ſea. The reaſon why it has been ſo often attempted in vain, he thinks, is, that fear prevented the undertakers from keeping at a ſufficient diſtance from land, and from approaching the pole, which they probably imagined to be an immenſe rock. Hence he affirms, that if any farther attempts be made to find a paſſage to China and Japan by the north ſeas, it will be neceſſary to keep at a diſtance from the land and the ice; to ſteer directly towards the pole; and to explore the moſt open ſeas, where unqueſtionably, ſays he, there is little or no ice. This opinion has been lately revived by the Hon. Daines Barrington, who ſays, that if the paſſage be attempted by the pole itſelf, he has very little doubt of its being accompliſhed. See *North-Pole*.

Northampton.

NORTHAMPTON, a town in England, capital of a county of the ſame name, ſituated in W. Long. 0. 55. N. Lat. 52. 15. According to Camden, it was formerly called *North-afandon*, from its ſituation to the north of the river Nen, called anciently *Afona*, by which and another leſſer river it is almoſt encloſed. Dr Gibſon ſays, that the ancient Saxon annals called both it and Southampton ſimply *Hamton*; and afterwards, to diſtinguiſh them, called the one, from its ſituation, *Southamton*, and the other *Northamton*; but never *North-afandon*. Though it does not appear to be a place of very great antiquity, nor to have emerged from obſcurity till after the Conqueſt, it has ſent members to parliament ſince the reign of Edward I. and being in the heart of the kingdom, ſeveral parliaments have been held at it. There was alſo a caſtle, and a church dedicated to St Andrew, built by Simon de Sancto Licio, commonly called *Senlez*, the firſt earl of Northampton of that name. It is ſaid to have been burnt down during the Daniſh depredations; but in the reign of St Edward it appears to have been a conſiderable place. It was beſieged by the barons in their war with King John; at which time that military work called *Hunſhill*, is ſuppoſed to have been raiſed. In the time of Henry III. it ſided with the barons, when it was beſieged and taken by the king. Here the bloody battle was fought in which Henry VI. was taken priſoner. It was entirely conſumed by a moſt dreadful fire in 1675; yet, by the help of liberal contributions from all parts of the country, it hath ſo recovered itſelf, that it is now one of the neateſt and beſt built towns of the kingdom. Among the public buildings which are all lofty, the moſt remarkable are the church called *All-hallows* (which ſtands at the meeting of four ſpacious ſtreets), the ſeſſions and aſſize houſe, and the George inn, which belongs to the poor of the town. A county hoſpital or infirmary has been lately built here, after the manner of thoſe of Bath, London, Briſtol, &c. It has a conſiderable manufacture of ſhoes and ſtockings; and its fairs are noted for horſes both for draught and ſaddle; beſides, it is a great thoroughfare for the north and weſt roads. It was formerly walled, and had ſeven churches within and two without. The horſe market is reckoned to exceed all others in the kingdom, it being deemed the centre of all its horſe markets and horſe fairs, both for ſaddle and harneſs, and the chief rendezvous of the jockies both from York and London. Its principal manufacture is ſho[illegible] which great numbers are ſent beyond ſea; and the next to that, ſtockings and lace, as we have hinted at above. It is the richer and more populous, by being a thoroughfare both in the north and weſt roads; but, being 80 miles from the ſea, it can have no commerce by navigation. The walls of this town were above two miles in compaſs. It is ſuppoſed to contain about 1083 houſes, and 5200 inhabitants. It had formerly a nunnery in the neighbouring meadows, with ſeveral other monaſteries; and of its very old caſtle on the weſt ſide of the town, a ſmall part of the ruins are ſtill to be ſeen. Some diſcontented ſcholars came hither from Oxford and Cambridge, about the end of the reign of Henry III. and, with the king's leave, proſecuted their ſtudies here academically for three years; during which there was the face of an univerſity, till it was put a ſtop to by expreſs prohibition, becauſe it was a damage to both univerſities. The public horſe races are on a neighbouring down, called *Pye-Leys*. In and about the town are abundance of cherry gardens. Within half a mile of the town is one of the croſſes erected by King Edward I. in memory of his queen Eleanor, whoſe corpſe was reſted there in its way to Weſtminſter. On the north ſide of the river, near that croſs, many Roman coins have been ploughed up. At Guileſborough, north-weſt of Northampton, are to be ſeen the veſtiges of a Roman camp, the ſituation of which is the more remarkable, as lying between the Nen and the Avon, the only paſs from the north to the ſouth parts of England not intercepted by any river. This camp was ſecured only by a ſingle intrenchment, which was, however, very broad and deep.

Northamptonshirf, a county of England, is ſituated in the very heart of the kingdom: bounded on the eaſt by the counties of Bedford and Huntingdon; on the ſouth by thoſe of Buckingham and Oxford; on the weſt by Warwickſhire; and on the north by the counties of Leiceſter, Rutland, and Lincoln, which are ſeparated from it by the Leſſer Avon, and the Welland. Its greateſt length is about 50 miles, its greateſt breadth about 20, and its circumference about 130. It contains 330 pariſhes. There are in it one city, 11 market towns, 25,000 houſes, and 150,000 inhabitants. Nine members are returned to parliament for this county, viz. two knights for the ſhire, two for the city of Peterborough, two for each of the towns of Northampton and Brockly, and one for Higham Ferrers. It lies in the mid-land circuit, and in the dioceſe of Peterborough. As this county is dry, well cultivated, free from marſhes, except the fens about Peterborough, in the centre of the kingdom, and of courſe at a diſtance from the ſea, it enjoys a very pure and wholeſome air. In conſequence of this it is very populous, and ſo full of towns and churches, that 30 ſpires or ſteeples may be ſeen in many places at one view; and even in the fens, the inhabitants ſeem to enjoy a good ſtate of health, and to be little affected by the water which frequently overflows their grounds, eſpecially in winter, but is never ſuffered to remain long upon it. Its ſoil is exceeding fertile both in corn and paſturage; but it labours under a ſcarcity of fuel, as it doth not produce much wood, and, by lying at a diſtance from the ſea, cannot be eaſily ſupplied with coal. Its commodities, beſides corn, are ſheep, wool, black cattle, and ſaltpetre; and its manufactures are ſerges, tammies, ſhalloons, boots, and ſhoes. Beſides many leſſer brooks and ſtreams, it is well watered by the rivers Nen, Welland, Ouſe, and Leam; the three firſt of which are large, and for the moſt part navigable.

NORTHAMPTON, a county of North America, in Virginia, forming the ſouth part of the peninſula on the eaſtern coaſt of Virginia.

NORTH rocks, (otherwiſe called *St Patrick's rocks*, from a ſeat of ſtone amongſt them called *St Patrick's chair*, whence the rocks have taken this ſecond name; ſituated in the harbour of Donaghadee, in the county of Down, and province of Ulſter, in Ireland. From north to ſouth they are about two thirds of a league, between which is clean good ground. But care muſt be taken of the ſouth rock, on which many ſhips have periſhed: for it is overflowed by every tide, and no crew can ſave their lives if the wind blows high. This rock ſtands a full mile from the ſhore.

NORTH Sea. See *North Sea*.

NORTHERN lights, the ſame with Aurora Borealis, under which article we have given a copious account of this phenomenon, and of the ſuppoſed cauſes of it. Natural ſcience, however, does not arrive at perfection at once, and it is well if it does ſo after trials repeated for years with care and accuracy. How far the cauſes that have been aſſigned for this appearance will account for it, or whether they will be able to remove all difficulties, it is not for us to determine; but it is the part of philoſophers to hear all ſides, and to attend with patient aſſiduity to every hypotheſis, rejecting or receiving as reaſon, after the ſtricteſt inveſtigation, ſhall ſeem to favour the one ſide or the other. Wiſhing to lay before our readers every thing important either in ſcience or in literature, we cannot let paſs the opportunity which the preſent article affords us, of mentioning a hypotheſis which Doctor Stearns, an American, formed, about the year 1788, to account for the appearances called *aurora borealis*, and *aurora auſtralis*. For this laſt, ſee Aurora Borealis, N° 3.

Doctor Stearns ſuppoſes that theſe phenomena originate from aqueous, nitrous, ſulphureous, bituminous, and other exhalations, from the fumes of various kinds of earths or other minerals, vegetables, animals, fires, volcanoes, &c. Theſe, he thinks, become rarefied, and being charged with electrical fluid, become ſpecifically lighter than the circumambient air; hence, of courſe, they aſcend; and being elevated to the upper regions of the air, and driven by the winds from warmer to colder climates, the cold makes them combine and ſtiffen. When they are afterwards agitated by different currents of air, they ſparkle and crackle like the hairs of cats and other animals when ſtiffened with cold. This coruſcation in quite cold atmoſpheres, and in thoſe which are more temperate, appears in different poſitions in the horizon, zenith, or otherwiſe, according to the ſituation of the ſpectator, and the poſition of the elevated exhalations. The difference of colours the Doctor ſuppoſes to ariſe from the different qualities of the articles combined, thoſe of the moſt inflammable nature ſhining with the greateſt luſtre.

The Doctor likewiſe tries to account for theſe lights not appearing, or but ſeldom appearing, in ancient times. The atmoſphere, he thinks, was not impregnated with materials proper to produce them. He imagines that the increaſed conſumption of fuel, in America in particular, the burning of volcanoes, and the approach of blazing ſtars, whoſe atmoſpheres have been ſo expanded by the ſun's heat that part of them have fallen into the earth's atmoſphere, and communicated to it new matter, have ſo changed and prepared our air, that whenever its conſiſtence is proper, then, if the light of the ſun and moon is not too powerful, the aurora borealis will appear.

NORTHUMBERLAND, the moſt northerly county of England, and formerly a diſtinct kingdom, is bounded on the north and weſt by the river Tweed, which divides it from Scotland, the Cheviot hills, and part of Cumberland; waſhed on the eaſt by the German ocean; and ſeparated from Durham on the ſouth by the rivers Tyne and Derwent. This county, which gives the title of *duke* to a nobleman who married the daughter of Algernon duke of Somerſet, whoſe mother was heireſs of the Piercy family, extends about 66 miles in length from north to ſouth, and about 47 in breadth from eaſt to weſt. It is remarkably populous, containing 12 market towns, 280 villages, and 460 pariſhes. The face of the country, eſpecially towards the weſt, is roughened with huge mountains, the moſt remarkable of which are the Cheviot hills, and the high ridge called *Rideſdale;* but the lands are level towards the ſea ſide and the borders of Durham. The climate, like that of every other mountainous country in the neighbourhood of the ſea, is moiſt and diſagreeable: the air, however, is pure and healthy, as being well ventilated by breezes and ſtrong gales of wind; and in winter mitigated by the warm vapours from the two ſeas, the Iriſh and the German ocean, between which it is ſituated. The ſoil varies in different parts of the county. Among the hills it is barren; though it affords good paſture for ſheep, which cover thoſe mountains. The low country, when properly cultivated, produces plenty of wheat, and all ſorts of grain; and great part of it is laid out in meadow lands and rich encloſures. Northumberland is well watered with many rivers, rivulets, and fountains: its greateſt rivers are the Tweed and the Tyne. The Tyne is compoſed of two ſtreams called *South* and *North Tyne:* the firſt riſes on the verge of Cumberland, near Alſton Moor; enters Northumberland, running north to Haltweſel; then bends eaſterly, and receiving the two ſmall rivers Eaſt and Weſt Alon, unites above Hexham with the other branch, taking its riſe at a mountain called *Fane-head* in the weſtern part of the county, thence called *Tine-dale;* is ſwelled in its courſe by the little river Shele; joins the Read near Billingham; and running in a direct line to the ſouth-eaſt, is united with the ſouthern Tyne, forming a large river that waſhes Newcaſtle, and falls into the German ocean near Tinmouth.

In all probability the mountains of Northumberland contain lead ore and other mineralized metals in their bowels, as they in all reſpects reſemble thoſe parts of Wales and Scotland where lead mines have been found and p[illegible]ed. Perhaps the inhabitants are diverted from [illegible] of this nature, by the certain profits and co[illegible]employment they enjoy in working the coal pits, with which this county abounds. The city of London and the greateſt part of England, are ſupplied with fuel from theſe ſtores of Northumberland, which are inexhauſtible, enrich the proprietors, and employ an incredible number of hands and ſhipping. About 658,858 chaldrons are annually ſhipped for London.

There are no natural woods of any conſequence in this county; but many plantations belonging to the ſeats of noblemen and gentlemen, of which here is a great number. As for pot herbs, roots, ſalading, and every article of the kitchen garden and orchard, they are here raiſed in great plenty by the uſual means of cultivation; as are alſo the fruits of more delicate flavour, ſuch as the apricot, peach, and nectarine. The ſpontaneous fruits it produces in common with other parts of Great Britain, are the crab-apple, the ſloe or bullace, the hazel nut, the acorn, hips, and haws, with the berries of the bramble, the juniper, wood ſtrawberries, cranberries, and bilberries.

Northumberland raiſes a good number of excellent horſes and black cattle, and affords paſture for numerous flocks of ſheep; both the cattle and ſheep are of a large breed, but the wool is coarſer than that which the more ſouthern counties produce. The hills and mountains abound with a variety of game, ſuch as red deer, foxes, hares, rabbits, heathcock, grouſe, partridge, quail, plover, teal, and woodcock: indeed, this is counted one of the beſt ſporting counties in Great Britain. The ſea and rivers are well ſtocked with fiſh; eſpecially the Tweed, in which a vaſt number of ſalmon is caught and carried to Tinmouth, where being pickled, they are conveyed by ſea to London, and ſold under the name of *Newcaſtle Salmon.*

The Northumbrians were anciently ſtigmatized as a ſavage, barbarous people, addicted to cruelty, and inured to rapine. The truth is, before the union of the two crowns of England and Scotland, the borderers on each ſide were extremely licentious and ungovernable, trained up to war from their infancy, and habituated to plunder by the mutual incurſions made into each kingdom; incurſions which neither truce nor treaty could totally prevent. People of a pacific diſpoſition, who propoſed to earn their livelihood by agriculture, would not on any terms remain in a country expoſed to the firſt violence of a bold and deſperate enemy; therefore the lands lay uncultivated, and in a great meaſure deſerted by every body but lawleſs adventurers, who ſubſiſted by theft and rapine. There was a tract 50 miles in length and 6 in breadth, between Berwick and Carliſle, known by the name of the *Debateable Land,* to which both nations laid claim, though it belonged to neither; and this was occupied by a ſet of banditti who plundered on each ſide, and what they ſtole in one kingdom, they ſold openly in the other:

nay, they were ſo dexterous in their occupation, that by means of hot bread applied to the horns of the cattle which they ſtole, they twiſted them in ſuch a manner, that, when the right owners ſaw them in the market, they did not know their own property. Wardens were appointed to guard the marches or borders in each kingdom; and theſe [illegible] always conferred on noblemen of the [illegible] for influence, valour, and integrity. The Engliſh border was divided into three marches, called the *eaſt*, *weſt*, and *middle marches*; the gentlemen of the country were conſtituted deputy wardens, who held march-courts, regulated the watches, diſciplined the militia, and took meaſures for aſſembling them in arms at the firſt alarm: but in the time of peace between the two nations, they were chiefly employed in ſuppreſſing the inſolence and rapine of the borderers. Since the union of the crowns, however, Northumberland is totally changed, both with reſpect to the improvement of the lands, and the reformation of the inhabitants. The grounds, being now ſecure from incurſion and inſult, are ſettled by creditable farmers, and cultivated like other parts of the kingdom. As hoſtilities have long ceaſed, the people have forgot the uſe of arms, and exerciſed themſelves in the more eligible avocations of peace; in breeding ſheep and cattle, manuring the grounds, working at the coal pits, and in different branches of commerce and manufacture. In their perſons they are generally tall, ſtrong, bold, hardy, and fleſh coloured; and though leſs unpoliſhed than their anceſtors, not quite ſo civilized as their ſouthern neighbours. The commonalty are well fed, lodged, and clothed; and all of them remarkably diſtinguiſhed by a kind of *ſhibboleth* or *wharle*, being a particular way of pronouncing the letter *R*, as if they hawked it up from the windpipe, like the cawing of rooks. In other reſpects, the language they ſpeak is an uncouth mixture of the Engliſh and Scottiſh dialects. There is no material diſtinction between the faſhionable people of Northumberland and thoſe of the ſame rank in other parts of the kingdom; the ſame form of education will produce the ſame effects in all countries. The gentlemen of Northumberland, however, are remarkable for their courage, hoſpitality, and hard drinking. The number of inhabitants is reckoned 126,400, of houſes 22,740.

A great number of Roman monuments have been found in this county; but the moſt remarkable curioſity of that kind conſiſts in the remains of Hadrian's vallum and the wall of Severus. See *Adrian*, note (a), and *Severus's Wall*.

The moſt noted towns in Northumberland, are Newcaſtle, Morpeth, Alnwick, Berwick, Hexham, and North Shields. It ſends two members to parliament.

NORTHWICK, a ſmall town of Cheſhire, long celebrated for its rock ſalt and brine pits. The ſtratum of ſalt lies about 40 yards deep; and ſome of the pits are hollowed into the form of a temple. The deſcent is through a dome, the roof ſupported by rows of pillars about two yards thick, and ſeveral in height; and when illuminated with a ſufficient number of candles, they make a moſt magnificent appearance. Above the ſalt is a bed of whitiſh clay (*Argilla cerulo-cinerea*), uſed in making the Liverpool earthen ware; and in the ſame place is alſo dug a good deal of the gypſum, or plaſter ſtone. The foſſil ſalt is generally yellow, and ſemipellucid, ſometimes debaſed with a dull greeniſh earth; and is often found, but in ſmall quantities, quite clear and colourleſs. The town is ſituated near the river Dane, and is tolerably handſome: it has a market on Fridays. It is 20 miles north-eaſt of Cheſter, and 173 north-weſt of London. W. Long. 2. 36. N. Lat. 53. 16.

NORTON, in Cheſhire, a good modern alms houſe, founded by P—y Brooke, Eſq; on the ſite of a priory of canons regular of St Auguſtine, founded by William, ſon of Nigellus, A. D. 1135, who did not live to complete his deſign; for Euſtace de Burgaville granted to Hugh de Catherine paſtures for 100 ſheep, in caſe he finiſhed the church in all reſpects conformable to the intent of the founders. It was granted afterwards to R. Brooke, Eſq.

NORTON'S sound, was diſcovered in Capt. Cook's laſt voyage, and was ſo named in honour of Sir Fletcher Norton (Lord Grantley), a near relation of Mr, afterwards Dr, King. It extends as far as N. Lat. 64° 55'. There is no good ſtation for ſhips, nor even a tolerable harbour in all the ſound. Mr King, on his landing here, diſcerned many ſpacious valleys, with rivers flowing through them, well wooded, and bounded with hills of a moderate height. One of the rivers towards the north-weſt ſeemed to be conſiderable; and he was inclined to ſuppoſe, from its direction, that it diſcharged itſelf into the ſea from the head of the bay. Some of his people, penetrating beyond this into the country, found the trees to be of a larger ſize the further they proceeded. E. Long. 197. 13. N. Lat. 64. 31.

NORWAY, a country of Europe (for the map ſee Denmark), lying between the 57th and 72d degrees of north latitude, and between the 5th and 31ſt degrees of longitude eaſt from London; extending in length about 1000 miles, in a direct line from Lindeſnaes, in the dioceſe of Chriſtianſand, to the North Cape, at the extremity of Finmark. Its breadth, from the frontiers of Sweden weſtward to Cape Statt, may amount to about 300 miles; but from thence the country becomes gradually narrower towards the north. On the ſouth it is bounded by the Schagen rock, or Categatt, the entrance into the Baltic; on the eaſt it is divided from Sweden by a long ridge of high mountains; and on the weſt and north it is waſhed by the northern ocean. In the ſouthern part of Norway, the country is craggy, abrupt, and mountainous, diverſified ſometimes with fertile and even delightful ſpots. In theſe reſpects it reſembles Switzerland: the proſpects and the meteorological phenomena ſeem to be very ſimilar. The range of the thermometer is of great extent; in the ſummer having riſen to 88°, and in the winter fallen to —40°: in general it is between 80° and —22°.

Reſpecting the population of Norway it is difficult to attain to certainty. An author of ſome note (Coxe) ſeems to think it amounts to 750,000; but he appears to have over-rated it conſiderably.

The Norwegian peaſants are free, well clothed, well lodged, [illegible] [illegible] frank, open, and undaunted. They are ſaid to [illegible] very conſiderable reſemblance to the peaſants of Switzerland. The ſoil is too thin for the plough: corn is therefore obtained from the neighbouring ſtates; and the chief employment of the peaſants of Norway is grazing. The following extract from Mr Coxe, being a deſcription of the ſcene near Chriſtiana, is not beſide our purpoſe, and may not perhaps be diſagreeable to our readers.

Coxe's Travels.

"As we approached Chriſtiana, the country was more wild and hilly, but ſtill very fertile and agreeable; and about two miles from the town we came to the top of a mountain, and burſt upon as fine a view as ever I beheld. From the point in which we ſtood in raptures, the grounds laid out in rich encloſures, gradually ſloped to the ſea; below us appeared Chriſtiana, ſituated at the extremity of an extenſive and fertile valley, forming a ſemicircular bend along the ſhore of a moſt beautiful bay, which, being encloſed by hills, uplands, and foreſts, had the appearance of a large lake. Behind, before, and around, the inland mountains of Norway roſe on mountains covered with dark foreſts of pines and fir, the inexhauſtible riches of the north. The moſt diſtant ſummits were caped with eternal ſnow. From the glow of the atmoſphere, the warmth of the weather, the variety of the productions, and the mild beauties of the adjacent ſcenery, I could ſcarcely believe that I was nearly in the 60th degree of northern latitude."

The coaſt of Norway, extending above 300 leagues, is ſtudded with a multitude of ſmall iſlands, affording habitation to fiſhermen and pilots, and paſture to a few cattle. They form an infinite number of narrow channels, and a natural barrier of rocks, which renders Norway inacceſſible to the naval power of its enemies. Attempts of this kind are the more dangerous, as the ſhore is generally bold, ſteep, and impending; ſo that cloſe to the rocks the depth of the ſea amounts to 100, 200, or 300 fathoms. The perils of the north ſea are moreover increaſed by ſudden ſtorms, ſunk rocks, violent currents, and dreadful whirlpools. The moſt remarkable vortex on this coaſt is called *Moſkoe-ſtrom*, from the ſmall iſland Moſkoe, belonging to the diſtrict of Lofoden in the province of Nordland. In time of flood, the ſtream runs up between Lofoden and Moſkoe with the moſt boiſterous rapidity; but in its ebb to the ſea, it roars like a thouſand cataracts, ſo as to be heard at the diſtance of many leagues. The ſurface exhibits different vortices; and if in one of theſe any ſhip or veſſel is abſorbed, it is whirled down to the bottom, and daſhed in pieces againſt the rocks. Theſe violent whirlpools continue without intervals, except for a quarter of an hour, at high and low water, in calm weather; for the boiling gradually returns as the flood or ebb advances. When its fury is heightened by a ſtorm, no veſſel ought to venture within a league of it. Whales have been frequently abſorbed within the vortex, and howled and bellowed hideouſly in their fruitleſs endeavours to diſengage themſelves. A bear, in attempting to ſwim from Lofoden to Moſkoe, was once hurried into this whirlpool, from whence he ſtruggled in vain for deliverance, roaring ſo loud as to be heard on ſhore; but notwithſtanding all his efforts, he was borne down and deſtroyed. Large trees being abſorbed by the current, are ſucked down, and riſe again all ſhattered into ſplinters. There are three vortices of the ſame kind near the iſlands of Ferroe.

Norway is divided into the four governments of Aggerhus, Bergen, Drontheim, and Wardhus, beſides that of Bahus, which is now ſubject to Sweden. The province of Aggerhus comprehends the ſouth-eaſt part of Norway, extending in length about 300 miles. Its chief towns are Chriſtiana, the ſee of a biſhop, ſuffragan to the metropolitan ſee of Drontheim, where the ſupreme court of juſtice is held, in preſence of the viceroy and the governor of the province; Aggerhus, about 15 miles to the ſouth-weſt of Chriſtiana; Frederickſhall or Frederickſtadt, in the ſiege of which Charles XII. of Sweden loſt his life: Saltzberg, Tonſberg, Alleen, Hammar, and Hollen.

The government of Bergen lies in the moſt ſoutherly and weſterly part of Norway, including the city of the ſame name, which is an epiſcopal ſee, and a place of conſiderable trade; and Staff-hanger, ſituated in the bay of Buckenfior, about 80 miles to the ſouthward of Bergen. The third province, called *Drontheim* or *Trontheim*, extends about 500 miles along the coaſt; and is but thinly peopled. The chief town Drontheim, ſeated on a little gulf at the mouth of the river Nider, is the only metropolitan ſee in Norway; and carries on a conſiderable trade in maſts, deals, tar, copper, and iron. Leetſtrand, Stronden, Scoerdale, Opdal, Romſdael, and Solendael, are likewiſe places of ſome traffic. The northern diviſion of Drontheim, called the *ſub-government of Salten*, comprehends the towns Melanger and Scheen. The province of Wardhus, extending to the North Cape, and including the iſlands, is divided into two parts; namely, Finmark and Norwegian Lapland. The chief town, which is very inconſiderable, ſtands upon an iſland called *Ward*, from whence the place and the government derive their name. The province of Bahus, though now yielded to the Swedes, is reckoned part of Norway, being a narrow tract of land, about 90 miles in length, lying on the coaſt of the Categate.

The great chain of Norway mountains, running from north to ſouth, called indifferently *Rudfield*, *Sudfield*, *Skarsfield*, and *Scoreberg*, is known in different parts by other appellations; ſuch as *Dofrefiell*, *Lamsfield*, *Sagnifield*, *Filefield*, *Halnefield*, *Hardangerfield*, *Joklefield*, *Byglefield*, *Hicklefield*, and *Hangfield*. The height and breadth of this extenſive chain likewiſe vary in different parts. To paſs the mountain Hardanger, a man muſt travel about 70 Engliſh miles, whereas Filefield may be about 50 over. This laſt riſes about two miles and a half in perpendicular height; but Dofrefield is counted the higheſt mountain of Norway, if not of Europe. The river Drivane winds along the ſide of it in a ſerpentine courſe, ſo as to be met nine times by thoſe who travel the winter road to the other ſide of the chain. The bridges are thrown over roaring cataracts, and but indifferently faſtened to the ſteep rocks on either ſide; ſo that the whole exhibits a very dreadful appearance, ſufficient to deter the traveller from hazarding ſuch a dangerous paſſage; for which reaſon, people generally chooſe the road over Filefield, which is much more tedious. This, however, is the poſt road uſed by the king's carriages. The way is diſtinguiſhed by poſts fixed at the diſtance of 200 paces from each other, that, in ſnowy or dark weather, the traveller may not be bewildered. For the convenience of reſting and refreſhing, there are two mountain ſtoves or houſes maintained on Filefield, as well as upon other mountains, at the expence of the public, and furniſhed with fire, light, and kitchen utenſils. Nothing can be more diſmal and dreary than thoſe mountains covered with [illegible] ſnow, where neither houſe, tree, nor living creature is to be ſeen, but here and there a ſolitary rein deer, and perchance a few wandering Laplanders.

In travelling from Sweden to Nordenfields, there is only one way of avoiding this chain of mountains; and that is, where it is interrupted by a long deep valley, extending from Romſdale to Guldbrandſdale. In the year 1612, a body of 1000 Scots, commanded by Sinclair, and ſent over as auxiliaries to the Swedes, were put to the ſword in this defile, by the peaſants of Guldbrand, who never give quarter.

Beſides this chain, there is a great number of detached mountains over all the country, that form valleys and ridges, inhabited by the peaſants. Some of theſe are of incredible height, and others exhibit very remarkable appearances. In ſailing up Joering Creek on the left hand, the ſight is aſtoniſhed with a group of mountains, reſembling the proſpect of a city, with old Gothic towers and edifices. In the pariſh of Oerſkoug is the high mountain Skopſhorn, the top of which repreſents the figure of a fortification, with regular walls and baſtions. In the diſtrict of Hilgeland appears a very high range of mountains, with ſeven pinnacles or creſts, known by the appellation of the *Seven Siſters*, diſcernible a great way off at ſea. To the ſouthward of this range, though in the ſame diſtrict, riſes the famous mountain *Torghatten*, ſo called becauſe the ſummit reſembles a man's head with a hat on, under which appears a ſingle eye, formed by an aperture through the mountain, 150 ells high, and 3000 ells in length. The ſun may be ſeen through this ſurpriſing cavity, which is paſſable by the foot of travellers. On the top of the mountain we find a reſervoir of water, as large as a moderate fiſh pond: in the lower part is a cavern, through which a line 400 fathoms in length, being let down, did not reach the bottom. At Herroe in Sundmoer is another cavern called *Dolſteen*, ſuppoſed to reach under the ſea to Scotland; which, however, is no more than an idle tradition. In the year 1750, two clergymen entered this ſubterranean cavity, and proceeded a conſiderable way, until they heard the ſea daſhing over their heads: the paſſage was as wide and high as an ordinary church, the ſides perpendicular, and the roof vaulted. They deſcended one flight of natural ſtairs; but arriving at another, they were afraid to penetrate farther: they had gone ſo far, however, that two candles were conſumed in their progreſs and return. A cavern of a very curious nature, ſerving as a conduit to a ſtream of water, penetrates through the ſides of the mountain Limur. In the diſtrict of Rake, in the neighbourhood of Frederickſhall, are three cavities in a rock; one of which is ſo deep, that a ſmall ſtone dropped down, does not reach the bottom in leſs than two minutes; and then the ſound it produces is pleaſant and melodious, not unlike the ſound of a bell.

The vaſt mountains and rugged rocks that deform the face of this country are productive of numberleſs inconveniences. They admit of little arable ground: they render the country in ſome parts impaſſable, and everywhere difficult to travellers: they afford ſhelter to wild beaſts, which come from their lurking holes, and make terrible havock among the flocks of cattle: they expoſe the ſheep and goats, as well as the peaſant, to daily accidents of falling over precipices: they occaſion ſudden torrents, and falls of ſnow, which deſcend with incredible impetuoſity, and often ſweep away the labours of the huſbandman; and they are ſubject to dreadful diſruptions, by which huge rocks are rent from their ſides, and, hurling down, overwhelm the plains below with inevitable ruin. The peaſants frequently build their houſes on the edge of a ſteep precipice, to which they muſt climb by ladders, at the hazard of their lives; and when a perſon dies, the corpſe muſt be let down with ropes, before it can be laid in the coffin. In winter the mail is often drawn up the ſides of ſteep mountains. Even in the king's road, travellers are expoſed to the frequent riſks of falling over thoſe dreadful rocks; for they are obliged to paſs over narrow pathways, without rails or riſing on the ſides, either ſhored up with rotten poſts, or ſuſpended by iron bolts faſtened in the mountains. In the narrow paſs of Naeroe is a remarkable way of this kind, which, above 600 years ago, the famous King Surre cauſed to be made for the paſſage of his cavalry; and even this would have been found impaſſable by any other horſes than thoſe of Norway, which are uſed to climb the rocks like goats. Another very difficult and dangerous road is that between Shogſtadt and Vang-in-Volders, along the ſide of a ſteep mountain, in ſome places ſo narrow, that if two travellers on horſeback ſhould meet in the night, they would find it impracticable either to paſs each other, or turn back. In ſuch a caſe their lives could not be ſaved, unleſs one of them ſhould alight, and throw his horſe headlong into the lake below, and then cling to the rock, until the other could paſs. When a ſheep or goat makes a falſe ſtep to the projection of a rock, from whence it can neither aſcend nor deſcend, the owner hazards his own life to preſerve that of the animal. He directs himſelf to be lowered down from the top of the mountain, ſitting on a croſs ſtick, tied to the end of a long rope; and when he arrives at the place where the creature ſtands, he faſtens it to the ſame cord, and it is drawn up with himſelf. Perhaps the other end of the rope is held by one perſon only; and there are ſome inſtances in which the aſſiſtant has been dragged down by the weight of his friend, ſo that both have periſhed. When either man or beaſt has had the misfortune to fall over very high precipices, they have not only been ſuffocated by the repercuſſion of the air, but their bodies have been always burſt before they reached the ground. Sometimes entire creſts of rocks, many fathoms in length and breadth, have fallen down at once, creating ſuch a violent agitation of the air, as ſeemed a prelude to the world's diſſolution. At Steenbroe in Laerdale, a ſtupendous maſs, larger than any caſtle in the univerſe, appears to have been ſevered and tumbled from the mountain in large, ſharp, and ragged fragments, through which the river roars with hideous bellowing. In the year 1731, a promontory on Sundmoer, called *Rammerſfield*, that hung over Nordal Creek, ſuddenly gave way, and plunged into the water; which ſwelled to ſuch a degree, that the church of Strand, though half a league on the other ſide of the bank, was overflowed: the creek, however, was not filled up; on the contrary the fiſhermen declare they find no difference in the depth, which is ſaid to exceed 900 fathoms.

The remarkable rivers of Norway are theſe: The Nied, iſſuing from Tydalen, on the borders of Sweden, runs weſtward into the lake Selboe; and afterwards, turning to the northward, paſſes by the city of Drontheim, to which it anciently gave the name of *Nidaros* and *Nidroſia*: Sule Ely, that deſcending from Sulefield, runs with a rapid courſe through Nordale into the ſea: Gulen, which riſes near Sſarsfield in the north; and running 20 leagues weſtward, through Aalen, Hlotaalen, Storen, and Melhuus, diſcharges itſelf into the ſea, about a league to the weſt of Drontheim. In the year 1344, this river buried itſelf under ground: from whence it again burſt forth with ſuch violence, that the earth and ſtones thrown up by the eruption filled the valley, and formed a dam; which, however, was ſoon broken and waſhed away by the force of the water. Divers churches, 48 farm houſes, with 250 perſons, were deſtroyed on this occaſion.—Otteroen, a large river, taking its riſe from the mountain Agde, runs about 30 leagues through Seeterdale and Eſie, and diſembogues itſelf into the cataract of Wiland. The river Syre riſes near the mountain Lang, and winds its courſe through the vale of Syre into the lake of Lunde in the dioceſe of Chriſtianſand; thence it continues its way to the ſea, into which it diſcharges itſelf through a narrow ſtrait formed by two rocks. This contraction augments its impetuoſity, ſo that it ſhoots like an arrow into the ſea, in which it produces a very great agitation. Nid and Sheen are two conſiderable rivers, iſſuing out of Tillemark. Their water-falls have been diverted, with infinite labour, by canals and paſſages cut through the rocks, for the convenience of floating down the timber. Tyrefiord or Dramme, is in the neighbourhood of Honifoſſe, joined by two rivers from Oedale and Hadeland, and diſembogues itſelf into the ſea near Bragneſs. Loven riſes in the higheſt part of Nummedal, and runs through Konſberg to the ſea near Laurwig. Glaamen is the largeſt river of Norway, diſtinguiſhed by the name of *Stor Elvin*, or the *great river*. It derives its origin from the mountain Dofre, from whence it winds all along the plains of Oeſterdale and Soloe; then joins the Vorme, another conſiderable river riſing out of Mioes and Guldbrandſdale. Theſe being joined, traverſe the lake Oeyeren; and thence iſſuing, run on to Sarp near Frederickſtadt.

Norway abounds with freſh water lakes; the principal of which are Ryſvand in Nordland, Snaaſen, Selboe, the Greater and Leſſer Mioes, Slirevand, Sperdille, Rand, Veſtn, Saren, Modum, Lund, Norſoe, Huidſoe, Fariſvand, and Oeyevand: all theſe are well ſtocked with fiſh, and navigable for large veſſels. Wars have been formerly carried on upon theſe inland ſeas; in ſome of which are ſmall floating iſlands, or parcels of earth, with trees on them, ſeparated from the main land, and probably preſerved in compact maſſes by the roots of trees, ſhrubs, and graſs, interwoven in the ſoil. In the year 1702, the family ſeat of Borge, near Frederickſtadt, being a noble edifice, with lofty towers and battlements, ſuddenly ſunk into an abyſs 100 fathoms deep, which was inſtantaneouſly filled by a piece of water 300 ells in length, and about half as broad. Fourteen perſons, with 200 head of cattle, periſhed in this cataſtrophe, which was occaſioned by the river Glaamen precipitating itſelf down a water-fall near Sarp, and undermining the foundation. Of all the water-falls in Norway this of Sarp is the moſt dangerous for its height and rapidity. The current drives 17 mills; and roars with ſuch violence, that the water, being daſhed and comminuted among the rocks, riſes in the form of mist, where a beautiful rainbow may be always ſeen when the ſun ſhines. In ancient times this cataract was made uſe of for the execution of traitors and other malefactors: they were thrown down alive, that they might be daſhed in pieces on the points of rocks, and die in a dreadful commotion, analogous to thoſe they had endeavoured to excite in the community.

Great part of Norway is covered with foreſts of wood, which conſtitute the principal article of commerce in this country. They chiefly conſiſt of fir and pine, for which great ſums are received from foreigners, who export an immenſe number of maſts, beams, planks, and boards. Beſides, an incredible quantity is conſumed at home in building houſes, ſhips, bridges, piles, moles, and fences; over and above the vaſt demand for charcoal to the founderies, and fuel for domeſtic uſes.—Nay, in ſome places, the trees are felled for no other purpoſe but to clear the ground and to be burned into aſhes for manure. A good quantity of timber is yearly exported to Scotland and Spain: but this is inconſiderable when compared to the vaſt exports from Drammen, Frederickſhall or Frederickſtadt, Chriſtiana, Skeen, Arendal, Chriſtianſand, Chriſtian's Bay, and Drontheim. The maſts and large beams are floated down the rivers, and the reſt is divided into boards at the ſaw mills. Theſe works ſupply a vaſt number of families with a comfortable ſubſiſtence.—A tenth part of all ſawed timber belongs to his Daniſh majeſty, and makes a conſiderable branch of his revenue. The foreſts in Norway are ſo vaſt and thick, that the people ſeem to think there can never be a ſcarcity of wood, eſpecially as the ſoil is peculiarly adapted for the production of timber: they therefore deſtroy it with a waſteful hand; inſomuch that more wood rots in Norway than is burned in the whole kingdom of Denmark. The beſt timber grows in the provinces of Saltan, Helleland, Romſdale, Guldbrandſdale, Oeſterdale, Soloe, Valders, Hallingdale, Sogniſiord, Tellemark, and the lordſhip of Nedene.

The climate of Norway is very different in different parts of the kingdom. At Bergen the winter is ſo moderate, that the ſeas are always open and practicable both to mariners and fiſhermen, except in creeks and bays, that reach far up into the country towards Filefield, when the keen north-eaſt wind blows from the land. On the eaſt ſide of Norway from the frontiers of Sweden to Fileſield, the cold generally ſets in about the middle of October with great ſeverity, and laſts till the middle of April; during which interval the waters are frozen to a very conſiderable thickneſs, and the face of the country is covered with ſnow. In the year 1719, 7500 Swedes, who intended to attack Drontheim, periſhed in the ſnow on the mountain of Ruden or Tydel, which ſeparates Jempteland in Sweden from the dioceſe of Drontheim. A company of 200 Norwegian ſledge-men under Major Emahus, found them all frozen to death on the ridge of the mountain, where they had been ſurpriſed by a ſtorm accompanied with ſnow, hail, and extreme cold. Some of theſe unhappy victims appeared ſitting, ſome lying, and others kneeling in a poſture of praying. They had cut in pieces their muſkets, and burned the little wood they afforded.—The Generals Labarre and Zoega loſt their lives; and of the whole corps, conſiſting originally of 10,000, no more than 2500 ſurvived this dreadful cataſtrophe.

The cold is ſtill more intenſe in that part of Norway called *Finmark*, ſituated in the frigid zone near the polar circle. But if the winter is generally cold, the ſummer is often exceſſively hot in Norway. The rays of the ſun are reverberated from the ſides of the mountains ſo as to render the weather cloſe and ſultry in the valleys; beſides, the ſun's abſence below the horizon is ſo ſhort, that the atmoſphere and mountains have not time to cool. The heat is ſo great, that vegetation is remarkably quick. Barley is ſown, grows, ripens, and is reaped, in the ſpace of ſix weeks or two months. The longeſt day at Bergen conſiſts of 19 hours; the ſun riſing at half an hour after two, and ſetting at half an hour after nine. * The ſhorteſt day does not exceed ſix hours; for the ſun riſes at nine in the morning, and ſets at three in the afternoon.—In the beginning of the year the daylight increaſes with remarkable celerity; and, at the approach of winter, decreaſes in the ſame proportion. In ſummer one may read and write at midnight by the light of the ſky. Chriſtian V. while he reſided at Drontheim, uſed to ſup at midnight without candles. In the diſtrict of Tromſen, at the extremity of Norway, the ſun is continually in view at midſummer. It is ſeen to circulate day and night round the north pole, contracting its orbit, and then gradually enlarging it, until at length it leaves the horizon. In the depth of winter, therefore, it is for ſome weeks inviſible; and all the light perceived at noon is a faint glimmering for about an hour and a half, proceeding from the reflexion of the ſun's rays from the higheſt mountains. But the inhabitants of theſe provinces are ſupplied with other lights that enable them to follow their employments in the open air. The ſky being generally ſerene, the moonſhine is remarkably bright, and, being reflected from the mountains, illuminates the valleys. They are alſo aſſiſted by the Aurora Borealis, which is very frequent in the northern parts of Europe.

The air of Norway is generally pure and ſalubrious. On the ſea coaſts, indeed, it is rendered moiſt by vapours and exhalations: but in the midland parts of the country, towards the mountains, the climate is ſo dry, that meal may be kept for many years without being worm eaten or damaged in the leaſt. The inhabitants have no idea of ſickneſs, except what is occaſioned by exceſſes. It is ſaid, that in the vale of Guldbrand the inhabitants live to ſuch extreme old age, that they become weary of life, and cauſe themſelves to be removed to a leſs ſalubrious climate, whereby they may have a chance of dying the ſooner. In conſumptions, however, the moiſt air on the ſea ſide is found to be moſt agreeable to the lungs in reſpiration. Norway, being a mountainous country interſected by creeks, abounding with lakes, rivers, and ſnow, muſt be ſubject to frequent rains; and from ſudden thaws the inhabitants are ſometimes expoſed to terrible diſaſters. Vaſt maſſes of ſnow falling from precipices overwhelm men, cattle, boats, houſes, nay even whole villages.—About two centuries ago, a whole pariſh was covered and deſtroyed by an immenſe maſs of ſnow; and ſeveral domeſtic utenſils, as ſciſſars, knives, and baſons, have been at different times brought to light by a rivulet that runs under the ſnow, which has been gradually hardened and increaſed by repeated froſts and annual acceſſions.

The winds that chiefly prevail on the weſtern coaſt are thoſe that blow from the ſouth; whereas, on the other ſide of Filefield, the winds that produce and continue the hard froſts are always northerly. In the ſummer, there is a kind of regular trade-wind on the coaſt of Bergen. In the forenoon the ſea begins to be cooled with a weſterly breeze, which continues till midnight. Then the land breeze begins from the eaſt, and blows till about ten in the morning. The coaſt is likewiſe ſubject to ſudden ſqualls and ſtorms. Hurricanes ſometimes riſe at ſea; and in theſe latitudes the phenomenon called a *water-ſpout* is not uncommon. One of theſe in the neighbourhood of Ferro is ſaid to have ſucked up with the water ſome laſts of herrings, which were afterwards dropped on Kolter, a mountain 1200 feet high.

The freſh water of Norway is not very light or pure; but on the contrary is generally turbid, and depoſites a ſediment of adventitious matter, being ſometimes impregnated with ochre and particles of iron.—Nevertheleſs it is agreeable to the taſte, and remarkably ſalubrious; as appears from the good health of the common people, who drink little or no other liquor.

The ſoil of Norway varies in different places according to the ſituation of rock or valley. The mountains here, as in every other country, are bare and barren; but the earth waſhed down from them by the rains enriches and fertilizes the valleys. In theſe the ſoil generally conſiſts of black mould, ſand, loam, chalk, and gravel, lying over one another in unequal ſtrata, and ſometimes in three or four ſucceſſions: the mould that lies uppermoſt is very fine and mellow, and fit to nouriſh all ſorts of vegetables. There is alſo clay found in different parts of this kingdom, of which the inhabitants begin to make earthen ware; but bricks and tiles are not uſed in building. The face of the country is in many places deformed by large ſwamps and marſhes, very dangerous to the traveller. Near Leeſſoe in the dioceſe of Chriſtianſand, a wooden cauſeway is extended near a mile over a moraſs; and if a horſe or any other animal ſhould make a falſe ſtep, he will ſink at once into the abyſs, never to riſe again.

In a cold country like Norway, roughened with rocks and mountains, interſperſed with bogs, and covered with foreſts, we cannot expect to find agriculture in perfection. The ploughed lands, in reſpect to mountains, woods, meadows, and waſtes, do not exceed the proportion of 1 to 80; ſo that the whole country does not produce corn to maintain above half the number of its inhabitants. The peaſants are diſcouraged from the practice of huſbandry by the frequency of accidents that ſeem peculiar to the climate. Even in the fruitful provinces of Guldbrandſdale, Oeſterdale, and Soloer, as well as in other places, when the corn appears in the moſt flouriſhing condition the whole hope of the harveſt is ſometimes deſtroyed in one night by a ſudden froſt that nips the blade and extinguiſhes the vegetation. The kingdom is moreover viſited by ſome unfavourable years, in which the ſun ſeems to have loſt his genial power; the vegetables are ſtunted; the trees bud and bloom, yet bear no fruit; and the grain, though it riſes, will yet produce nothing but empty ears and ſtraw. This calamity, however, rarely occurs; and in general the cultivated parts of Norway yield plentiful crops of excellent rye, barley, and oats. The moſt fruitful provinces are Nordland, Inderbarre, and Numedale, in the dioceſe of Drontheim; Sognifiord and Vaas, in that of Bergen; Jedderen, Ryefylſk, Raabygdelag, and the lordſhip of Nedenes, in the dioceſe of Chriſtianſand; Hedemark in the dioceſe of Aggerhus; Hadeland, Toten, Romerige, Ringerige, and Guldbrandſdale: theſe territories not only produce grain enough for their own conſumption, but likewiſe ſupport their neighbours, and even ſupply part of Sweden.—Peaſe are likewiſe propagated in this country, together with wheat, buck-wheat, hops, hemp, and flax, but not to any conſiderable advantage. The meadows are well ſtored with paſturage for ſheep and cattle, and the fields are productive of thoſe vegetables which are common in other northern countries. Within theſe 50 years the people of Norway have beſtowed ſome attention on the culture of gardens, which in former times was ſo neglected, that the cities and towns were ſupplied with leeks, cabbage, and roots, from England and Holland. At preſent, however, the Norwegians raiſe their own culinary and garden roots and vegetables, which thrive there as well as in any other country. The ſcurvy being a diſeaſe that prevails along the ſea coaſt, Nature has ſcattered upon it a variety of herbs efficacious in the cure of that diſtemper; ſuch as angelica, roſe-wort, gentian, creſſes, trefoil, ſorrel, ſcurvy-graſs, and a plant called *erich's graſs*, that grows in great plenty on the iſlands of Northland: from whence the people of the continent fetch away boat loads of it, to be preſerved in barrels as a ſuccedaneum for cabbage. There are alſo a few noxious vegetables little known in any country but Norway. In Guldbrandſdale is a ſpecies of graſs called *ſelſnape*; the root of which is ſo poiſonous, that any beaſt which eats of it dies immediately, the belly burſting; nay, the carnivorous fowls that prey upon the carcaſs of the beaſt meet with the ſame fate: children have been more than once poiſoned by this root, which nevertheleſs is ſometimes uſed externally as an amulet for arthritic diſorders. Another vegetable pernicious to the cattle is the *Gramen oſſifragum Norwegienſe*, which is ſaid to mollify the bones of the cattle which feed upon it. Among the noxious plants of Norway we may alſo reckon the igle-graſs, fatal to ſheep and goats; the tour-graſs, which affects horſes and cows with a ſort of lethargy; and the plant torboe, or hiſte-ſpring, which produces nearly the ſame effect on horſes, but is not at all prejudical to cows, ſheep, or any ruminating animals. The herb turte, not unlike angelica, operates nearly in the ſame manner; yet the bears are ſaid to feed upon it with peculiar reliſh; and when their hair begins to fall off by feeding upon this plant, they cure themſelves by eating the fleſh of animals.

The common fruit trees thrive tolerably well in Norway, the inhabitants of which have plenty of cherries, apples, and pears. Some kinds of plums attain maturity; which is ſeldom the caſe with grapes, apricots, and peaches. But even the apples and pears that ripen here are ſummer fruit; that which grows till the winter ſeldom comes to perfection. Great variety of agreeable berries are produced in different parts of this kingdom; ſuch as the hagebar, a kind of ſloes; an infuſion of which in wine makes a pleaſant cooling liquor; juniper berries, corinths red and white, ſoelbar or ſun berries, raſpberries, gooſeberries, blackberries, ſtrawberries, &c. with many other ſpecies that ſeem to be natives of Norway and Sweden. Among thoſe are the tranæbar, the produce of the myrtillus repens, red and auſtere, found in the ſpring in perfection under the ſnow, and much reliſhed by the reindeer; crakebeer, reſembling bilberries, deemed a powerful antiſcorbutic; agerbeer, larger and blacker than bilberries, of a pleaſant acid, ripened by cold, and uſed as cherries for an infuſion in wine; and finally tyltebeer, a red pleaſant berry growing on a ſhort ſtem, with leaves like thoſe of box, they are plucked off by handfuls, and ſent to Denmark to be preſerved for the table, where they are eaten by way of deſſert.

Of the trees that grow wild in Norway, the principal are the fir and the pine. The firſt yield an annual revenue of 1,000,000 of rixdollars, if we include the advantages reſulting from the ſaw mills and the maſts; one of which laſt has been known to ſell for 200 rixdollars. The red fir tree, which grows on the mountains, is ſo rich in turpentine as to be almoſt incorruptible. Some of the houſes belonging to the Norway peaſants, built of this timber, are ſuppoſed to be above 400 years ſtanding. In Guldbrandſdale the houſe is ſtill to be ſeen ſtanding in which King Olaf lodged five nights, above 700 years ago, when he travelled round the kingdom to convert the people to the Chriſtian faith. Even 100 years after the trunk of the fir tree has been cut down, the peaſants burn the roots for tar, which is a very profitable commodity. In the fens, the reſin of the fir tree is by nature transformed into a ſubſtance which may be called *Norway frankincenſe*. The buds or pine apples of this tree, boiled in ſtale beer, make an excellent medicine for the ſcurvy; leſs unpleaſant to the taſte, though as efficacious, as tar-water. The pine tree is more tall and beautiful than the fir, though inferior to it in ſtrength and quality: for which reaſon the planks of it are ſold at an inferior price, and the peaſants waſte it without remorſe. Norway likewiſe produces ſome foreſts of oak, which is found to be excellent for ſhip-building. Here alſo grow plenty of elm trees; the bark of which, being powdered, is boiled up with other food to fatten hogs, and even mixed by the poor among their meal: alſo the aſh, from which the peaſants diſtil a balſam uſed in certain diſorders, and which is uſed both externally and internally. Many other trees flouriſh in this country, an enumeration of which would prove too tedious. Hazels grow here in ſuch abundance, that 100 tons of the nuts are annually exported from Bergen alone.

A great diverſity of ſtones is found in Norway, ſome of which are of a ſurpriſing figure. Several mountains conſiſt chiefly of a brown pebble, which decays with age; nay, it ſometimes diſſolves, and drops into the ſea, and the cement being thus looſened, a terrible diſruption enſues. In ſome places the gray and black pebbles are intermixed with iron, copper, lead, ſilver, and gold. The ground [illegible] certain diſtricts is covered with the fragments of [illegible] that have been precipitated from the ſummits of mountains, and broken by their fall into innumerable ſhivers. Between 20 and 30 years ago, in the neighbourhood of Bergen, a man was ſuddenly overwhelmed with ſuch a maſs, which formed a kind of vault around him. In this dreadful tomb he remained alive for ſeveral weeks. By his loud cries the place of his confinement was diſcovered: but it was found impoſſible to remove the huge ſtones by which he was encloſed. All that his friends could do for him was, to lower down meat and drink through ſome crevices; but at length the ſtones fell in, and cruſhed him to death.

In Norway are inexhauſtible quarries of excellent marble, black, white, blue, gray, and variegated; together with ſome detached pieces of alabaſter, ſeveral kinds of ſpar, chalk-ſtone, cement-ſtone, ſand-ſtone, mill-ſtone, baking-ſtone, ſlate, talc, magnets; and ſwine-ſtone, a production natural to Norway and Sweden, of a brown colour, fetid ſmell, in texture reſembling cryſtal, and deriving its name from a ſuppoſed efficacy in curing a diſtemper incident to ſwine. Here alſo is found the amianthus or ſtone-flax, of which incombuſtible cloth may be made. Norway, however, affords no flints, but plenty of pyrites or quartz, beautiful cryſtals, granites, amethyſts, agate, thunder-ſtones, and eagle-ſtones. Gold has formerly been found in a ſmall quantity in the dioceſe of Chriſtianſand, and coined into ducats. There is at preſent a very conſiderable ſilver mine wrought at Kongſberg on the account and at the riſk of his Daniſh majeſty: the ore is ſurpriſingly rich, but interrupted in ſuch a manner, that the vein is often loſt. Many maſſes of pure ſilver have been found; and, among the reſt, one piece weighing 560 pounds, preſerved in the royal muſeum at Copenhagen. Such is the richneſs of theſe mines, that the annual produce amounts in value to a ton and a half in gold. About 5000 people are daily employed, and earn their ſubſiſtence, in thoſe ſtupendous works (A). Other ſilver mines are proſecuted at Jarlſberg, but not to the ſame advantage; and here the ore is mixed with lead and copper. In many parts of this country copper mines have been diſcovered; but the principal, and perhaps the richeſt in all Europe, is at Roraas, about 100 Engliſh miles from Drontheim. This work yields annually about 1100 ſhip pounds of pure copper: the founderies belonging to it conſume yearly about 14,000 laſts of coal, and 500 fathoms of wood. The next in importance is the copper work at Lykken, about 20 miles from Drontheim. A third mine is carried on at Indſet or Quickne, at the diſtance of 30 miles from the ſame place; and here they precipitate the copper from its menſtruum, by means of iron. There is a fourth copper work at Silboe, about 30 miles diſtant from Drontheim, though the leaſt conſiderable of the four. Other copper mines of leſs note are worked in different parts of the kingdom. Iron is ſtill in greater plenty, and was the firſt metal wrought in this country. Many hundred thouſand quintals are annually exported, chiefly in bars, and part of it in ſtoves, pots, kettles, and cannon: the national profit ariſing from this metal is eſtimated at 300,000 rixdollars. There is a ſpecies called *moor-iron*, found in large lumps among the moraſſes: of this the peaſants make their own domeſtic tools and utenſils, ſuch as knives, ſcythes, and axes. The lead found mixed in the ſilver ore is an article of ſmall importance in Norway; yet ſome mines of this metal have been lately opened in the diſtrict of Soloer by the proprietors of the copper work at Oudal. A vitriol work has been begun near Kongſberg: the mines yield great plenty of ſulphur; which, however, the Norwegians will not take the trouble to melt and depurate, becauſe immenſe quantities are found at a cheaper rate in the iſland of Iceland. Alum is found between the ſlate flakes near Chriſtiana in ſuch plenty, that works have been ſet up for refining this mineral, though they have not yet brought it to any degree of tranſparency. His Daniſh majeſty has eſtabliſhed ſalt works in the peninſula of Valoe, about ſix Engliſh miles from Tonſberg, where this mineral is extracted in large quantities from the ſea water.

Beſides the animals common to other countries, Norway is ſaid to contain many of the uncommon and dubious kind; ſuch as the kraken, mermaid, ſea ſerpent, &c. See theſe articles.

Many Daniſh, Engliſh, Scotch, Dutch, and German families have now ſettled in Norway; and indeed form no inconſiderble part of the trading people: but the original inhabitants are the deſcendants of thoſe ferocious Normanni, who haraſſed almoſt all the coaſts of Europe with piratical armaments in the 8th, 9th, and 10th centuries.

"Our firſt certain knowledge of the inhabitants of this country (ſays Pennant †) was from the deſolation they brought on the ſouthern nations by their piratical invaſions. Their country had before that period the name of *Nortmannaland*, and the inhabitants

† *Arct. Zool.*

(A) Mr Coxe tells us, that he viſited thoſe mines. They formerly, he ſays, produced annually 70,000l. but at preſent yield little more than 50,000l. The expences generally exceed the profits; and government gains only by the number of miners employed. The mines of cobalt, and the preparation of Pruſſian blue, are much more productive. The latter goes through 270 hands, and the number of men employed are 356. It is ſuppoſed, that, at this period (1793), it may produce to government a profit of 16,000l. a-year.

tants *Normans*; a title which included other adjacent people. Great Britain and Ireland were ravaged by them in 845; and they continued their invaſion till they effected the conqueſt of England, under their leader Canute the Great. They went up the Seine as far as Paris, burnt the town, and forced its weak monarch to purchaſe their abſence at the price of fourteen thouſand marks. They plundered Spain, and at length carried their excurſions through the Mediterranean to Italy, and even into Sicily. They uſed narrow veſſels, like their anceſtors the Sitones; and, beſides oars, added the improvement of two ſails; and victualled them with ſalted proviſions, biſcuit, cheeſe, and beer. Their ſhips were at firſt ſmall; but in after times they were large enough to hold 100 or 120 men. But the multitude of veſſels was amazing. The fleet of Harold Blaatand conſiſted of 700. A hundred thouſand of theſe ſavages have at once ſailed from Scandinavia, ſo juſtly ſtyled *Officina gentium, aut certè velut vagina nationum.* Probably neceſſity, more than ambition, cauſed them to diſcharge their country of its exuberant numbers. Multitudes were deſtroyed; but multitudes remained, and peopled more favourable climates.

"Their king, Olaus, was a convert to Chriſtianity in 994; Bernard an Engliſhman had the honour of baptizing him, when Olaus happened to touch at one of the Scilly iſlands. He plundered with great ſpirit during ſeveral years; and in 1006 received the crown of martyrdom from his pagan ſubjects. But religious zeal firſt gave the reſt of Europe a knowledge of their country and the ſweets of its commerce. The Hanſe towns poured in their miſſionaries, and reaped a temporal harveſt. By the year 1204, the merchants obtained from the wiſe prince Suer every encouragement to commerce; and by that means introduced wealth and civilization into his barren kingdom. England by every method cheriſhed the advantages reſulting from an intercourſe with Norway, and Bergen was the emporium. Henry III. in 1217, entered into a league with its monarch Haquin; by which both princes ſtipulated for free acceſs for their ſubjects into their reſpective kingdoms, free trade, and ſecurity to their perſons. In 1269, Henry entered into another treaty with Magnus; in which it was agreed, that no goods ſhould be exported from either kingdom except they had been paid for; and there is, beſides a humane proviſion on both ſides, for the ſecurity of the perſons and effects of the ſubjects who ſhould ſuffer ſhipwreck on their ſeveral coaſts."

The inhabitants now ſpeak the ſame language that is uſed in Denmark, though their original tongue is the dialect now ſpoken in Iceland. They profeſs the Lutheran religion, under an archbiſhop eſtabliſhed at Drontheim, with four ſuffragans; namely, of Bergen, Staffanger, Hammer, and Chriſtiana. By the union of Calmar, the two kingdoms of Norway and Denmark were united under one monarch; and then the people of both nations enjoyed conſiderable privileges: but the Daniſh government ſoon became abſolute; and Norway was ruled deſpotically by a viceroy, who reſided in the capital, and preſided in the ſupreme court, to which appeals were made from the ſubordinate courts of judicature. A great change has, however, taken place ſince the preſent amiable and accompliſhed prince of Denmark had part of the government; and more may be expected from his virtue and aſſiduity when the power ſhall come wholly into his own hands.

The Norwegians are generally well formed, tall, ſturdy, and robuſt, brave, hardy, honeſt, hoſpitable, and ingenious; yet ſavage, raſh, quarrelſome, and litigious. The ſame character will nearly ſuit the inhabitants of every mountainous country in the northern climates. Their women are well ſhaped, tall, comely, remarkably fair, and obliging. The nobility of Norway have been chiefly removed by the kings of Denmark, in order [illegible] prevent faction and oppoſition to the court; or are [illegible] degenerated into the rank of peaſants: ſome [illegible], however, have been lately raiſed to that dig[illegible] Every freeholder in Norway enjoys the right of primogeniture and power of redemption; and it is very uſual to ſee a peaſant inhabiting the ſame houſe which has been poſſeſſed 400 years by his anceſtors. The *odels-gads*, or freehold, cannot be alienated by ſale or otherwiſe from the right heir, called *odels-mand*: if he is not able to redeem the eſtate, he declares his incapacity every 10th year at the ſeſſions; and if he, or his heirs to the third generation, ſhould acquire wealth enough for that purpoſe, the poſſeſſor *pro tempore* muſt reſign his poſſeſſion.

The mountaineers acquire ſurpriſing ſtrength and dexterity by hard living, cold, laborious exerciſe, climbing rocks, ſkating on the ſnow, and handling arms, which they carry from their youth to defend themſelves againſt the wild beaſts of the foreſt. Thoſe who dwell in the maritime parts of Norway exerciſe the employments of fiſhing and navigation, and become very expert mariners.

The peaſants of Norway never employ any handicraftſmen for neceſſaries to themſelves and families: they are their own hatters, ſhoemakers, taylors, tanners, weavers, carpenters, ſmiths, and joiners: they are even expert at ſhip-building; and ſome of them make excellent violins. But their general turn is for carving in wood, which they execute in a ſurpriſing manner with a common knife of their own forging. They are taught in their youth to wreſtle, ride, ſwim, ſkate, climb, ſhoot, and forge iron. Their amuſements conſiſt in making verſes, blowing the horn, or playing upon a kind of guitar, and the violin: this laſt kind of muſic they perform even at funerals. The Norwegians have evinced their valour and fidelity in a thouſand different inſtances. The country was always diſtracted by inteſtine quarrels, which raged from generation to generation. Even the farmers ſtand upon their punctilio, and challenge one another to ſingle combat with their knives. On ſuch occaſions they hook themſelves together by their belts, and fight until one of them is killed or mortally wounded. At weddings and public feaſts they drink to intoxication, quarrel, fight, and murder generally enſues. The very common people are likewiſe paſſionate, ambitious of glory and independence, and vain of their pedigree. The nobility and merchants of Norway fare ſumptuouſly; but the peaſant lives with the utmoſt temperance and frugality, except at feſtivals: his common bread is made of oatmeal, rolled into broad thin cakes, like thoſe uſed in Scotland. In time of ſcarcity, they boil, dry, and grind the bark of the fir tree into a kind of flour which they mix with oat meal; the bark of the elm tree is uſed in the ſame manner. In thoſe parts where a fiſhery is carried on, they knead the roes of cod with their oat meal. Of theſe laſt, mixed with barley meal, they make haſty pudding and ſoup, enriched with a pickled herring or ſalted mackarel. Freſh fiſh they have in plenty on the ſea coaſt. They hunt and eat grouſe, partridge, hare, red deer, and rein-deer. They kill cows, ſheep, and goats, for their winter ſtock: theſe they pickle, or ſmoke, or dry for uſe. They make cheeſe of their milk, and a liquor called *ſyre* of their ſour whey: [illegible] they commonly drink mixed with water; but th[illegible]ide a ſtore of ſtrong ale for Chriſtmas, weddings, chriſtenings, and other entertainments. From their temperance and exercife, joined to the purity and elaſticity of their air, they enjoy good health, and often attain to a ſurpriſing degree of longevity. Nothing is more common than to ſee a hearty Norwegian turned of 100. In the year 1733, four couples danced before his Daniſh majeſty at Frederickſhall: their ages, when joined, exceeded 800 years. Nevertheleſs, the Norwegians are ſubject to various diſeaſes; ſuch as the ſcab, the leproſy, the ſcurvy, the catarrh, the rheumatiſm, gout, and epilepſy. The dreſs of the Norway peaſants conſiſts of a wide looſe jacket made of coarſe cloth, with waiſtcoat and breeches of the ſame. Their heads are covered with flapped hats, or caps ornamented with ribbons. They wear ſhoes without outer ſoles, and in the winter leathern buſkins. They have likewiſe ſnow ſhoes and long ſkates, with which they travel at a great pace, either on the land or ice. There is a corps of ſoldiers thus accoutred, who can outmarch the ſwifteſt horſes. The Norwegian peaſant never wears a neckcloth, except on extraordinary occaſions: he opens his neck and breaſt to the weather, and lets the ſnow beat into his boſom. His body is girt round with a broad leathern belt, adorned with braſs plates, from which depends a braſs chain that ſuſtains a large knife, gimlet, and other tackle. The women are dreſſed in cloſe laced jackets, having leathern girdles decorated with ornaments of ſilver. They likewiſe wear ſilver chains round their necks, to the ends of which are fixed gilt medals. Their caps and handkerchiefs are almoſt covered with ſmall plates of ſilver, braſs, and tin, large rings, and buttons. A maiden bride appears with her hair plaited, and, together with her clothes, hung full of ſuch jingling trinkets.

The churches, public edifices, and many private houſes in Norway, are built of ſtone: but the people in general live in wooden houſes, made of the trunks of fir and pine tree laid upon each other, and joined by mortiſes at the corners. Theſe are counted more dry, warm, and healthy, than ſtone or brick buildings. In the whole dioceſe of Bergen, one hardly ſees a farm houſe with a chimney or window: they are generally lighted by a ſquare hole in the top of the houſe, which lets in the light, and lets out the ſmoke. In ſummer this hole is left quite open: in the winter, it is covered with what they call a *ſiau;* that is the membrane of ſome animal, ſtretched upon a wooden frame that fits the hole, and tranſmits the rays of light. It is fixed or removed with a long pole occaſionally. Every perſon that enters the houſe, upon buſineſs or [illegible], takes hold of this pole, according to an[illegible] cuſtom. The ceiling is about eight feet high in the middle; and, being arched like a cupola, the ſmoke of the fire underneath rolls about, until it finds a vent at the hole, which is called *liur*. Under this opening ſtands a thick table with benches, and a high ſeat at the upper end for the maſter of the family: he has likewiſe a ſmall cupboard for his own uſe, in which he locks up his moſt valuable effects. The boards of the roof are coated with the bark of the birch trees, which is counted incorruptible: this again is covered with turf, which yields a good crop of graſs for goats and ſheep, and is often mowed as hay by the farmer.

The Norwegians carry on a conſiderable trade with foreign nations. The duty on the produce of their own country exported, amounts annually to 100,000 rixdollars. Theſe commodities are, copper wrought and unwrought; iron caſt into cannon, ſtoves, and pots, or forged into bars; lead, in ſmall quantity; maſts, timber, deal boards, planks, marble, millſtones, herring, cod, ling, ſalmon, lobſters, flounders, cow hides, goat ſkins, ſeal ſkins, the furs of bears, wolves, foxes, beavers, ermines, martens, &c. down, feathers, butter, tallow, train oil, tar, juniper and other ſorts of berries, and nuts; ſalt, alum, glaſs, vitriol, and pot aſhes. All other commodities and articles of luxury the Norwegians import from different nations. The nature of the ground does not admit of much improvement in agriculture: nevertheleſs, the farmers are not deficient in induſtry and ſkill to drain marſhes, and render the ground arable and fit for paſture. Many are employed in grazing and breeding cattle; but a much greater number is engaged in felling wood, floating timber, burning charcoal, and extracting tar from the roots of the trees which have been cut down in the ſilver, copper, and iron mines; in the navigation and fiſhery. A conſiderable number of people earn a comfortable livelihood by hunting, ſhooting, and bird catching. Every individual is at liberty to purſue the game, eſpecially in the mountains and commons: therefore every peaſant is expert in the uſe of fire arms; and there are excellent markſmen among the mountains, who make uſe of the bow to kill thoſe animals, whoſe ſkins, being valuable, would be damaged by the ſhot of fire arms.

Norway can produce above 14,000 excellent ſeamen. The army of this country amounts to 30,000 effective men; and the annual revenue exceeds 800,000 rixdollars.

NORWAY Rat, in zoology. See MUS.

NORWICH, the capital of the county of Norfolk in England, ſituated in E. Long. 1. 26. N. Lat. 52. 40. It is ſuppoſed to have had its name, which ſignifies "a caſtle to the north," from its ſituation in reſpect of Caſtor, the ancient Venta Icenorum, three or four miles to the ſouth of it, out of whoſe ruins it ſeems to have riſen. In its infancy, in the reign of Etheldred, it was plundered and burnt by Sueno the Dane, when he invaded England with a great army. Afterwards it recovered; and in the reign of Edward warded by the Romans for the important ſervices he had done them. As for Syphax, after the loſs of his dominions, he was kept in confinement for ſome time at Alba; from whence being removed in order to grace Scipio's triumph, he died at Tibur in his way to Rome. Zonaras adds, that his corpſe was decently interred; that all the Numidian priſoners were releaſed; and that Vermina, by the aſſiſtance of the Romans, took peaceable poſſeſſion of his father's throne. However, part of the Maſſæſylian kingdom had been before annexed to Maſiniſſa's dominions, in order to reward that prince for his ſingular fidelity and cloſe [illegible] to the Romans.

This ſeems to be countenanced by the [illegible] of Livy, who gives us ſufficiently to underſtand [illegible] phax's family, for a conſiderable time after the concluſion of the ſecond Punic war, reigned in one part of Numidia. For he intimates, that Archobarzanes, Syphax's grandſon, and probably Vermina's ſon, hovered with a powerful army of Numidians upon the Carthaginian frontiers a few years before the beginning of the third Punic war. This he ſeems to have done, either in order to cover them, or to enable the Carthaginians to make an irruption into Maſiniſſa's territories. Cato, however, pretended that theſe forces, in conjunction with thoſe of Carthage, had a deſign to invade the Roman dominions, which he urged as a reaſon to induce the conſcript fathers to deſtroy the African republic.

Nothing is further requiſite, in order to complete the hiſtory of this famous prince, than to exhibit to our readers view ſome point of his conduct towards the decline, and at the cloſe, of life; the wiſe diſpoſitions made after his death by Æmilianus, in order to the regulation of his domeſtic affairs; and ſome particulars relating to his character, genius, and habit of body, drawn from the moſt celebrated Greek and Roman authors.

By drawing a line of circumvallation around the Carthaginian army under Aſdrubal, poſted upon an eminence, Maſiniſſa cut off all manner of ſupplies from them; which introduced both the plague and famine into their camp. As the body of Numidian troops employed in this blockade was not near ſo numerous as the Carthaginian forces, it is evident, that the line here mentioned muſt have been extremely ſtrong, and conſequently the effect of great labour and art. The Carthaginians, finding themſelves reduced to the laſt extremity, concluded a peace upon the following terms, which Maſiniſſa dictated to them: 1. That they ſhould deliver up all deſerters. 2. That they ſhould recal their exiles, who had taken refuge in his dominions. 3. That they ſhould pay him 5000 talents of ſilver within the ſpace of 50 years. 4. That their ſoldiers ſhould paſs under the jugum, each of them carrying off only a ſingle garment. As Maſiniſſa himſelf, though between 80 and 90 years of age, conducted the whole enterpriſe, he muſt have been extremely well verſed in fortification, and other branches of the military art. His underſtanding likewiſe he muſt have retained to the laſt. This happened a ſhort time before the beginning of the third Punic war. See CARTHAGE.

Soon after, the conſuls landed an army in Africa, in order to lay ſiege to Carthage, without imparting to Maſiniſſa their deſign. This not a little chagrined him, as it was contrary to the former practice of the Romans; who in the preceding war had communicated their intentions to him, and conſulted him on all occaſions. When, therefore, the conſuls applied to him for a body of his troops to act in concert with their forces, he made anſwer, "That they ſhould have a reinforcement from him when they ſtood in need of it." It could not but be provoking to him to conſider, that after he had extremely weakened the Carthaginians, and even brought them to the brink of ruin, his pretended imperious friends ſhould come to reap the fruits of his victory, without giving him the leaſt intelligence of it.

5
Maſiniſſa diſpleaſed with the Romans;

However, his mind ſoon returned to its natural bias, which was in favour of the Romans. Finding his end approaching, he ſent to Æmilianus, then a tribune in the Roman army, to deſire a viſit from him. What he propoſed by this viſit, was to inveſt him with full powers to diſpoſe of his kingdom and eſtate as he ſhould think proper, for the benefit of his children. The high idea he had entertained of that young hero's abilities and integrity, together with his gratitude and affection for the family into which he was adopted, induced him to take this ſtep. But, believing that death would not permit him to have a perſonal conference with Æmilianus upon this ſubject, he informed his wife and children in his laſt moments, that he had empowered him to diſpoſe in an abſolute manner of all his poſſeſſions, and divide his kingdom amongſt his ſons. To which he ſubjoined, "I require, that whatever Æmilianus may decree, ſhall be executed as punctually as if I myſelf had appointed it by my will." Having uttered theſe words, he expired, at about 90 years of age.

6
but leaves every thing to the diſpoſal of Æmilianus

This prince, during his youth, had met with ſtrange reverſes of fortune. However, ſays Appian, being ſupported by the Divine protection, he enjoyed an uninterrupted courſe of proſperity for a long ſeries of years. His kingdom extended from Mauritania to the weſtern confines of Cyrenaica; from whence it appears, that he was one of the moſt powerful princes of Africa. Many of the inhabitants of this vaſt tract he civilized in a wonderful manner, teaching them to cultivate their ſoil, and to reap thoſe natural advantages which the fertility of ſome parts of their country offered them. He was of a more robuſt habit of body than any of his cotemporaries, being bleſſed with the greateſt health and vigour; which was doubtleſs owing to his extreme temperance, and the toils he inceſſantly ſuſtained. We are informed by Polybius, that ſometimes he ſtood upon the ſame ſpot of ground from morning till evening, without the leaſt motion, and at others continued as long in a ſitting poſture. He would remain on horſeback for ſeveral days and nights together, without being ſenſible of the leaſt fatigue. Nothing can better evince the ſtrength of his conſtitution, than his youngeſt ſon, named *Stembal*, *Sthemba*, or *Stemlanus*, who was but four years old at his deceaſe. Though 90 years of age, he performed all the exerciſes uſed by young men, and always rode without a ſaddle. Pliny tells us, that he reigned above 60 years. He was an able commander, and much facilitated the reduction of Carthage. Plutarch from Polybius obſerves, that the day after a great victory won over the Carthaginians, Maſiniſſa was ſeen ſitting at door of his tent, eating a piece of brown bread. Suidas relates, that to the laſt he could mount his horſe without any aſſiſtance. According to Appian he left a numerous well diſciplined army, and an immenſe quantity of wealth, behind him.

Maſiniſſa, before his death, gave his ring to his eldeſt ſon Micipſa; but left the diſtribution of all his other effects and poſſeſſions amongſt his children entirely to Æmilianus. Of 54 ſons that ſurvived him, only three were legitimate, to wit, Micipſa, Guluſſa, and Maſtanabal. Æmilianus, arriving [illegible] after he had expired, divided his kingdom, or rather the government of it, among theſe three, though to the others he gave conſiderable poſſeſſions. To Micipſa, who was a prince of a pacific diſpoſition, and the eldeſt ſon, he aſſigned Cirta, [illegible] metropolis, for the place of his reſidence, in excluſion of the others. Guluſſa, the next to him, being a prince of a military genius, had the command of the army, and the tranſacting of all affairs relating to peace [illegible]r committed to his care. And Manaſtabal, the youngeſt, had the adminiſtration of juſtice, an employment ſuitable to his education, allotted him. They enjoyed in common the immenſe treaſures Maſiniſſa had amaſſed, and were all of them dignified by [illegible]milianus with the royal title. After he had made theſe wiſe diſ[illegible], that young nobleman departed from Cirta, taking with him a body of Numidian troops, under the conduct of Guluſſa, to reinforce the Roman army that was then acting againſt the Carthaginians.

Maſtanabal and Guluſſa died ſoon after their father, as appears from the expreſs teſtimony of Salluſt. We find nothing more remarkable of theſe princes, beſides what has been already related, than that the latter continued to aſſiſt the Romans in the third Punic war, and that the former was pretty well verſed in the Greek language. Micipſa therefore became ſole poſſeſſor of the kingdom of Numidia. In his reign, and under the conſulate of M. Plautius Hypſæus and M. Fulvius Flaccus, according to Oroſius, a great part of Africa was covered with locuſts, which deſtroyed all the produce of the earth, and even devoured dry wood. But at laſt they were all carried by the wind into the African ſea, out of which being thrown in vaſt heaps upon the ſhore, a plague enſued, which ſwept away an infinite number of animals of all kinds. In Numidia only 800,000 men periſhed, and in Africa Propria 200,000; amongſt the reſt, 30,000 Roman ſoldiers quartered in and about Utica for the defence of the latter province. At Utica, in particular, the mortality raged to ſuch a degree, that 1500 dead bod[illegible] were carried out of one gate in a day. Micipſa had two ſons, Adherbal and Hiempſal, whom he educated in his palace, together with his nephew Jugurtha. That young prince was the ſon of Maſtanabal; but his mother having been only a concubine, Maſiniſſa had taken no great notice of him. However, Micipſa conſidering him as a prince of the blood, took as much care of him as he did of his own children.

7 History of Jugurtha.

Jugurtha poſſeſſed ſeveral eminent qualities, which gained him univerſal eſteem. He was very handſome, endued with great ſtrength of body, and adorned with the fineſt intellectual endowments. He did not devote himſelf, as young men commonly do, to a life of luxury and pleaſure. He uſed to exerciſe himſelf, with perſons of his age, in running, riding, hurling javelin, and other manly exerciſes, ſuited to the martial genius of the Numidians, and though he ſurpaſſed all his fellow ſportſmen, there was not one of them but loved him. The chaſe was his only delight; but it [illegible] that of lions and other ſavage beaſts. Salluſt, to [illegible] his character, tells us, that he excelled in all [illegible] ſpoke very little of himſelf.

[illegible]us an aſſemblage of fine talents and per[illegible] firſt charmed Micipſa, who thought them an ornament to his kingdom. However, he ſoon began to reflect, that he was conſiderably advanced in [illegible] children in their infancy; that mankind [illegible]rſted after power, and that nothing was [illegible]ing men run greater lengths than a vi[illegible] unlimited ambition. Theſe reflections ſoon [illegible] jealouſy, and determined him to expoſe Jugurtha to a variety of dangers, ſome of which, he entertained hopes, might prove fatal to him. In order to this, he gave him the command of a body of forces which he ſent to aſſiſt the Romans, who were at that time beſieging Numantia in Spain. But Jugurtha, by his admirable conduct, not only eſcaped all thoſe dangers, but likewiſe won the eſteem of the whole army, and the friendſhip of Scipio, who ſent a high character of him to his uncle Micipſa. However, that general gave him ſome prudent advice in relation to his future conduct; obſerving, no doubt, in him certain ſparks of ambition, which, if lighted into a flame, he apprehended might one day be productive of the moſt fatal conſequences.

8 Is dreaded by King Micipſa,

Before this laſt expedition, Micipſa had endeavoured to find out ſome method of taking him off privately; but his popularity amongſt the Numidians obliged that prince to lay aſide all thoughts of this nature. After his return from Spain the whole nation almoſt adored him. The heroic bravery he had ſhown there, his undaunted courage, joined to the utmoſt calmneſs of mind, which enabled him to preſerve a juſt medium between a timorous foreſight and an impetuous raſhneſs, a circumſtance rarely to be met with in perſons of his age, and above all the advantageous teſtimonials of his conduct given by Scipio, attracted an univerſal eſteem. Nay, Micipſa himſelf, charmed with the high opinion the Roman general had entertained of his merit, changed his behaviour towards him; reſolving, if poſſible, to win his affection by kindneſs. He therefore adopted him, and declared him joint heir with his two ſons to the crown. Finding, ſome few years afterwards, that his end approached, he ſent for all three to his bed ſide, where, in the preſence of the whole court, he deſired Jugurtha to recollect with what extreme tenderneſs he had treated him, and conſequently to conſider how well he had deſerved at his hands.

9 who nevertheleſs intruſts him with the care of his children,

He then entreated him to protect his children on all occaſions, who, being before related to him by the ties of blood, were now by their father's bounty be[illegible] his brethren. In order to fix him the more firmly [illegible]ir intereſt, he likewiſe complimented him upon his bravery, addreſs, and conſummate prudence. He further inſinuated, that neither arms nor treaſures conſtitute the ſtrength of a kingdom; but friends, who are neither won by arms nor gold, but by real ſervices and an inviolable fidelity. "Now, where (continued he) he) can we find better friends than in brothers? And how can that man who becomes an enemy to his relations, repoſe any confidence in, or depend upon ſtrangers?" Then addreſſing himſelf to Adherbal and Hiempſal, "And you (ſaid he) I enjoin always to pay the higheſt reverence to Jugurtha. Endeavour to imitate, and if poſſible ſurpaſs, his exalted merit, that the world may not hereafter obſerve Micipſa's adopted ſon to have reflected greater glory upon his memory than his own children." Soon after, Micipſa, who, according to Diodorus, was a prince of an amiable character, expired. Though Jugurtha did not believe the king to ſpeak his real ſentiments with regard to him, yet he ſeemed extremely pleaſed with ſo gracious [illegible], and made him an anſwer ſuitable to th[illegible] However, that prince at the ſame time was d[illegible] within himſelf to put in execution the ſcheme [illegible] formed at the ſiege of Numantia, which was ſuggeſt[illegible] to him by ſome factious and abandoned Roman officers, with whom he there contracted an acquaintance. The purport of this ſcheme was, that he ſhould extort the crown by force from his two couſins, as ſoon as their father's eyes were cloſed; which they inſinuated might eaſily be effected by his own valour, and the venality of the Romans. Accordingly, a ſhort time after the old king's death, he found means to aſſaſſinate Hiempſal in the city of Thirmida where his treaſures were depoſited, and drive Adherbal out of his dominions. That unhappy prince found himſelf obliged to fly to Rome, where he endeavoured to engage the conſcript fathers to eſpouſe his quarrel; but, notwithſtanding the juſtice of his cauſe, they had not virtue enough effectually to ſupport him. Jugurtha's ambaſſadors, by diſtributing vaſt ſums of money amongſt the ſenators, brought them ſo far over, that a majority palliated his inhuman proceedings. This encouraged thoſe miniſters to declare, that Hiempſal had been killed by the Numidians on account of his exceſſive cruelty; that Adherbal was the aggreſſor in the late troubles; and that he was only chagrined becauſe he could not make that havock among his countrymen he would willingly have done. They therefore entreated the ſenate to form a judgment of Jugurtha's behaviour in Africa from his conduct at Numantia, rather than from the ſuggeſtions of his enemies. Upon which, by far the greateſt part of the ſenate diſcovered themſelves prejudiced in his favour. A few, however, that were not loſt to honour, nor abandoned to corruption, inſiſted upon bringing him to condign puniſhment. But as they could not prevail, he had the beſt part of Numidia allotted him, and Adherbal was forced to reſt ſatisfied with the other.

10
one of whom he murders, and drives out the other.

11
enality of e Ro- s.

Jugurtha finding now by experience that every thing was venal at Rome, as his friends at Numantia had before informed him, thought he might purſue his towering projects without any obſtruction from that quarter. He therefore, immediately after the laſt diviſion of Micipſa's dominions, threw off the maſk, [illegible] attacked his couſin by open force. As Adherbal [illegible] a prince of a pacific diſpoſition, and almoſt in a[illegible] ſpects the reverſe of Jugurtha, he was by no means a match for him. The latter therefore pillaged the former's territories, ſtormed ſeveral of his fortreſſes, and overran a good part of his kingdom without oppoſition. Adherbal, depending on the friendſhip of the Romans, which his father in his laſt moments aſſured him would be a ſtronger ſupport to him than all the troops and treaſures in the univerſe, deſpatched deputies to Rome to complain of theſe hoſtilities. But whilſt he loſt his time in ſending thither fruitleſs deputations, Jugurtha overthrew him in a pitched battle, and ſoon after ſhut him up in Cirta. During the ſiege of this city, a Roman commiſſion arrived there, in order to perſuade both parties to an accommodation; but finding Jugurtha untractable, the commiſſioners returned home without ſo much as conferring with Adherbal. A ſecond deputation, compoſed of ſenators of the higheſt diſtinction, with Æmilius Scaurus, preſident of the [illegible] their head, landed ſome time after at Utica, and ſummoned Jugurtha to appear before them. That prince, at firſt ſeemed to be under dreadful apprehenſions, eſpecially as Scaurus reproached him with his enormous crimes, and threatened him with the reſentment of the Romans if he did not immediately [illegible]ſe the ſiege of Cirta. However, the Nu[illegible], by his addreſs, and the irreſiſtible power of [illegible] was afterwards ſuſpected at Rome, ſo molli[illegible], that he left Adherbal at his mercy. In [illegible] Jugurtha had at laſt Cirta ſurrendered to him, upon condition only that he ſhould ſpare the life of Adherbal. But the mercileſs tyrant, in violation of the laws of nature and humanity as well as the capitulation, when he had got poſſeſſion of the town, ordered him to be put to a moſt cruel death. The merchants likewiſe, and all the Numidians in the place capable of bearing arms, he cauſed without diſtinction to be put to the ſword.

Every perſon at Rome inſpired with any ſentiments of humanity, was ſtruck with horror at the news of this tragical event. However, all the venal ſenators ſtill concurred with Jugurtha's miniſters in palliating his enormous crimes. Notwithſtanding which, the people, excited thereto by Caius Memmius their tribune, who bitterly inveighed againſt the venality of the ſenate, reſolved not to let ſo flagrant an inſtance of villany go unpuniſhed. This diſpoſition in them induced the conſcript fathers likewiſe to declare their intention to chaſtiſe Jugurtha. In order to this, an army was levied to invade Numidia, and the command of it given to the conſul Calpurnius Beſtia, a perſon of good abilities, but rendered unfit for the expedition he was to go upon by his inſatiable avarice. Jugurtha being informed of the great preparations making at Rome to attack his dominions, ſent his ſon thither to avert the impending ſtorm. The young prince was plentifully ſupplied with money, which he had orders to diſtribute liberally amongſt the leading men. But Beſtia, propoſing to himſelf great advantages from an invaſion of Numidia, defeated all his intrigues, and got a decree paſſed, ordering him and his attendants to depart Italy in ten days, unleſs they were come to deliver up the king himſelf, and all his territories, to the republic by way of dedition. Which decree being [illegible]tified to them, they returned without ſo much as [illegible]aving entered the gates of Rome; and the conſul ſoon after landed with a powerful army in Africa. For ſome time he carried on the war there very briſkly, reduced ſeveral ſtrong holds, and took many Numidians priſoners. But upon the arrival of Scaurus, a peace was granted Jugurtha upon advantageous terms.

That

Numidia. That prince coming from Vacca, the place of his reſidence, to the Roman camp, in order to confer with Beſtia and Scaurus, and the preliminaries of the treaty being immediately after ſettled between them in private conferences, every body at Rome was convinced that the prince of the ſenate and the conſul had to their avarice ſacrificed the republic. The indignation thereof of the people in general diſplayed itſelf in the ſtrongeſt manner. Memmius alſo fired them with his ſpeeches. It was therefore reſolved to deſpatch the prætor Caſſius, a perſon they could confide in, to Numidia, to prevail upon Jugurtha to come to Rome, that they might learn from the king himſelf which of their generals and ſenators had been ſeduced by the peſtilent influence of corruption. Upon his arrival there, he found means to bribe one Bæbius Salca, a man of great authority amongſt the plebeians, but of inſatiable avarice, by whoſe aſſiſtance he eſcaped with impunity. Nay, by the efficacy of gold, he not only eluded all the endeavours of the people of Rome to bring him to juſtice, but likewiſe enabled Bomilcar, one of his attendants, to get Maſſiva, an [illegible] ſon of Micipſa, aſſaſſinated in the ſtreets of [illegible]. That young prince was adviſed by many Romans of probity, wellwiſhers to the family of Maſiniſſa, to apply for the kingdom of Numidia; which coming to Jugurtha's ears, he prevented the application by this execrable ſtep. However, he was obliged to leave Italy immediately.

Jugurtha had ſcarce ſet foot in Africa, when he received advice that the ſenate had annulled the ſhameful peace concluded with him by Beſtia and Scaurus. Soon after, the conſul Albinus tranſported a Roman army into Numidia, flattering himſelf with the hopes of reducing Jugurtha to reaſon before the expiration of his conſulate. In this, however, he found himſelf deceived; for that crafty prince, by various artifices ſo amuſed and impoſed upon Albinus, that nothing of moment happened that campaign. This rendered him ſtrongly ſuſpected of having betrayed his country, after the example of his predeceſſors. His brother Aulus, who ſucceeded him in the command of the army, was ſtill more unſucceſsful; for after riſing from before Suthul, where the king's treaſures were depoſited, he marched his forces into a defile out of which he found it impoſſible to extricate himſelf. He therefore was obliged to ſubmit to the ignominious ceremony of paſſing under the *jugum*, with all his men, and to quit Numidia entirely in ten days time, in order to deliver his troops from immediate deſtruction. The avaricious diſpoſition of the Roman commander had prompted him to beſiege Suthul, the poſſeſſion of which place he imagined would make him maſter of all the wealth of Jugurtha, and conſequently paved the way to ſuch a ſcandalous treaty. However, this was declared void as ſoon as known at Rome, as being concluded without the authority of the people. The Roman troops retired into Africa Propria, which they had now reduced into the form of a Roman province, and there took up their winter quarters.

In the mean time Caius Mamillius Limetanus, tribune of the people, excited the plebeians to inquire into the conduct of thoſe perſons by whoſe aſſiſtance Jugurtha had found means to elude all the decrees of the ſenate. This put the body of the people into a great ferment, which occaſioned a proſecution of the guilty ſenators, that was carried on, for ſome time, with the utmoſt heat and violence. Lucius Metellus the conſul, during theſe tranſactions, had Numidia aſſigned him for his province, and conſequently was appointed general of the army deſtined to act againſt Jugurtha. As he perfectly diſregarded wealth, the Numidian found him ſuperior to all his temptations; which was a great mortification to him. To this he joined all the other virtues which conſtitute the great captain; ſo that Jugurtha found him in all reſpects inacceſſible. That prince therefore was now forced to regulate his conduct according to the motions of Metellus with the greateſt caution; and to exert his utmoſt bravery, in order to compenſate for that hitherto ſo favourable expedient which now began to fail him. Marius, Metellus's lieutenant, being likewiſe a perſon of uncommon merit, the Romans reduced Vacca, a large opulent city, and the moſt celebrated mart in Numidia. They alſo defeated Jugurtha in a pitched battle; overthrew Bomilcar, one of his generals, upon the banks of the Muthullus; and, in fine, forced the Numidian monarch to take ſhelter in a place rendered almoſt inacceſſible by the rocks and woods with which it was covered. However, Jugurtha ſignalized himſelf in a ſurpriſing manner, exhibiting all that could be expected from the courage, abilities, and attention of a conſummate general, to whom deſpair adminiſters freſh ſtrength, and ſuggeſts new lights. But his troops could not make head againſt the Romans; they were again worſted by Marius, though they obliged Metellus to raiſe the ſiege of Zama. Jugurtha therefore, finding his country everywhere ravaged, his moſt opulent cities plundered, his fortreſſes reduced, his towns burnt, vaſt numbers of his ſubjects put to the ſword and taken priſoners, began to think ſeriouſly of coming to an accommodation with the Romans. His favourite Bomilcar, in whom he repoſed the higheſt confidence, but who had been gained over to the enemy by Metellus, obſerving this diſpoſition, found it no difficult matter to perſuade him to deliver up his elephants, money, arms, horſes, and deſerters, in whom the main ſtrength of his army conſiſted, into the hands of the Romans. Some of theſe laſt, in order to avoid the puniſhment due to their crime, retired to Bocchus king of Mauritania, and liſted in his ſervice. But Metellus ordering him to repair to Tiſidium, a city of Numidia, there to receive farther directions, and he refuſing a compliance with that order, hoſtilities were renewed with greater fury than ever. Fortune now ſeemed to declare in favour of Jugurtha: he retook Vacca, and maſſacred all the Roman garriſon, except Turpilius the commandant. However, ſoon after, a Roman legion ſeized again upon it, and treated the inhabitants with the utmoſt ſeverity. About this time, one of Maſtanabal's ſons, named *Gauda*, whom Micipſa in his will had appointed to ſucceed to the crown in caſe his two legitimate ſons and Jugurtha died without [illegible] to the ſenate in favour of Marius, who [illegible] to ſupplant Metellus. That prince [illegible] ſtanding impaired by a declining ſtate of [illegible] a more eaſy prey to the baſe and infamous adulation of Marius. The Roman, ſoothing his vanity, aſſured him, that as he was the next heir to the crown, he might depend upon being

Numidia.

12 Metellus ſent againſt Jugurtha.

13 Who is betrayed by Bomilcar.

fixed upon the Numidian throne, as ſoon as Jugurtha was either killed or taken; and that this would in a ſhort time happen, when once he appeared at the head of the Roman army with an unlimited commiſſion. Soon after, Bomilcar and Nabdalſa formed a deſign to aſſaſſinate Jugurtha, at the inſtigation of Metellus; but this being detected, Bomilcar and moſt of his accomplices ſuffered death. The plot however had ſuch an effect upon Jugurtha, that he enjoyed afterwards no tranquillity or repoſe. He ſuſpected perſons of all denominations, Numidians as well as foreigners, of ſome black deſigns againſt him. Perpetual terrors ſat brooding over his mind; inſomuch that he never got a wink of ſleep but by ſtealth, and often changed his bed in a low plebeian manner. Starting from his ſleep, he would frequently ſnatch his ſword, and break out into the moſt doleful cries: So ſtrongly was he haunted by a ſpirit of fear, jealouſy, and diſtraction!

14 A conſpiracy againſt him.

Jugurtha having deſtroyed great numbers of his friends on ſuſpicion of their having been concerned in the late conſpiracy, and many more of them deſerting to the Romans and Bocchus king of Mauritania, he found himſelf, in a manner, deſtitute of counſellors, generals, and all perſons capable of aſſiſting him in carrying on the war. This threw him into a deep melancholy, which rendered him diſſatisfied with every thing, and made him fatigue his troops with a variety of contradictory motions. Sometimes he would advance with great celerity againſt the enemy, and at others retreat with no ſmall ſwiftneſs from them. Then he reſumed his former courage; but ſoon after deſpaired either of the valour or fidelity of the forces under his command. All his movements therefore proved unſucceſsful, and at laſt he was forced by Metellus to a battle. That part of the Numidian army which Jugurtha commanded, behaved with ſome reſolution; but the other fled at the firſt onſet. The Romans therefore entirely defeated them, took all their ſtandards, and made a few of them priſoners. But few of them were ſlain in the action; ſince, as Salluſt obſerves, the Numidians truſted more to their heels than to their arms for ſafety in this engagement.

15 He is defeated by Metellus.

Metellus purſued Jugurtha and his fugitives to Thala. His march to this place being through vaſt deſerts, was extremely tedious and difficult. But being ſupplied with leathern bottles and wooden veſſels of all ſizes taken from the huts of the Numidians, which were filled with water brought by the natives, who had ſubmitted to him, he advanced towards that city. He had no ſooner begun his march, than a moſt copious ſhower of rain, a thing very uncommon in thoſe deſerts, proved a great and ſeaſonable refreſhment to his troops. This ſo animated them, that upon their arrival before Thala, they attacked the town with ſuch vigour, that Jugurtha with his family, and treaſures depoſited therein, thought proper to abandon it. After a brave defence, it was reduced; the garriſon, conſiſting of Roman deſerters, ſetting fire to the king's palace, and conſuming themſelves, together with every thing valuable to them, in the [illegible] gurtha, being now reduced to [illegible] tired [illegible] innumerable [illegible] to the confines of Mauritania; and engaged Bocchus king of that country, who had married his daughter, to enter into an alliance with him. In conſequence of which, having reinforced his Gætulian troops with a powerful body of Mauritanians, he turned the tables upon Metellus, and obliged him to keep cloſe within his entrenchments. Salluſt informs us, that Jugurtha bribed Bocchus's miniſters to influence that prince in his favour; and that having obtained an audience, he inſinuated, that, ſhould Numidia be ſubdued, Mauritania muſt be involved in its ruin, eſpecially as the Romans ſeemed to have vowed the deſtruction of all the thrones in the univerſe. In ſupport of what he advanced, he produced ſeveral inſtances very appoſite to the point in view. However, the ſame author ſeems to intimate, that Bocchus was determined to aſſiſt Jugurtha againſt his enemies by the ſlight the Romans had formerly ſhown him. That prince, at the firſt breaking out of the war, had ſent ambaſſadors to Rome, to propoſe an offenſive and defenſive alliance to the republic; which, though of the utmoſt conſequence to it at the juncture, a few of the moſt venal and infamous ſenators, who were abandoned to corruption, prevented from taking effect. This undoubtedly wrought more powerfully upon Bocchus in favour of Jugurtha, than the relation he ſtood in to him: For both the Moors and Numidians adapted the number of their wives to their circumſtances, ſo that ſome had 10, 20, &c. to their ſhare; their kings therefore were unlimited in this particular, and of courſe all degrees of affinity reſulting to them from marriage had little force. It is obſervable, that the poſterity of thoſe ancient nations have the ſame cuſtom prevailing amongſt them at this day.

Such was the ſituation of affairs in Numidia, when Metellus received advice of the promotion of Marius to the conſulate. But, notwithſtanding this injurious treatment, he generouſly endeavoured to draw off Bocchus from Jugurtha, though this would facilitate the reduction of Numidia for his rival. To this end ambaſſadors were deſpatched to the Mauritanian court, who intimated to Bocchus, "That it would be highly imprudent to come to a rupture with the Romans without any cauſe at all; and that he had now a fine opportunity of concluding a moſt advantageous treaty with them, which was much preferable to a war. To which they added, that whatever dependence he might place upon his riches, he ought not to run the hazard of loſing his dominions by embroiling himſelf with other ſtates, when he could eaſily avoid this; that it was much eaſier to begin a war than to end it, which it was in the power of the victor alone to do; that, in fine, he would by no means conſult the intereſt of his ſubjects if he followed the deſperate fortunes of Jugurtha." To which Bocchus replied, "That for his part there was nothing he wiſhed for more than peace; but that he could not help pitying the deplorable condition of Jugurtha; that if the Romans, therefore, would grant that unfortunate prince the ſame terms they had offered him, he would bring about an accommodation." Metellus, let the Mauritanian monarch know, that it was not in his power to comply with what he deſired. However, he took care to keep up a private negotiation with him till the new conſul Marius's arrival. By this conduct he ſerved two wiſe ends. Firſt, He prevented thereby Bocchus from coming to a general action with his

16 Marius ſucceeds Metellus.

troops; which was the very thing Jugurtha deſired, as hoping that this, whatever the event might be, would render a reconciliation betwixt him and the Romans impracticable. Secondly, This inaction enabled him to diſcover ſomething of the genius and diſpoſition of the Moors; a nation of whom the Romans, till then, had ſcarce formed any idea; which, he imagined, might be of no ſmall ſervice, either to himſelf or his ſucceſſors, in the future proſecution of the war.

Jugurtha, being informed that Marius, with a numerous army, was landed at Utica, adviſed Bocchus to retire, with part of the troops, to ſome place of difficult acceſs, whilſt he himſelf took poſt upon another inacceſſible ſpot with the remaining corps. By this meaſure, he hoped the Romans would be obliged to divide their forces, and conſequently be more expoſed to his efforts and attacks. He likewiſe imagined, that ſeeing no formidable body appear, they would believe the enemy in no condition to make head againſt them; which might occaſion a relaxation of diſcipline, the uſual attendant of a too great ſecurity, and conſequently produce ſome good effects. However, he was diſappointed in both theſe views. For Marius, far from ſuffering a relaxation of diſcipline to take place, trained up his troops, which conſiſted chiefly of new levies, in ſo perfect a manner, that they were ſoon equal in goodneſs to any conſular army that ever appeared in the field. He alſo cut off great numbers of the Gætulian marauders, defeated many of Jugurtha's parties, and had like to have taken that prince himſelf near the city of Cirta. These advantages, though not of any great importance, intimidated Bocchus, who now made overtures for an accommodation; but the Romans, not being ſufficiently ſatisfied of his ſincerity, paid no great attention to them. In the mean time Marius puſhed on his conqueſts, reducing ſeveral places of leſs note, and at laſt reſolved to beſiege Capſa. That this enterpriſe might be conducted with the greater ſecrecy, he ſuffered not the leaſt hint of his deſign to tranſpire, even amongſt any of his officers. On the contrary, in order to blind them, he detached A. Manlius, one of his lieutenants, with ſome light-armed cohorts, to the city of Lares, where he had fixed his principal magazine, and depoſited the military cheſt. Before Manlius left the camp, that he might the more effectually amuſe him, he intimated, that himſelf with the army ſhould take the ſame route in a few days: but inſtead of that, he bent his march towards the Tanais, and in ſix days time arrived upon the banks of that river. Here he pitched his tents for a ſhort time, in order to refreſh his troops; which having done, he advanced to Capſa, and made himſelf maſter of it. As the ſituation of this city rendered it extremely commodious to Jugurtha, whoſe plan of operations, ever ſince the commencement of the war, it had exceedingly favoured, he levelled it with the ground after it had been delivered up to the ſoldiers to be plundered. The citizens likewiſe, being more ſtrongly attached to that prince than any of the other Numidians, on account of the extraordinary privileges he indulged them with, and of courſe bearing a more implacable hatred to the Romans, he put to the ſword or ſold for ſlaves. The true motive of the conſul's conduct on this occaſion ſeems here to be aſſigned; though we are told by Salluſt, in conformity to the Roman genius, that neither avarice nor reſentment prompted him to ſo barbarous an action, but only a deſire to ſtrike a terror into the Numidians.

17 He gains a great advantage over Jugurtha.

The Numidians, ever after this exploit, dreaded the very name of Marius; who now, in his own opinion, had eclipſed the glory of all his predeceſſor's great atchievements, particularly the reduction of Thala, a city, in ſtrength and ſituation, nearly reſembling Capſa. Following this blow, he gradually preſented himſelf before moſt of the places of ſtrength in the enemy's country, many of which either opened their gates, or were [illegible], at his approach, being terrified with what had happened to the unfortunate citizens of Capſa. Others taken by force, he laid in aſhes; and in [illegible] filled the greateſt part of Numidia with blood, [illegible] and confuſion. Then, after an obſtinate defence, he reduced a caſtle that ſeemed impregnable, ſeated not far from Mulucha, where Jugurtha kept part of his treaſures. In the mean time, Jugurtha not being able to prevail upon Bocchus, by his repeated ſolicitations, to advance into Numidia, where he found himſelf greatly preſſed, was obliged to have recourſe to his uſual method of bribing the Mauritanian miniſters, in order to put that prince in motion. He alſo promiſed him a third part of his kingdom, provided they could either drive the Romans out of Africa, or get all the Numidian dominions confirmed to him by treaty.

So conſiderable a ceſſion could not fail of engaging Bocchus to ſupport Jugurtha with his whole power. The two African monarchs therefore, having joined their forces, ſurpriſed Marius near Cirta as he was going into winter quarters. The Roman general was ſo puſhed on this occaſion, that the barbarians thought themſelves certain of victory, and doubted not but they ſhould be able to extinguiſh the Roman name in Numidia. But their incaution and too great ſecurity enabled Marius to give them a total defeat; which was followed four days after by ſo complete an overthrow, that their numerous army, conſiſting of 90,000 men, by the acceſſion of a powerful corps of Moors, commanded by Bocchus's ſon Volux, was entirely ruined. Sylla, Marius's lieutenant, moſt eminently diſtinguiſhed himſelf in the laſt action, which laid the foundation of his future greatneſs. Bocchus, now looking upon Jugurtha's condition as deſperate, and not being willing to run the riſk of loſing his dominions, ſhowed a diſpoſition to clap up a peace with Rome. However, the republic gave him to underſtand, that he muſt not expect to be ranked amongſt its friends, till he had delivered up into the conſul's hands Jugurtha, the inveterate enemy of the Roman name. The Mauritanian monarch, having entertained a high idea of an alliance with that ſtate, reſolved to ſatisfy it in this particular; and was confirmed in his reſolution by one Dabar, a Numidian prince, the ſon of Maſſugrada, and deſcended by his mother's ſide from Maſiniſſa. Being cloſely attached to the Romans, and extremely agreeable to Bocchus on account of his noble diſpoſition, he defeated all the intrigues of Aſpar, Jugurtha's miniſter. Upon Sylla's arrival at the Mauritanian court, the affair there ſeemed to be entirely ſettled. However, Bocchus, who was for ever projecting new deſigns,

18 Jugurtha entirely defeated.

deſigns, and, like the reſt of his countrymen, in the higheſt degree perfidious, debated within himſelf, whether he ſhould ſacrifice Sylla or Jugurtha, who were both then in his power. He was a long time fluctuating with uncertainty, and combated by a contrariety of ſentiments. The ſudden changes which diſplayed themſelves in his countenance, his air, and his whole perſon, evidently ſhowed how ſtrongly his mind was agitated. But at laſt he returned to his firſt deſign, to which the bias of his mind ſeemed naturally to lead him. He therefore delivered up Jugurtha into the hands of Sylla, to be conducted to Marius; who, by that ſucceſsful event, happily terminated this dangerous war. The kingdom of Numidia was now reduced to a new form: Bocchus, for his important ſervices, had the country of the Maſſæſyli, contiguous to Mauritania, aſſigned him: which, from this time, took the name of *New Mauritania.* Numidia Propria, or the country of the Maſſyli, was divided into three parts; one of which was given to Hiempſal, another to Mandreſtal, both deſcendants of Maſiniſſa; and the third the Romans annexed to Africa Propria, or the Roman province adjacent to it. What became of Jugurtha after he had graced Marius's triumph, at which ceremony he was led in chains, together with his two ſons, through the ſtreets of Rome, we have already laid before our readers. See JUGURTHA.

20
Tranſactions after the death of Jugurtha.

Jugurtha's two ſons ſurvived him, but ſpent their lives in captivity at Venuſia. However, one of them, named *Oxyntas*, was, for a ſhort time, releaſed from his confinement by Aponius, who beſieged Acerræ in the war between the Romans and the Italian allies. That general brought this prince to his army, where he treated him as king, in order to draw the Numidian forces off from the Roman ſervice. Accordingly thoſe Numidians no ſooner heard that the ſon of their old king was fighting for the allies, than they began to deſert by companies; which obliged Julius Cæſar the conſul to part with all his Numidian cavalry, and ſend them back into Africa. Some few years after this event, Pompey defeated Cneius Domitius Ahenobarbus, and Hiarbas one of the kings of Numidia, killing 17,000 of their men upon the ſpot. Not ſatisfied with this victory, that general purſued the fugitives to their camp, which he ſoon forced, put Domitius to the ſword, and took Hiarbas priſoner. He then reduced that part of Numidia which belonged to Hiarbas, who ſeems to have ſucceeded Mandreſtal abovementioned; and gave it to Hiempſal, a neighbouring Numidian prince, deſcended from Maſſiniſſa, who had always oppoſed the Marian faction.

21
Cæſar inſults Juba.

Suetonius informs us, that a diſpute happened between Hiempſal and one Maſintha, a noble Numidian, whom, it is probable, he had in ſome reſpect injured when Julius Cæſar firſt began to make a figure in the world. The ſame author adds, that Cæſar warmly eſpouſed the cauſe of Maſintha, and even groſsly inſulted Juba, Hiempſal's ſon, when he attempted to vindicate his father's conduct on this occaſion. He pulled him by the beard, than which a more unpardonable affront could not be offered to an African. In ſhort, he ſcreened Maſintha from the inſults and violence of his enemies; from whence a reaſon may be aſſigned for Juba's adhering ſo cloſely afterwards to the Pompeian faction.

22
Juba defeats one of Cæſar's lieutenants.

In conſequence of the indignity Cæſar had offered Juba, and the diſpoſition it had occaſioned, that prince did Cæſar great damage in the civil wars betwixt him and Pompey. By a ſtratagem he drew Curio, one of his lieutenants, into a general action, which it was his intereſt at that time to have avoided. He cauſed it to be given out all over Africa Propria and Numidia, that he was retired into ſome remote country at a great diſtance from the Roman territories. This coming to Curio's ears, who was then beſieging Utica, it hindered him from taking the neceſſary precautions againſt a ſurpriſe. Soon after, the Roman general receiving intelligence that a ſmall body of Numidians was approaching his camp, he put himſelf at the head of his forces in order to attack them, and, for fear they ſhould eſcape, began his march in the night, looking upon himſelf as ſure of victory. Some of their advanced poſts he ſurpriſed aſleep, and cut them to pieces; which ſtill farther animated him. In ſhort, about day break he came up with the Numidians, whom he attacked with great bravery, though his men were then faſting, and vaſtly fatigued by their forced and precipitate march. In the mean time, Juba, who, immediately after the propagation of the rumour above mentioned, had taken care to march privately, with the main body of the Numidian army, to ſupport the detachment ſent before to decoy Curio, advanced to the relief of his men. The Romans had met with a great reſiſtance before he appeared; ſo that he eaſily broke them, killed Curio, with a great part of his troops, upon the ſpot, purſued the reſt to their camp, which he plundered, and took many of them priſoners. Moſt of the fugitives, who endeavoured to make their eſcape on board the ſhips in the port of Utica, were either ſlain by the purſuers, or drowned. The remainder fell into the hands of Varus, who would have ſaved them; but Juba, who arrogated to himſelf the honour of this victory, ordered moſt of them to be put to the ſword.

23
Juba overthrown by Cæſar.

This victory infuſed new life and vigour into the Pompeian faction, who thereupon conferred great honours upon Juba, and gave him the title of *king of all Numidia.* But Cæſar and his adherents declared him an enemy to the ſtate of Rome, adjudging to Bocchus and Bogud, two African princes entirely in their intereſt, the ſovereignty of his dominions. Juba afterwards, uniting his forces with thoſe of Scipio, reduced Cæſar to great extremities, and would in all probability have totally ruined him, had he not been relieved by Publius Sittius. That general, having formed a conſiderable corps, conſiſting of Roman exiles, and Mauritanian troops ſent him by Bocchus, according to Dio, or, as Cæſar will have it, Bogud, made an irruption into Gætulia and Numidia, whilſt Juba was employed in Africa Propria. As he ravaged theſe countries in a dreadful manner, Juba immediately returned with the beſt part of his army, to preſerve them from utter deſtruction. However, Cæſar knowing his horſe to be afraid of the enemy's elephants, did not think proper to attack Scipio in the abſence of the Numidian, till his own elephants, and a freſh reinforcement of troops, hourly expected, arrived from

Italy. With this acceſſion of ſtrength, he imagined himſelf able to give a good account, both of the Roman forces with which he was to cope, and the barbarians. In the mean time Scipio deſpatched reiterated expreſſes to Juba to haſten to his aſſiſtance; but could not prevail upon him to move out of Numidia, till he had promiſed him the poſſeſſion of all the Roman dominions in Africa, if they could from thence expel Cæſar. This immediately put him in motion; ſo that, having ſent a large detachment to make head againſt Sittius, he marched with the reſt of his troops to aſſiſt Scipio. However, Cæſar at laſt overthrew Scipio, Juba, and Labienus, near the town of Thapſus, and forced all their camps. As Scipio was the firſt ſurpriſed and defeated, Juba fled into Numidia without waiting for Cæſar's approach; but the body of the Numidians detached againſt Sittius, having been broken and diſperſed by that general, none of his ſubjects there would receive him. Abandoned therefore to deſpair, he ſought death in a ſingle combat with Petreius, and having killed him, cauſed himſelf to be diſpatched by one of his ſlaves.

24 Numidia reduced to the form of a province.

After this deciſive action, and the reduction of Africa Propria, Cæſar made himſelf maſter of Numidia, which he reduced to a Roman province, appointing Criſpus Salluſtius to govern it in quality of proconſul, with private inſtructions to pillage and plunder the inhabitants, and, by that means, put it out of their power ever to ſhake off the Roman yoke. However, Bocchus and Bogud ſtill preſerved a ſort of ſovereignty in the country of the Maſſæſyli and Mauritania, ſince the former of thoſe princes, having deſerted Cæſar, ſent an army into Spain to aſſiſt the Pompeians; and the latter, with his forces, determined victory to declare for Cæſar at the ever memorable battle of Munda. Bogud, afterwards ſiding with Antony againſt Octavius, ſent a body of forces to aſſiſt him in Spain; at which time the Tingitanians revolting from him, Bocchus, with an army compoſed of Romans in the intereſt of Octavius, who paſſed over from Spain into Africa, and his own ſubjects, poſſeſſed himſelf of Mauritania Tingitana. Bogud fled to Antony; and Octavius, after the concluſion of the war, honoured the inhabitants of Tingi with all the privileges of Roman citizens. He likewiſe confirmed Bocchus king of Mauritania Cæſarienſis, or the country of the Maſſæſyli, in the poſſeſſion of Tingitania, which he had conquered, as a reward for his important ſervices. In this he imitated the example of his great predeceſſor Julius Cæſar, who divided ſome of the fruitful plains of Numidia among the ſoldiers of P. Sittius, who had conquered great part of that country, and appointed Sittius himſelf ſovereign of that diſtrict. Sittius, as has been intimated above, having taken Cirta, killed Sabura, Juba's general, entirely diſperſed his forces, and either cut off or taken priſoners moſt of the Pompeian fugitives that eſcaped from the battle of Thapſus, highly deſerved to be diſtinguiſhed in ſo eminent a manner. After Bocchus's death, Mauritania and the Maſſæſylian Numidia were in all reſpects conſidered Roman provinces.

NUMISMATOGRAPHIA, a term uſed for the deſcription and knowledge of ancient coins and medals, whether of gold, ſilver, or braſs. See COINS and MEDALS.

NUMITOR, the ſon of Procas king of Alba, and the brother of Amulius. Procas before his death made him and Amulius joint heirs to the crown, on condition of their reigning annually by turns: but Amulius, on getting poſſeſſion of the throne, excluded Numitor, whoſe ſon Lauſus he ordered to be put to death, and obliged Rhea Sylvia, Numitor's only daughter, to become a veſtal. This princeſs becoming pregnant, declared that ſhe was with child by the god Mars; and afterwards brought forth Remus and Romulus, who at length killed Amulius, and reſtored Numitor to the throne [illegible] C. See REMUS and ROMULUS.

[illegible] a piece of money otherwiſe called *ſeſte*

NUN, the ſon of Eliſhamah, and father of Joſhua, of the tribe of Ephraim. The Greeks gave him the name of *Nane* inſtead of Nun. This man is known in ſacred hiſtory only by being the father of Joſhua.

NUN, a woman, in ſeveral Chriſtian countries, who devotes herſelf, in a cloiſter or nunnery, to a religious life. See the article MONK.

There were women, in the ancient Chriſtian church, who made public profeſſion of virginity, before the monaſtic life was known in the world, as appears from the writings of Cyprian and Tertulian. Theſe, for diſtinction's ſake, are ſometimes called *eccleſiaſtical virgins*, and were commonly enrolled in the canon or matricula of the church. They differed from the monaſtic virgins chiefly in this, that they lived privately in their fathers houſes, whereas the others lived in communities: but their profeſſion of virginity was not ſo ſtrict as to make it criminal for them to marry afterwards, if they thought fit. As to the conſecration of virgins, it had ſome things peculiar in it: it was uſually performed publicly in the church by the biſhop. The virgin made a public profeſſion of her reſolution, and then the biſhop put upon her the accuſtomed habit of ſacred virgins. One part of this habit was a veil, called the *ſacrum velamen*; another was a kind of mitre or coronet worn upon the head. At preſent, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and ſhe herſelf, accompanied by her neareſt relations, is conducted to the biſhop, who, after maſs and an anthem, (the ſubject of which is, "that ſhe ought to have her lamp lighted, becauſe the bridegroom is coming to meet her)," pronounces the benediction: then ſhe riſes up, and the biſhop conſecrates the new habit, ſprinkling it with holy water. When the candidate has put on her religious habit, ſhe preſents herſelf before the biſhop, and ſings, on her knees, *Ancilla Chriſti ſum*, &c.; then ſhe receives the veil, and afterwards the ring, by which ſhe is married to Chriſt; and laſtly, the crown of virginity. When ſhe is crowned, an anathema is denounced againſt all who ſhall attempt to make her break her vows. In ſome few inſtances, perhaps, it may have happened that nunneries, monaſteries, &c. may have been uſeful as well to morality and religion as to literature: in the groſs, however, they have been highly prejudicial; and however well they might be ſuppoſed to do when viewed in theory, in fact they are unnatural and impious. It was ſurely far from the intention of Providence to ſeclude youth and beauty in a cloiſtered ruin, or to deny them the innocent enjoyment [illegible] years and ſex.

NUNCIO, or NUNTIO, an ambaſſador from the pope to ſome Catholic prince or ſtate, or a perſon who attends on the pope's behalf at a congreſs, or an aſſembly of ſeveral ambaſſadors.

NUNCUPATIVE, in the ſchools, ſomething that is only nominal, or has no exiſtence but in name.

Nuncupative Will or *Teſtament*, a will made verbally, and not put in writing. See the articles WILL and TESTAMENT.

NUNDINA, a goddeſs among the ancient heathens, ſuppoſed to have the care of the purification of infants. And becauſe male infants were purified nine days after their birth, her name is derived from *nonus*, or the ninth, though female infants were purified the eighth day; which purification was called *luſtration* by the Romans.

NUNDINAL, *Nundinalis*, a name which the Romans gave to the eight firſt letters of the alphabet uſed in their kalendar.

This ſeries of letters, A, B, C, D, E, F, G, H, is placed and repeated ſucceſſively from the firſt to the laſt day of the year: one of theſe always expreſſed the market days, or the aſſemblies called *nundinæ, quaſi novendinæ*, becauſe they returned every nine days. The country people, after working eight days ſucceſſively, came to town the ninth, to ſell their ſeveral commodities, and to inform themſelves of what related to religion and government. Thus the nundinal day being under A on the firſt, ninth, ſeventeenth, and twenty fifth days of January, &c. the letter D will be the nundinal letter of the year following. Theſe nundinals bear a very great reſemblance to the dominical letters, which return every eight days, as the nundinal did every nine.

NUNDOCOMAR, a Rajah in Bengal, and head of the Bramins, who, in 1775, was condemned to an ignominious death by Engliſh laws newly introduced in an Engliſh court of juſtice newly eſtabliſhed, for a forgery charged to have been committed by him many years before. That he was guilty of the deed cannot be queſtioned; but there was ſurely ſomething hard in condemning a man by an *ex poſt facto* law. He bore his fate with the utmoſt fortitude, in the full confidence that his ſoul would ſoon be reunited to the univerſal ſpirit whence it had ſprung. See METAPHYSICS, Part III. Ch. IV. *Of the Immortality of the Soul.*

Monte Nuovo, in the environs of Naples, blocks up the valley of Averno. "This mountain (Mr Swinburne tells us) aroſe in the year 1538, for after repeated quakings, the earth burſt aſunder, and made way for a deluge of hot aſhes and flames, which riſing extremely high, and darkening the atmoſphere, fell down again and formed a circular mound four miles in circumference, and 1000 feet high, with a large cup in the middle. The wind riſing afterwards, wafted the lighter particles over the country, blaſted vegetation, and killed the animals who grazed. The conſequence was, that the place was deſerted, till Don Pedro de Toledo, viceroy of Naples, encouraged the inhabitants by example and otherwiſe to return.

"Part of Monte Nuovo is cultivated, but the larger portion of its declivity is wildly overgrown with prickly broom, and rank weeds that emit a very fetid ſulphureous ſmell. The crater is ſhallow, its inſide clad with ſhrubs, and the little area at the bottom planted with fig and mulberry trees; a moſt ſtriking ſpecimen of the amazing viciſſitudes that take place in this extraordinary country. I ſaw no traces of lava or melted matter, and few ſtones within.

"Near the foot of this mountain the ſubterraneous fires act with ſuch immediate power, that even the ſand at the bottom of the ſea is heated to an intolerable degree."

NUPTIAL RITES, the ceremonies attending the ſolemnization of marriage, which are different in different ages and countries. We cannot omit here a cuſtom which was practiſed by the Romans on theſe occaſions; which was this: Immediately after the chief ceremonies were over, the new married man threw *nuts* about the room for the boys to ſcramble for. Various reaſons have been aſſigned for it; but that which moſt generally prevails, and ſeems to be the moſt juſt, is, that by this act the bridegroom ſignified his reſolution to abandon trifles, and commence a ſerious courſe of life; whence *nucibus relictis* in this ſenſe became a proverb. They might alſo be an emblem of fertility.

The ancient Greeks had a perſon to conduct the bride from her own to the bridegroom's houſe, and hence he was called by the Greeks *Nymphagogos*, which term was afterwards uſed both by the Romans and the Jews.

NUREMBERG, an imperial city of Germany, capital of a territory of the ſame name, ſituated in E. Long. 11°, N. Lat. 47. 30. It ſtands on the Regnitz, over which it has ſeveral bridges, both of wood and ſtone, at the bottom of a hill, 60 miles from Augſburg, 87 from Munich, 46 from Wurtzburg, and 50 from Ratiſbon; and is thought by ſome to be the Segodunum, and by others the Caſtrum Noricum of the ancients.

The city has derived its name from the hill, upon which ſtands the caſtle, called, in Latin, Caſtrum Noricum, round which the city was begun to be built, and where the emperors formerly lodged, and here they lodge ſtill, when they paſs by that city. They there preſerve, as precious relicks, the crown, ſceptre, clothes, buſkins, and other ornaments of Charlemagne (A), which ſerved alſo the emperor Leopold, when he went thither after his election, to receive the homage of the city. The ſmall river Regnitz, which runs through it, and thoſe of Rednitz and Schwartzack, which paſs by its walls, furniſh the inhabitants, beſides other advantages, with the means of making all ſorts of ſtuffs, dyes, and other manufactures (B).

(A) Theſe ornaments are, a mitred crown, enriched with rubies, emeralds, and pearls; the dalmatic of Charlemagne, richly embroidered, the imperial mantle powdered, with embroidered eagles, and its border thick ſet with large emeralds, ſapphires, and topazes; the buſkins covered with plates of gold, the gloves embroidered, the apple, the golden ſceptre, and ſword. The ancient cuſtom of the empire is, that the emperor is bound to aſſemble in this city the firſt diet that he holds after his election and coronation.

(B) There is in Nuremberg, and in the neighbouring villages depending upon it, an infinite number of workmen and toys, which are carried and ſold even in the Indies.

It is a large and well built town, but not very populous. Its fortifications are a double wall, flanked with towers mounting cannon, and a deep ditch. The magiſtrates, and moſt of the inhabitants, are Lutherans. There are a great many churches and chapels in it. In that of St Sebald is a braſs monument of the ſaint; and a picture, repreſenting the creation of the world, by the celebrated Albert Durer, who was a native of the town; but the fineſt church in the town is that of St Giles. In that of the Holy Ghoſt are kept moſt of the jewels of the empire, together with the pretended ſpear with which our Saviour's ſide was pierced, a thorn of his crown, and a piece of the manger wherein he was laid. Here are alſo a great many hoſpitals, one in particular for foundlings, and another for pilgrims; with a gymnaſium, an anatomical theatre, a granary, a fine public library, the old imperial fortreſs or caſtle, ſome remains of the old citadel of the burgraves of Nuremberg, ſeveral Latin ſchools, an academy of painting, a well furniſhed arſenal, a Teutonic houſe in which the Roman Catholic ſervice is tolerated, and a mint. Mr Keyſler ſays, there are upwards of 500 ſtreets in it, about 140 fountains, 16 churches, 44 religious houſes, 12 bridges, 10 market places, and 25,000 inhabitants; and that its territories, beſides the capital and four other towns, contain above 500 villages, and about 160 mills on the Regnitz. The trade of this city, though upon the decline, is ſtill very great, many of its manufactures being ſtill exported to all parts of the world; among which may be reckoned a great variety of curious toys in ivory, wood, and metal, already mentioned. The city has alſo diſtinguiſhed itſelf in the arts of painting and engraving. When the emperor Henry VI. aſſiſted at a tournament in Nuremberg, he raiſed 38 burghers to the degree of nobility, the deſcendants of whom are called *patricians*, and have the government of the city entirely in their hands; the whole council, except eight maſters of companies, who are ſummoned only on extraordinary occaſions, conſiſting of them. Among the fine braſs cannon in the arſenal, is one that is charged at the breech, and may be fired eight times in a minute; and two that carry balls of eighty pounds. The city keeps, in conſtant pay, ſeven companies, conſiſting each, in time of peace, of 100 men, but, in time of war, of 185; two troops of cuiraſſiers, each conſiſting of 85 men; and two companies of invalids. There are alſo 24 companies of burghers, well armed and diſciplined. On the new bridge, which is ſaid to have coſt 100,000 guilders, are two pyramids, on the top of one of which is a dove with an olive branch in her bill, and on the other an imperial black eagle. Muſic alſo flouriſhes greatly in Nuremberg; and thoſe who delight in mechanic arts and manufactures cannot anywhere better gratify their curioſity. As an imperial city, it has a ſeat and voice at the diets of the empire and circle, paying to the chamber of Wetzlar 812 rixdollars each term. The territory belonging to the city is pretty large, containing, beſides two conſiderable foreſts of pine, called the *Sebald* and *Laurence foreſts*, ſeveral towns and villages.

We have mentioned already that certain families called patricians, to the excluſion of the reſt, poſſeſs the offices of the ſenate. They are compoſed of 42 perſons (c), over which two caſtellans, or perpetual ſeneſchals, preſide, the firſt of whom has his reſidence in the caſtle. Theſe caſtellans aſſemble ſometimes in the caſtle, with five or ſix of the chief members, to hold a ſecret council (d). And, as this city glories in being one of the firſt which embraced Lutheraniſm, it preſerves the privilege of that in civil matters, not admitting any Catholics to the magiſtracy or freedom of the town; the Catholics there having the liberty only of remaining under the protection of the reſt, and performing their religious worſhip in a commandery of Malta, and this but at certain hours, not to diſturb the Lutherans, who likewiſe aſſemble there, although in poſſeſſion of all the other churches.

This city is particularly noted for its antiquity, grandeur, fortifications, its triple walls of hewn ſtone, its large and deep moat, its fine houſes, large churches, its wide ſtreets, always clean, and for its curious and large library, and its magazine ſtored with every thing proper for its defence.

NURSERY, in gardening, is a piece of land ſet apart for raiſing and propagating all ſorts of trees and plants to ſupply the garden and other plantations.

NURSING OF CHILDREN. See LACTATIO.

The following obſervations are ſaid to be the reſult of long experience †. A child, when it comes into the world, is almoſt a round ball; it is the nurſe's part to aſſiſt nature, in bringing it to a proper ſhape. The child ſhould be laid (the firſt month) upon a thin mattreſs, rather longer than itſelf, which the nurſe will keep upon her lap, that the child may always lie ſtraight, and only ſit up as the nurſe ſlants the mattreſs. To ſet a child quite upright before the end of the firſt month, hurts the eyes, by making the white part of the eye appear below the upper eyelid. Afterwards the nurſe will begin to ſet it up and dance it by degrees. The child muſt be kept as dry as poſſible.

† An. Reg. Vol. VI. p. 130.

The clothing ſhould be very light, and not much longer than the child, that the legs may be got at with eaſe, in order to have them often rubbed in the day

---

workmen, very ingenious in making ſeveral kinds of toys of wood, which are carried through all the fairs of Germany, and from thence through all Europe. Theſe toys are called Nurembergs; and they have ſo great a ſale, that it even exceeds deſcription. This employment affords a livelihood to the greateſt part of the inhabitants of the city; and they make a very conſiderable profit from this traffic.

(c) Of theſe 42 members, there are only 34 choſen from the patrician families; the other eight are taken from among the burghers, and make in a manner a ſmall ſeparate body.

(d) This ſecret council is compoſed of ſeven principal chiefs of the republic, and for that reaſon is called *ſeptemvirate*. It determines the moſt important affairs; and is the depoſitory of the precious ſtones of the empire, of the imperial crown, the enſigns, ſeals, and keys of the city.

Nurſing.

day with a warm hand or flannel, and in particular the inſide of them.

Rubbing a child all over takes off ſcurf, and makes the blood circulate. The one breaſt ſhould be rubbed with the hands one way, and the other the other way, night and morning at leaſt.

The ankle bones and inſide of the knees ſhould be rubbed twice a day; this will ſtrengthen thoſe parts, and make the child ſtretch its knees and keep them flat, which is the foundation of an erect and graceful perſon.

A nurſe ought to keep a child as little in her arms as poſſible, leſt the legs ſhould be cramped, and the toes turned inwards. Let her always keep the child's legs looſe. The oftener the poſture is changed, the better.

Toſſing a child about, and exerciſing it in the open air in fine weather, is of the greateſt ſervice. In cities, children are not to be kept in hot rooms, but to have as much air as poſſible.

Want of exerciſe is the cauſe of large heads, weak and knotted joints, a contracted breaſt, w [illegible] ſions coughs and ſtuffed lungs, an ill [illegible] and waddling gait, beſides a numerous train [illegible] ills.

The child's fleſh is to be kept perfectly clean, by conſtantly waſhing its limbs and likewiſe its neck and ears; beginning with warm water, till by degrees it will not only bear, but like to be waſhed with cold.

Riſing early in the morning is good for all children, provided they awake of themſelves, which they generally do: but they are never to be waked out of their ſleep, and as ſoon as poſſible to be brought to regular ſleeps in the day.

When laid in bed or cradle, their legs are always to be laid ſtraight.

Children, till they are two or three years old, muſt never be ſuffered to walk long enough at a time to be weary.

Girls might be trained to the proper management of children, if a premium were given in free ſchools, workhouſes, &c. to thoſe that brought up the fineſt child to one year old.

If the mother cannot ſuckle the child, get a wholeſome cheerful woman, with young milk, who has been uſed to tend young children. After the firſt ſix months, ſmall broths, and innocent foods of any kind, may do as well as living wholly upon milk.

A principal thing to be always attended to is, to give young children conſtant exerciſe, and to keep them in a proper poſture.

With regard to the child's dreſs in the day, let it be a ſhirt; a petticoat of fine flannel, two or three inches longer than the child's feet, with a dimity top (commonly called a *bodice coat*), to tie behind; over that a ſurcingle made of fine buckram, two inches broad, covered over with ſatin or fine ticken, with a ribbon faſtened to it to tie it on, which anſwers every purpoſe of ſtays, and has none of their inconveniences. Over this put a robe, or a ſlip and frock, or whatever you like beſt; provided it is faſtened behind, and not much longer than the child's feet, that their motions may be ſtrictly obſerved.

Two caps are to be put on the head, till the child has got moſt of its teeth.

Nuſance ‖ Nutcracker.

The child's dreſs for the night may be a ſhirt, a blanket to tie on, and a thin gown to tie over the blanket.

NUSANCE, or Nuisance, in law, a thing done to the annoyance of another.

Nuiſances are either public or private.—A public nuiſance is an offence againſt the public in general, either by doing what tends to the annoyance of all the king's ſubjects, or by neglecting to do what the common good requires: in which caſe, all annoyances and injuries to ſtreets, highways, bridges, and large rivers, as alſo diſorderly alehouſes, bawdy-houſes, gaming houſes, ſtages for rope-dancers, &c. are held to be common nuiſances.—A private nuiſance is, when only one perſon or family is annoyed by the doing of any thing; as where a perſon ſtops up the light of another's houſe, or builds in ſuch a manner that the rain falls from his houſe upon his neighbour's.

NUT, among botaniſts, denotes a pericarpium of an extraordinary hardneſs, encloſing a kernel or ſeed.

NUTATION, in aſtronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former poſition.

NUTCRACKER. See Corvus, N° 8.

Plate cccxlvii.

"This bird (ſays Buffon) is diſtinguiſhed from the jays and magpies by the ſhape of its bill, which is ſtraighter, blunter, and compoſed of two unequal pieces. Its inſtinct is alſo different; for it prefers the reſidence of high mountains, and its diſpoſition is not ſo much tinctured with cunning and ſuſpicion."

They live upon hazel nuts, acorns, wild berries, the kernels of pine tops, and even on inſects.

"Beſides the brilliancy of the plumage, the nutcracker is remarkable for the triangular white ſpots which are ſpread over its whole body, except the head. Theſe ſpots are ſmaller on the upper part, and broader on the breaſt; their effect is the greater, as they are contraſted with the brown ground.

"Theſe birds are moſt attached, as I have obſerved above, to mountainous ſituations. They are common in Auvergne, Savoy, Lorraine, Franche-Compté, Switzerland, the Bergamaſque, in Auſtria, in the mountains which are covered with foreſts of pines. They alſo occur in Sweden, though only in the ſouthern parts of that country. The people in Germany call them Turkey birds, Italian birds, African birds, which language means no more than that they are foreign.

"Though the nutcrackers are not birds of paſſage, they fly ſometimes from the mountains to the plains. Friſch ſays, that flocks of them are often obſerved to accompany other birds into different parts of Germany, eſpecially where there are pine foreſts. But in 1754, great flights of them entered France, particularly Burgundy, where there are few pines; they were ſo fatigued on their arrival, that they ſuffered themſelves to be caught by the hand.

"We cannot find in writers of natural hiſtory any details with regard to their laying, their incubation, the training of their young, the duration of their life, &

&c. for they haunt inacceſſible ſpots, where they enjoy undiſturbed ſafety and felicity."

NUTHATCH, in ornithology. See SITTA, its generic name. In this place we ſhall only extract from Buffon an account of two ſpecies of foreign birds related to the nuthatch.

1. *The great hook-billed nuthatch.*—"It is the largeſt of the known nuthatches: its bill, though pretty ſtraight, is inflated at the middle, and a little hooked at the end; the noſtrils are round; the quills of the tail and of the wings edged with orange on a brown ground; the throat white; the head and back gray; the under ſide of the body whitiſh. Such are the principal properties of the bird. It was obſerved by Sloane in Jamaica.

"Its total length is about ſeven inches and a half; the bill is eight lines and one third; the upper mandible a little protuberant near the middle; the mid toe, eight lines and one third; the alar extent, eleven inches and a quarter; the tail about twenty-three lines."

Plate CCCXLVII.

2. *The ſpotted* or *Surinam nuthatch.*—This is another American nuthatch, with a hooked bill; but differs from the preceding in ſize, plumage, and climate: it inhabits Dutch Guiana.

"The upper ſide of the head and of the body is of a dull aſh colour; the ſuperior coverts of the wings of the ſame colour, but terminated with white; the throat white; the breaſt and all the under ſide of the body cinereous, and more dilute than the upper ſide, with white ſtreaks ſcattered on the breaſt and ſides, which forms a ſort of ſpeckling; the bill and legs brown.

"Total length, about ſix inches; the bill, an inch; the *tarſus*, ſeven lines and a half; the mid toe, eight or nine lines, and longer than the hind toe, whoſe nail is the ſtrongeſt; the tail, about eighteen lines, conſiſting of twelve nearly equal quills, and exceeds the wings thirteen or fourteen lines."

Plates CCCXXXIV. and CCCXXXV.

NUTMEG. See MYRISTICA, its generic name. The tree which produces this fruit, was formerly thought to grow only in the Banda iſlands. It is now paſt a doubt, however, that it grows in the Iſle of France and in all or moſt of the iſles of the South ſeas. It ſeems a little remarkable that this trade, which is certainly a lucrative one, ſhould have been ſo long monopolized by the Dutch. Their cunning and deſire to retain it in their own hands ſeems to account for the idea that ſo generally prevailed formerly that it grew only in their ſettlements. It was reported as early as the year 1751, upon what appeared at that time to be good grounds, that it was likely to be produced in the Weſt Indies. An Engliſh ſailor ſaid he had ſeen ſome trees in Jamaica, and the governor on inquiry found it ſo, and that they agreed exactly with the deſcription given of thoſe in the Spice Iſlands in the Eaſt Indies. This account, which was given in the Gentleman's Magazine for January 1751, we have never ſeen confirmed; and therefore we ſuppoſe that the expectations formed were either fruſtrated or premature: however, it is certain, as we have obſerved under the generic name, that a wild ſpecies of it grows at Tobego. To avoid repetition, or the appearance of prolixity, we muſt refer thoſe who wiſh for farther information reſpecting the trade in this article to M. P. Sonnerat's account of a voyage to the Spice Iſlands and New Guinea, which was printed at Paris in 1775, and tranſlated into Engliſh and printed at Bury St Edmund's in 1781, &c. and to Bougainville's voyage, and Dr Hawkeſworth's compilation of Engliſh voyages.

It will not, however, we truſt, be deemed improper, nor beſide our purpoſe, if we lay before our readers the following account of the dangerous conſequences of uſing this article to exceſs. It was given by Dr Jacob [illegible], publiſhed in the Gentleman's Magazine for [illegible].

"A gentleman of Lower Sileſia, about thirty-ſix years old, of a good conſtitution, and who enjoyed a good [illegible] of health, having felt, during ſome days, ſome [illegible], took it in his head, by way of remedy, to eat four nutmegs, which weighed all together two ounces, and he drank, in eating them, ſome glaſſes of [illegible], which he had no ſooner done, but he was ſeized with a great heat, a violent pain in the head, a vertigo, [illegible], and was inſtantly deprived of the uſe of ſight, ſpeech, and of all his ſenſes. He was put to bed, where he remained two days and two nights; his body was oppreſſed with laſſitude, always drowſy, yet without being able to ſleep. The third day he was in that lethargic ſtate, which is called a *coma vigil*, with a weak and intermitting pulſe. Cephalic remedies, cordials, and among others the ſpirit of cephalic vitriol, and the eſſence of caſtoreum, were adminiſtered in good ſpirit of ſal ammoniac. The fourth day he recovered a little, but had abſolutely loſt his memory, ſo as not to remember the leaſt thing he had done in his life. A continued fever then came on, accompanied by an obſtinate watchfulneſs; a palpitation of the heart ſeemed to be the forerunner of other ſymptoms, and he was finally ſtruck with a palſy in all his limbs.

"At the expiration of eight days, he recovered the uſe of reaſon, and ſaid, that during the firſt four days of his illneſs, he ſeemed to himſelf to have conſtantly a thick veil before his eyes, and that a great number of ſparks and flaſhes continually iſſued from it. All the bad ſymptoms of this malady yielded at laſt ſucceſſively to the continued uſe of remedies ſuited to his condition; and in three months time he was perfectly recovered, but he was particularly indebted for his cure to mercurial and ammoniacal remedies.

"According to chemical principles, it might perhaps be ſaid, that the aromatic and oily ſalt contained in nutmeg, of which this patient had taken too large a doſe, had immediately excited ſo great an agitation in the humours, and ſo rapid a motion in the animal ſpirits, as in ſome meaſure to partake of the nature of fire, and that a viſcid and narcotic ſulphur, which reſides likewiſe in the nutmeg, though in a leſs ſenſible manner, being carried at the ſame time into the maſs of blood, by ſuddenly fixing the animal ſpirits, and intercepting their courſe in the nerves, had afterwards cauſed the ſtupor in the limbs, the aphony, and the palſy. But I leave others to explain theſe phenomena; my only view, by communicating this obſervation, being to ſhow that the immoderate uſe of nutmeg may be attended with very great danger."

NUTRITION, in the animal economy, is the repairing the continual loſs which the different parts of the body undergo. The motion of the parts of the body, the friction of theſe parts with each other, and eſpecially the action of the air, would deſtroy the body entirely, if the loſs was not repaired by a proper diet, containing nutritive juices; which being digeſted in the ſtomach, and afterwards converted into chyle, mix with the blood, and are diſtributed through the whole body for its nutrition.

In young perſons, the nutritive juices not only ſerve to repair the parts that are damaged, but alſo to increaſe them, which is called *growth*.

In grown perſons, the cuticle is everywhere conſtantly deſquamating, and again renewing; and in the ſame manner the parts rubbed off, or otherwiſe ſeparated from the fleſhy parts of the body, are then ſupplied with new fleſh; a wound [illegible] ciated perſon grows plump and fat.

Buffon, in order to account for nutrition, ſuppoſes the body of an animal or vegetable to be a kind of mould, in which the matter neceſſary to its nutrition is modelled and aſſimilated to the whole. But (continues he) of what nature is this matter which an animal or vegetable aſſimilates to its own ſubſtance? What power is it that communicates to this matter the activity and motion neceſſary to penetrate this mould? and, if ſuch a force exiſt, would it not be by a ſimilar force that the internal mould itſelf might be reproduced?

As to the firſt queſtion, he ſuppoſes that there exiſts in nature an infinite number of living organical parts, and that all organized bodies conſiſt of ſuch organical parts; that their production coſts nature nothing, ſince their exiſtence is conſtant and invariable; ſo that the matter which the animal or vegetable aſſimilates to its ſubſtance, is an organical matter of the ſame nature with that of the animal or vegetable, which conſequently may augment its volume without changing its form or altering the quality of the ſubſtance in the mould.

As to the ſecond queſtion: There exiſt (ſays he) in nature certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the moſt intimate parts, and penetrate them throughout, and which can never fall under the obſervation of our ſenſes.

And as to the third queſtion, he anſwers, that the internal mould itſelf is reproduced, not only by a ſimilar power, but it is plain that it is the very ſame power that cauſes the unfolding and reproduction thereof: for it is ſufficient (proceeds he), that in an organized body that unfolds itſelf, there be ſome part ſimilar to the whole, in order that this part may one day become itſelf an organized body, altogether like that of which it is actually a part.

NUX MOSCHATA. See MYRISTICA and NUTMEG.

Nux Piſtachia. See PISTACHIA.

Nux Vomica, a flat, compreſſed, round fruit, about the breadth of a ſhilling, brought from the Eaſt Indies. It is found to be a certain poiſon for dogs, cats, &c. and it is not to be doubted that it would alſo prove fatal to mankind. Its ſurface is not much corrugated; and its texture is firm like horn, and of a pale grayiſh-brown colour. It is ſaid to be uſed as a ſpecific againſt the bite of a ſpecies of water ſnake. It is conſiderably bitter and deleterious; but has been uſed in doſes from five to ten grains twice a-day or ſo, in intermittents, particularly obſtinate quartans, and in contagious dyſentery. The *ſtrychnus Ignatii* is a tree of the ſame kind producing gourd-like fruit, the ſeeds of which are improperly called St Ignatius's beans. Theſe, as alſo the woods or roots of ſome ſuch trees, called *lignum colobrinum* or *ſnakewood*, are very narcotic bitters like the nux vomica.

NUYTS (Peter), a native of Holland, and a leading character in that extraordinary tranſaction which happened between the Japaneſe and the Dutch about the year 1628. In 1627 Nuyts arrived in Batavia from Holland, and was in the ſame year appointed ambaſſador to the emperor of Japan by the governor and council of Batavia.

He repaired to that empire in 1628; and being a man of a haughty diſpoſition, and extremely vain, he believed it practicable to paſs upon the natives for an ambaſſador from the king of Holland. Upon his aſſuming this title he was much more honourably received, careſſed, and reſpected, than former miniſters had been. But he was ſoon detected, reprimanded, and reproached in the ſevereſt manner, ſent back to the port, and ordered to return to Batavia with all the circumſtances of diſgrace imaginable; notwithſtanding which, his intereſt was ſo great, that, inſtead of being puniſhed as he deſerved, he was immediately afterwards promoted to the government of the iſland of Formoſa, of which he took poſſeſſion the year following.

He entered upon the adminiſtration of affairs in that iſland with the ſame diſpoſition that he had ſhown while ambaſſador, and with the moſt implacable reſentment againſt the Japaneſe, neither was it long before an opportunity offered, as he thought, of revenging himſelf to the full. Two large Japaneſe ſhips, with upwards of five hundred men on board, came into the port; upon which he took it into his head to diſarm and unrig them, in the ſame manner as the Dutch veſſels are treated at Japan. The Japaneſe did all they could to defend themſelves from this ill uſage; but at laſt, for want of water, they were forced to ſubmit. Governor Nuyts went ſtill further. When they had finiſhed their affairs at Formoſa, and were deſirous of proceeding, according to their inſtructions, to China, he put them off with fair words and fine promiſes till the monſoon was over. They began then to be very impatient, and deſired to have their cannon and ſails reſtored, that they might return home; but the governor had recourſe to new artifices, and, by a ſeries of falſe promiſes, endeavoured to hinder them from making uſe of the ſeaſon proper for that voyage.

The Japaneſe, however, ſoon perceived his deſign; and at length, by a bold attempt, accompliſhed what by fair means and humble entreaty they could not obtain; for, by a daring and well concerted effort, they took him priſoner, and made him and one of the council ſign a treaty for ſecuring their liberty, free departure, and indemnity, which was afterwards ratified by the whole council. Nuyts was firſt confined in Batavia, and afterwards delivered up to the Japaneſe, notwithſtanding the moſt earneſt entreaties on his part to be tried, and even to ſuffer any kind of death where he was, rather than to be ſent to Japan. He was ſent thither, however, in 1634. He was ſubmitted to the mercy or diſcretion of the emperor; and the conſequence was, that, though impriſoned, he was well uſed, and could go anywhere, provided his guards were with him, which was more than he could poſſibly have expected. He now looked for nothing but the continuance of his confinement for life. On a particular occaſion, however, i. e. at the funeral of the emperor's father, at the requeſt of the Dutch he was ſet free, and returned again to Batavia, to the ſurpriſe of that people, who, however, adopted ever after a very different conduct with reſpect to the Japaneſe.

NUZZER, or NUZZERANAH; a preſent or offering from an inferior to a ſuperior. In Hindoſtan no man ever approaches his ſuperior for the firſt time on buſineſs without an offering of at leaſt a gold or ſilver rupee in his right hand; which if not taken is a mark of diſfavour. Nuzzeranah is alſo uſed for the ſum paid to the government as an acknowledgment for a grant of lands or any public office.

NYCHTHEMERON, among the ancients, ſignified the whole natural day, or day and night, conſiſting of 24 hours, or 24 equal parts. This way of conſidering the day was particularly adopted by the Jews, and ſeems to owe its origin to that expreſſion of Moſes, in the firſt chapter of Geneſis, "the evening and the morning were the firſt day."—Before the Jews had introduced the Greek language into their diſcourſe, they uſed to ſignify this ſpace of time by the ſimple expreſſion of a night and a day.

It is proper here to obſerve, that all the eaſtern countries reckoned any part of a day of 24 hours for a whole day; and ſay a thing that was done on the third or ſeventh day, &c. from that laſt mentioned, was done after three or ſeven days. And the Hebrews, having no word which exactly anſwers to the Greek *Νυχημερον*, ſignifying "a natural day of 24 hours," uſe *night and day*, or *day and night*, for it. So that to ſay a thing happened after three days and three nights, was, with them, the ſame as to ſay it happened after three days, or on the third day. This, being remembered, will explain what is meant by "the Son of Man's being three days and three nights in the heart of the earth."

NYCTALOPIA. See MEDICINE, N° 361.

NYCTANTHES, ARABIAN JASMINE: A genus of the monogynia order, belonging to the diandria claſs of plants; and in the natural method ranking with the 44th order, *Sapiariæ*. The corolla and calyx are octofid; the perianthium dicoccous. There are five ſpecies: the moſt remarkable of which are, 1. The arbor triſtis, or ſorrowful tree. This tree, or ſhrub, the *pariatacu* of the Bramins, grows naturally in ſandy places in India, particularly in the iſlands of Ceylon and Java, where it is produced in great abundance, and attains the height of 18 or 20 feet. It riſes with a four-cornered ſtem, bearing leaves that are oval, and taper to a point. They ſtand oppoſite, on ſhort footſtalks; are of a ſhining browniſh green on the upper ſide, a more vivid green on the under, and of a taſte that is aſtringent and ſomewhat bitter. From the middle rib, on the under ſurface of the leaves, proceed on both ſides a number of coſtulæ, or ſmaller ribs, which run nearly to the margin, and mark the ſurface with the impreſſion of their arched furrows. The flowers, which are white and highly odoriferous, having a ſweet delectable ſmell emulating the beſt honey, conſiſt of one petal deeply divided into eight parts, which are narrower towards the ſtalk, and dilated towards the ſummit. They ſtand upon footſtalks, which emerge from the origin of the leaves; are rigid, obliquely raiſed towards the top, grow oppoſite in pairs, and are divided into three ſhort leſſer branches, which each ſupports five flowers placed cloſe together, without partial footſtalks. The fruit is dry, capſular, membranaceous, and compreſſed.

It is generally aſſerted of this plant, that the flowers open in the evening, and fall off the ſucceeding day. Fabricius and Paludanus, however, reſtrict the aſſertion, by affirming, from actual obſervation, that this effect is found to take place only in ſuch flowers as are immediately under the influence of the ſolar rays. Grimmius remarks in his *Laboratorium Ceylonicum*, that the flowers of this tree afford a fragrant water, which is cordial, refreſhing, and frequently employed with ſucceſs in inflammations of the eyes. The tube of the [illegible], when dried, has the ſmell of ſaffron; and, being pounded and mixed with ſanders wood, is uſed by the natives of the Malabar coaſt for imparting a grateful fragrancy to their bodies, which they rub or anoint with the mixture.

2. The ſambac, noted, like the other ſpecies, for the fragrancy of its flowers, is a native likewiſe of India; and is cultivated in our ſtoves, where it generally riſes with a twining ſtem to the height of 18 or 20 feet. The leaves are oppoſite, ſimple, and entire; but in different parts of the plant aſſume different forms: the lower leaves being heart-ſhaped and blunt; the upper, oval and ſharp. The flowers are white, inexpreſſibly fragrant, and generally appear with us in the warm ſummer months. Strong loam is its proper ſoil. There is a variety of this ſpecies with a double flower, which is much larger and more fragrant than the former.

NYCTASTRATEGI, among the ancients, were officers appointed to prevent fires in the night, or to give alarm and call aſſiſtance when a fire broke out. At Rome they had the command of the watch, and were called *nocturni triumviri*, from their office and number.

NYCTICORAX, in ornithology, the night raven; a ſpecies of ARDEA.

NYE (Philip), an Engliſh nonconformiſt, a native of Suſſex, deſcended of a genteel family there, was born about 1596. After a proper foundation at the grammar ſchool, he was ſent to Oxford, and entered a commoner of Brazen Noſe college in 1615, whence he removed in a little time to Magdalen hall, under a puritanical tutor. He took the degrees in arts in 1619 and 1622, about which time he entered into holy orders, and was, ſome time in 1620, curate of St Michael's church in Cornhill, London. Reſolving, however, to reject the conſtitution of the church of England, he became obnoxious to all the cenſures of the epiſcopal court; to avoid which, he went, with others of his perſuaſion, to Holland, in 1633. He continued for the moſt part at Arnheim, in Guelderland, till 1640; when, the power of the parliament beginning to prevail over the king, he returned home, and was ſoon after made miniſter of Kimbolton in Huntingdonſhire, by Edward lord Kimbolton, then earl of Mancheſter. In 1643, he was appointed one of the

Nye.

aſſembly of divines, and became a great champion of the Preſbyterians, and a zealous aſſertor of the ſolemn league and covenant; and, having married the daughter of Stephen Marſhall, was ſent with his father-in-law into Scotland the ſame year, to expedite the taking of their covenant. Accordingly he harangued that people, in ſome ſpeeches on the occaſion; in which he told them, among other things, that they were entered into ſuch a covenant and league as would never be forgotten by them and their poſterity, and both would have occaſion to remember it with joy; that it was ſuch an oath, for matter, perſons, and other circumſtances, that the like had not been in any age, ſufficiently warranted both by human and divine ſtory: for, as God did ſwear for the ſalvation of men and kingdoms, ſo kingdoms muſt now ſwear for the preſervation and ſalvation of kingdoms, to eſtabliſh a Saviour Jeſus Chriſt in England, &c. After his return, both houſes of parliament took the covenant the ſame year; at which time he preached a ſermon in defence of it, ſhowing its warrant from Scriptures, and was rewarded for his good ſervice with the rectory of Acton near London, in the room of Dr Daniel Featly, who was ejected from it. Not long after however, Nye began to diſlike the proceedings of the ſaid aſſembly of divines, and diſſented from them, oppoſing the diſcipline intended to be ſettled by them; and, cloſing with the Independents when they became the reigning faction, he paid his court to the grandees of the army, who often made uſe of his council. In December 1647 he was ſent by them, with Stephen Marſhall, to the king at Cariſbrook caſtle, in the iſle of Wight, in attendance upon the commiſſioners then appointed to carry the four dethroning votes, as they are now called, viz. 1. To acknowledge the war raiſed againſt him to be juſt; 2. To aboliſh epiſcopacy; 3. To ſettle the power of the militia in perſons nominated by the two houſes; 4. To ſacrifice all thoſe that had adhered to him: for which ſervice they were rewarded with no leſs than 500l. a piece. Nye was alſo employed about that time by the ſame maſters to get ſubſcriptions from the apprentices in London, &c. againſt a perſonal treaty with the king, while the citizens of that metropolis were petitioning for one. April the next year he was employed, as well as Marſhall and Joſeph Caryl, by the Independents, to invite the ſecured and ſecluded members to ſit in the houſe again, but without ſucceſs. In 1653 he was appointed one of the triers for the approbation of public preachers; in which office he not only procured his ſon to be clerk, but, with the aſſiſtance of his father-in-law, obtained for himſelf a living of 400l. a year. In 1654, he was joined with Dr Lazarus Seaman, Samuel Clark, Richard Vines, Obadiah Sedgwick, Joſeph Caryl, &c. as an aſſiſtant to the commiſſioners appointed by parliament to eject ſuch as were then called ſcandalous and ignorant miniſters and ſchoolmaſters in the city of London. After Charles II's reſtoration in 1660, it was debated by the healing parliament, for ſeveral hours together, whether he and John Goodwin ſhould be excepted for life; but the reſult was, that if Philip Nye, clerk, ſhould after the 1ſt of September, in the ſame year 1660, accept or exerciſe any office, eccleſiaſtical, civil, or military, he ſhould, to all intents and purpoſes in law, ſtand as if he had been totally excepted for life. November 1662 he was vehemently ſuſpected to be engaged in Tongue's plot: but the ſuſpicion was never proved. He died in the pariſh of St Michael's, Cornhill, London, on Sept. 27. 1672, and was buried in the upper vault of the ſaid church. Wood ſays he was a dangerous and ſeditious perſon, a politic pulpit-driver of independency, an inſatiable eſurient after riches, and what not, to raiſe a family, and to heap up wealth.

Nyland, Nyl-Ghau.

NYLAND, a province of Finland in Sweden, lying on the gulf of Finland, to the weſt of the province of Carelia.

Plate CCCXLVII.

NYL-GHAU, in zoology, of the genus *Bos*, a native of the interior parts of India. "It ſeems (ſays Bewick in his Hiſt. of Quadr.) to be of a middle nature between the cow and the deer, and carries the appearance of both in its form. In ſize, it is as much ſmaller than the one, as it is larger than the other; its body, horns, and tail, are not unlike thoſe of a bull; and the head, neck, and legs, are ſimilar to thoſe of a deer. The colour in general is aſh or gray, from a mixture of black hairs and white; all along the ridge or edge of the neck, the hair is blacker, longer, and more erect, making a ſhort, thin, and upright mane, reaching down to the hump. Its horns are ſeven inches long, ſix inches round at the root, tapering by degrees, and terminating in a blunt point: the ears are large and beautiful, ſeven inches in length, and ſpread to a conſiderable breadth; they are white on the edge and on the inſide, except where two black bands mark the hollow of the ear with a zebra-like variety. The height of this animal at the ſhoulder is four feet one inch; behind the loins, it only meaſures four feet.

"The female differs conſiderably from the male both in height and thickneſs, being much ſmaller; in ſhape and colour very much reſembling a deer; and has no horns. She has four nipples, and is ſuppoſed to go nine months with young. She commonly has one at a birth, but ſometimes two.

"Several of this ſpecies were brought to this country in the year 1767, which continued to breed annually for ſome years after. Dr Hunter, who had one of them in his cuſtody for ſome time, deſcribes it as a harmleſs and gentle animal; that it ſeemed pleaſed with every kind of familiarity, always licked the hand that either ſtroked or fed it, and never once attempted to uſe its horns offenſively. It ſeemed to have much dependence on its organs of ſmell, and ſnuffed keenly whenever any perſon came in ſight: It did ſo likewiſe when food or drink was brought to it; and would not taſte the bread which was offered, if the hand that preſented it happened to ſmell of turpentine.

"Its manner of fighting is remarkable, and is deſcribed thus. Two of the males at Lord Clive's, being put into an encloſure, were obſerved, while they were at ſome diſtance from each other, to prepare for the attack, by falling down upon their knees; they then ſhuffled towards each other, keeping ſtill upon their knees; and at the diſtance of a few yards they made a ſpring, and darted againſt each other with great force.

"The following anecdote will ſerve to ſhow, that during the rutting ſeaſon theſe animals are fierce and vicious, and not to be depended upon. A labouring man, without knowing that the animal was near him, went up to the outſide of the encloſure; the nyl-ghau, with the quickneſs of lightning darted againſt the wood work with ſuch violence, that he broke it to pieces, and broke off one of his horns cloſe to the root. The death of the animal, which happened ſoon after, was ſuppoſed to be owing to the injury he ſuſtained by the blow.

"Bernier ſays, that it is the favourite amuſement of the Mogul emperor to hunt the nyl-ghau; and that he kills them in great numbers, and diſtributes quarters of them to his omrahs; which ſhows that they are eſteemed good and delicious food.

"The nyl-ghau is frequently brought from the interior parts of Aſia, as a rare and valuable preſent to the nabobs and other great men at our ſettlements in India.

"It remains to be conſidered, whether this rare animal might not be propagated with ſucceſs in this country. That it will breed here is evident from experience; and if it ſhould prove docile enough to be eaſily trained to labour, its great ſwiftneſs and conſiderable ſtrength might be applied to the moſt valuable purpoſes."

NYMPH, in mythology, an appellation given to certain inferior goddeſſes, inhabiting the mountains, woods, waters, &c. ſaid to be the daughters of Oceanus and Tethys. All the univerſe was repreſented as full of theſe nymphs, who are diſtinguiſhed into ſeveral ranks or claſſes. The general diviſion of them is into celeſtial and terreſtrial; the former of them were called *uraniæ*, and were ſuppoſed to be intelligences that governed the heavenly bodies or ſpheres. The terreſtrial nymphs, called *epigeiæ*, preſided over the ſeveral parts of the inferior world; and were divided into thoſe of the water and thoſe of the earth. The nymphs of the water were the *oceanitides*, or nymphs of the ocean; the *nereids*, the nymphs of the ſea; the *naiads* and *ephydriades*, the nymphs of the fountains; and the *limniades*, the nymphs of the lakes. The nymphs of the earth were the *oreades*, or nymphs of the mountains; the *napææ*, nymphs of the meadows: and the *dryads* and *hamadryads*, who were nymphs of the foreſts and groves. Beſides theſe, we meet with nymphs who took their names from particular countries, rivers, &c. as the *cithæroniades*, ſo called from Mount Cithæron in Bœotia: the *dodonides*, from Dodona; *tiberiades*, from the Tiber, &c.—Goats were ſometimes ſacrificed to the nymphs; but their conſtant offerings were milk, oil, honey, and wine.

We have the following account of nymphs in Chandler's Greece. "They were ſuppoſed to enjoy longevity, but not to be immortal. They were believed to delight in ſprings and fountains. They are deſcribed as ſleepleſs, and as dreaded by the country people. They were ſuſceptible of paſſion. The Argonauts, it is related, landing on the ſhore of the Propontis to dine in their way to Colchos, ſent Hylas, a boy, for water, who diſcovered a lonely fountain, in which the nymphs Eunica, Malis, and Nycheia were preparing to dance; and theſe ſeeing him were enamoured, and, ſeizing him by the hand as he was filling his vaſe, pulled him in. The deities, their copartners in the cave, are ſuch as preſided with them over rural and paſtoral affairs.

"The old Athenians were ever ready to cry out, A god! or a goddeſs! The tyrant Piſiſtratus entered the city in a chariot with a tall woman dreſſed in armour to reſemble Minerva, and regained the Acropolis, which he had been forced to abandon, by this ſtratagem; the people worſhipping, and believing her to be the deity whom ſhe repreſented. The nymphs, it was the popular perſuaſion, occaſionally appeared; and nympholepſy is characterized as a frenzy, which aroſe from having beheld them. Superſtition diſpoſed the mind to adopt deluſion for reality, and gave to a fancied viſion the efficacy of full conviction. The foundation was perhaps no more than an indirect, partial, or obſcure view of ſome harmleſs girl, which had approached the fountain on a like errand with Hylas, or was retiring after ſhe had filled her earthen pitcher.

"Among the ſacred caves on record, one on Mount Ida in Crete was the property of Jupiter, and one by Lebadea in Bœotia of Trophonius. Both theſe were oracular, and the latter bore ſome reſemblance to that we have deſcribed. It was formed by art, and the mouth ſurrounded with a wall. The deſcent to the landing place was by a light and narrow ladder, occaſionally applied and removed. It was ſituated on a mountain above a grove, and they related, that a ſwarm of bees conducted the perſon by whom it was firſt diſcovered. But the common owners of caves were the nymphs, and theſe were ſometimes local. On Cithæron in Bœotia, many of the inhabitants were poſſeſſed by nymphs called *Sphragitides*, whoſe cave, once alſo oracular, was on a ſummit of the mountain. Their dwellings had generally a well or ſpring of water; the former often a collection of moiſture condenſed or exuding from the roof and ſides; and this, in many inſtances, being pregnant with ſtony particles, concreted, and marked its paſſage by incruſtation, the ground work in all ages and countries of idle tales framed or adopted by ſuperſtitious and credulous people.

"A cave in Paphlagonia was ſacred to the nymphs who inhabited the mountains about Heraclea. It was long and wide, and pervaded by cold water, clear as cryſtal. There alſo were ſeen bowls of ſtone, and nymphs and their webs and diſtaffs, and curious work, exciting admiration. The poet who has deſcribed this grotto, deſerves not to be regarded, as ſervilely copying Homer; he may juſtly claim to rank as an original topographer.

"The piety of Archidamus furniſhed a retreat for the nymphs, where they might find ſhelter and proviſion, if diſtreſſed; whether the ſun parched up their trees, or Jupiter enthroned in clouds upon the mountain top ſeared them with his red lightning and terrible thunder, pouring down a deluge of rain, or brightening the ſummits with his ſnow."

NYMPH, among naturaliſts, that ſtate of winged inſects between their living in the form of a worm and their appearing in the winged or moſt perfect ſtate.

The eggs of inſects are firſt hatched into a kind of worms or maggots; which afterwards paſs into the nymph ſtate, ſurrounded with ſhells or caſes of their own ſkins; ſo that, in reality, theſe nymphs are only the embryo inſects, wrapped up in this covering; from whence they at laſt get looſe, though not without great difficulty.

During this nymph ſtate the creature loſes its motion. Swammerdam calls it *nympha aurelia*, or ſimply *aurelia*; and others give it the name of *chryſalis*, a term of the like import. See the article CHRYSALIS.

NYMPH-Bank, ſituated about 10 leagues off the coaſt of the county of Waterford, and province of Munſter in Ireland, is a great fiſhing place, and 11 leagues S. S. E. from the high head of Dungarvan. It abounds with cod, ling, ſkate, bream, whiting, and other fiſh; which was diſcovered by Mr Doyle, who on July 15. 1736 ſailed to it, in company with ſeven men, on board the Nymph, a ſmall veſſel of about 12 guns. This place is well adapted for a fiſhing company, the great public advantages of which muſt be very evident.

NYMPHÆ, in anatomy, two membranaceous parts, ſituated on each ſide the rima. They are of a red colour, and cavernous ſtructure, ſomewhat reſembling the wattles under a cock's throat. They are ſometimes ſmaller, ſometimes larger; and are continuous to the præputium of the clitoris, and joined to the anterior ſide of the labia.

NYMPHÆA, the WATER-
monogynia order, belonging to the
plants; and in the natural method
54th order, *Miſcellaneæ*. The corolla
the calyx tetraphyllous or pent
multilocular and truncated.
of which the moſt remarkable
and alba, or yellow and white [illegible] of which are natives of Britain, growing in lakes and ditches. Linnæus tells us, that ſwine are fond of the leaves and roots of the former; and that the ſmoke of it will drive away crickets and blattæ, or cockroaches, out of houſes.—The root of the ſecond has an aſtringent and bitter taſte, like thoſe of moſt aquatic plants that run deep into the mud. The Highlanders make a dye with it of a dark cheſnut colour. 3. The lotus, with heart-ſhaped toothed leaves, a plant thought to be peculiar to Egypt, is thus mentioned by Herodotus †: "When the river Nile is become full, and all the grounds round it are a perfect ſea, there grows a vaſt quantity of lilies, which the Egyptians call *lotus*, in the water. After they have cut them, they dry them in the ſun, then having parched the ſeed within the lotus, which is moſt like the poppy, they make bread of it, baking it with fire. The root alſo of the lotus is eatable, eaſily becoming ſweet, being round, and of the ſize of an apple." M. Savary ‡ mentions it as growing in the rivulets and on the ſides of the lakes; and that there are two ſorts or varieties of the plant, the one with a white, the other with a bluiſh flower. "The calyx (he ſays) blows like a large tulip, and diffuſes a ſweet ſmell, reſembling that of the lily. The firſt ſpecies produces a round root like that of a potato, and the inhabitants of the banks of the lake Menzall feed upon it. The rivulets in the environs of Damietta are covered with this majeſtic flower, which riſes upwards of two feet above the water. 4. In the Eaſt and Weſt Indies grows a ſpecies of this plant, named *nelumbo* by the inhabitants of Ceylon. The leaves which reſt upon the ſurface of the water are ſmooth, undivided, perfectly round, thick, target ſhaped, and about one foot and a half in diameter. The footſtalk of the leaves is prickly, and inſerted, not into their baſe, or margin, as in moſt plants, but in the centre of the lower diſk or ſurface. From this centre, upon the upper ſurface, iſſue like rays, a great number of large ribs or nerves, which towards the circumference are divided and ſubdivided into a ſmall number of very minute parts. The flowers are large, fleſh coloured, and conſiſt of numerous petals, diſpoſed, as in the other ſpecies of water lily, in two or more rows. The ſeed veſſel is ſhaped like a top, being broad and circular above, narrow and almoſt pointed below. It is divided into ſeveral diſtinct cells, which form ſo many large round holes upon the ſurface of the fruit; each containing a ſingle ſeed.—With the flower of this plant, which is ſacred among the heathens, they adorn the altars of their temples: they paint their gods ſitting upon it; and make uſe of ſuch pictures to animate the minds of the pious on their deathbed, and to raiſe their affections to heaven. The ſtalks, which are uſed as a pot herb, are of a wonderful length. The root is very long, extends itſelf tranſverſely, is of the thickneſs of a man's arm, jointed and fibrous, with long intervals betwixt the joints. The fibres ſurround the joints in verticilli or whirls. 5. A ſpecies of nymphæa, called by the Chineſe *lien hoa* and *nenufar*, is highly extolled in that country for its excellent virtues, and ranked by their phyſicians among thoſe plants which are employed in the compoſition of *the liquor of immortality*. The ſeeds are there eaten as we eat filberds in Europe: they are more delicate when they are green, but harder of digeſtion; they are preſerved in many different ways with ſugar. The root of this plant is alſo admitted by the Chineſe to their tables: in whatever manner it be prepared, it is equally wholeſome. Great quantities of it are pickled with ſalt and vinegar, which they preſerve to eat with their rice. When reduced to powder, it makes excellent ſoup with water and milk. The leaves of the nenufar are much uſed for wrapping up fruits, fiſh, ſalt proviſions, &c. When dry, the Chineſe mix them with their ſmoking tobacco, to render it ſofter and milder.

The high veneration in which the *nymphæa lotos* was held by the Egyptians, is fully known; and at this hour it is equally venerated by the Hindoos. Sir William Jones, in ſpeaking of Brahma, Viſhnu, and Shiva, as emblematical repreſentations of the Deity, ſays,

"The firſt operations of theſe three powers are evidently deſcribed in the different Puranas by a number of allegories; and from them we may deduce the Ionian philoſophy of primæval water, the doctrine of the mundane egg, and the veneration paid to the nymphæa or lotos, which was anciently revered in Egypt, as it is at preſent in Hindoſtan, Thibet, and Nepal. The Thibetians are ſaid to embelliſh their temples and altars with it; and a native of Nepal made proſtrations before it on entering my ſtudy where the fine plant and beautiful flowers lay for examination."

NYMPHÆA (amongſt the ancients), doubtful what ſtructures they were, ſome take them to have been grottos, deriving their name from the ſtatues of the nymphs with which they were adorned, but that they were conſiderable works appears from their being executed by the emperors, (Ammian, Victor, Capitolinus) or by the city prefects. In an inſcription, the term is written *nymfium*. None of all theſe nymphæa has laſted down to our time. Some years ſince, indeed, a ſquare building of marble was diſcovered between Naples and Veſuvius, with only one entrance, and ſome ſteps that went down to it. On the right hand as

† *Euterpe*, c. 92.

‡ *Letters on Egypt*, Vol I.

you enter, towards the head, there is a fountain of the pureſt water; along which, by way of guard as it were, is laid a naked Arethuſa of the whiteſt marble; the bottom or ground is of variegated marble, and encompaſſed with a canal fed by the water from the fountain: the walls are ſet round with ſhells and pebbles of various colours; by the ſetting of which, as by ſo many ſtrokes in a picture, are expreſſed the 12 months of the year, and the four political virtues; alſo the rape of Proſerpine; Pan playing on his reed, and ſoothing his flock; beſides the repreſentations of nymphs ſwimming, ſailing, and wantoning on fiſhes, &c.

It ſeems pretty evident that the nymphæa were public baths; for at the ſame time that they were furniſhed with pleaſing grottos, they were alſo ſupplied with cooling ſtreams, by which they were rendered exceedingly delightful, and drew great numbers of people to frequent them. Silence ſeems to have been a [illegible]lar requiſite there, as appears by this inſcription, *Nymphis loci, bibe, lava, tace.* That building between Naples and Veſuvius mentioned above, was certainly one of theſe nymphæa.

NYMPHÆUM, (Plutarch); the name of a ſacred place, near Apollonia in Illyricum, ſending forth continually fire in detached ſtreams from a green valley and verdant meadows. Dio Caſſius adds, that the fire neither burns up nor parches the earth, but that herbs and trees grow and thrive near it, and therefore the place is called *nymphæum:* near which was an oracle of ſuch a nature, that the fire, to ſhow that the wiſh was granted, conſumed the frankincenſe thrown into it; but repelled it, in caſe the deſire was rejected. It was there that a ſleeping ſatyr was once caught and brought to Sylla as he returned from the Mithridatic war. This monſter had the ſame features as the poets aſcribe to the ſatyr. He was interrogated by Sylla and by his interpreters; but his articulations were unintelligible, and the Roman ſpurned from him a creature which ſeemed to partake of the nature of a beaſt more than that of a man.

Nymphæum, in antiquity, a public hall magnificently decorated, for entertainments, &c. and where thoſe who wanted convenience at home held their marriage feaſts; whence the name.

NYMPHIDIUS (Sabinus), a perſon of mean deſcent, but appointed by Nero colleague of Tigellinus in the command of the prætorian guards. About the time, however, that the German legions revolted from this deſpicable prince, he was alſo betrayed by Nymphidius and abandoned by his guards.

Nymphidius began now to entertain thoughts of ſeizing the ſovereignty himſelf. However, he did not immediately declare his ambitious views; but pretending to eſpouſe the cauſe of Galba, aſſured the guards that Nero was fled, and promiſed them ſuch ſums as neither Galba nor any other was able to diſcharge. This promiſe ſecured for the preſent the empire to Galba, occaſioned afterwards the loſs of it, and, finally, produced the deſtruction of Nymphidius and the guards themſelves. After Nero's death, however, and on the acknowledgment of Galba as emperor, he renewed his ambition; and having, by his immenſe largeſſes, gained the affections of the prætorian guards, and perſuading himſelf that Galba, by reaſon of his infirmities and old age, would never reach the capital, uſurped all the authority at Rome. Preſuming upon his intereſt, he obliged Tigellinus, who commanded, jointly with him, the prætorian guards, to reſign his commiſſion. He made ſeveral magnificent and expenſive entertainments, inviting ſuch as had been conſuls or had commanded armies, diſtributed large ſums among the people, and with ſhows and other diverſions, which he daily exhibited, gained ſo great an intereſt with all ranks, that he already looked upon himſelf as ſoverign. The ſenate, dreading his power, conferred extraordinary honours upon him, ſtyled him their *protector*, attended him when he appeared in public, and had recourſe to him for the confirmation of their decrees, as if he had been already inveſted with the ſovereign power. This baſe compliance [illegible] to ſuch a degree, that he uſurped, not [illegible] by degrees, but all at once, an abſolute [illegible]. He acted as ſovereign indeed, but he had [illegible] yet openly declared his deſign of ſeizing the [illegible] his power however was great, and he uſed [illegible] undermining Galba's power; he was, however, unſucceſsful, and the diſcloſure of his deſigns was much againſt him. Galba was again acknowledged and proclaimed; and he, notwithſtanding his artifices, detected and ſlain by the ſoldiers who were proclaiming Galba. See Nero.

NYON, a conſiderable town of Switzerland, in the canton of Bern, and capital of a bailiwick of the ſame name, with a caſtle. It ſtands delightfully upon the edge of the lake of Geneva, in the very point where it begins to widen, and in a moſt charming country commonly called *Pays de Vaud.* It was formerly called *Colonia Equeſtris Noiodunum;* and, as a proof of its antiquity, ſeveral Roman inſcriptions, and other ancient remains have been frequently diſcovered in the outſkirts of the town. E. Long. 5. 10. N. Lat. 46. 24.

NYSA, or Nyssa (anc. geog.), a town of Ethiopia, at the ſouth of Egypt. Some place it in Arabia. This city, with another of the ſame name in India, was ſacred to the god Bacchus, who was educated there by the nymphs of the place, and who received the name of *Dionyſus*, which ſeems to be compounded of Διος and Νυσα, the name of his father, and that of the place of his education. The god made this place the ſeat of his empire, and the capital of the conquered nations of the eaſt. According to ſome geographers, there were no leſs than ten places of this name. One of theſe was famous on the coaſt of Eubœa for its vines, which grew in ſuch an uncommon manner, that if a twig was planted in the ground in the morning, it immediately produced grapes which were full ripe in the evening. A city of Thrace: another ſeated on the top of Mount Parnaſſus, and ſacred to Bacchus.

NYSLOT, a ſtrong town of Ruſſia, in Livonia, with a caſtle; ſeated on the river Narva, among large marſhes. E. Long. 26. 55. N. Lat. 58. 46.

NYSSA, in botany: A genus of the order of diœcia, belonging to the polygamia claſs of plants; and in the natural method ranking under the 12th order, *Holoraceæ.* The hermaphrodite calyx is quinquepartite; there is no corolla; the ſtamina are five; there is one piſtil; the fruit a plum inferior. The male calyx is quinquepartite, no corolla, and ten ſtamina.

Nyſſa.

mina. There is only one ſpecies, the *nyſſa aquatica* or tupelo tree. It is a deciduous tree or ſhrub, a native of moiſt or watery places in America, and conſiſts of two varieties: 1. The entire-leaved; and, 2. The ſerrated-leaved tupelo.

Planting and Gardening.

The entire-leaved tupelo tree, in its native ſoil and climate, grows to near 20 feet high; in this country its ſize varies according to the nature of the ſoil or ſituation. In a moiſt rich earth, well ſheltered, it comes near to 20 feet; in others, that are leſs ſo, it makes ſlower progreſs, and in the end is proportionally lower. The branches are not very numerous, and it riſes with a regular trunk, at the top of which they generally grow. The leaves are of a lanceolated figure, and of a fine light green colour. They [illegible] points, and are very ornamental, of a thick[illegible]ence, ſoft, grow alternately on pretty long [illegible] and often retain their verdure late in the [illegible]. The flowers, which are not very ornamental, [illegible]duced from the ſides of the branches, growing [illegible] ſingly, ſometimes many together, on a [illegible] They are of a greeniſh colour; and, in the [illegible] where they naturally grow, are ſucceeded [illegible] encloſing oval, acute, furrowed nuts. [illegible] they ſeldom produce fruit.

The ſerrated-leaved tupelo tree grows uſually nearly 30 feet in height; and divides into branches near the top like the other. The leaves are oblong, pointed, of a light green colour, and come out without order on long footſtalks. The flowers come out from the wings of the leaves on long footſtalks. They are ſmall, of a greeniſh colour; and are ſucceeded by oval drupes, containing ſharp-pointed nuts, about the ſize of a French olive.

The propagation of theſe trees is from ſeeds, which come from America. As ſoon as they arrive, they ſhould be ſown in large pots of light ſandy earth an inch deep. The gardener (no plants come up the firſt ſpring), after this work is done, ſhould plunge his pots up to their rims in the natural ground; and if it be a moiſt place, it will be the better. Weeding muſt be obſerved during the ſummer; and a few furze-buſhes ſhould be pricked round the pots in November, which will prevent the ground from freezing, and forward the coming up of the ſeeds. In the next ſpring, the pots ſhould be plunged into an hotbed, and after that the ſeeds will ſoon appear. As much air as poſſible, and watering, ſhould be afforded them; and they muſt be hardened ſoon, to be ſet out. The pots ſhould then be plunged to their rims again in the natural mould; where they are to remain till October. Watering muſt be given them; and they ſhould alſo be ſhaded in the heat of the day. In October, they [illegible] be houſed, with other greenhouſe plants, or elſe ſet under a hot-bed frame, or ſome other cover, during winter. The third ſpring they ſhould be taken out of the larger pots, and each planted in a ſmaller, in which their growth may be aſſiſted by a gentle heat in a bed; but if they are planted up to the rims in a moiſt place, and ſhaded in dry weather, they will grow very well. Though by this time they ſhould have become hardy, yet it will be proper to ſhelter them the winter following in bad weather. They will require little more care during their ſtay in the pots, which may be either two, three, or more years, if they are large enough; when in ſpring they may be turned out, with the mould, into the places where they are to remain, which ought always to be moiſt and properly ſheltered.

Nyſſa, Nyu-che.

NYU-CHE, or KIN, an empire which aroſe in Eaſtern Tartary in the beginning of the 13th century. From the founder of this empire the late Chineſe emperor Kang-hi ſaid that his family was deſcended. See CHINA and TARTARY.

O.

O, The 14th letter and fourth vowel of our alphabet; pronounced as in the words *noſe*, *roſe*, &c.

The ſound of this letter is often ſo ſoft as to require it double, and that chiefly in the middle of words; as *gooſe*, *reproof*, &c. And in ſome words, this *oo* is pronounced like *u* ſhort, as in *flood*, *blood*, &c.

As a numeral, O was ſometimes uſed for 11 among the ancients; and with a daſh over it thus, Ō, for 11,000.

In the notes of the ancients, O. CON. is read *opus conductum*; O. C. Q. *opera conſilioque*; O. D. M. *operæ, donum munus*; and O. LO. *opus locatum*.

The Greeks had two O's; viz. omicorn, ο, and omega, ω; the firſt pronounced on the tip of the lips with a ſharper ſound; the ſecond in the middle of the mouth, with a fuller ſound, equal to *oo* in our language. The long and ſhort pronunciation of our O are equivalent to the two Greek ones; the firſt, as in ſuppoſe; the ſecond, as in *o*bey.

O is uſually denoted long by a ſervile *a* ſubjoined, as *moan*; or by *e* at the end of the ſyllable, as *bone*; when theſe vowels are not uſed, it is generally ſhort.

Among the Iriſh, the letter O, at the beginning of the name of a family, is a character of dignity annexed to great houſes. Thus, in the hiſtory of Ireland, we frequently meet with the *O Neals*, *O Carrols*, &c. conſiderable houſes in that iſland.

Camden obſerves, that it is the cuſtom of the lords of Ireland to prefix an O to their names to diſtinguiſh them from the commonalty.

The ancients uſed O as a mark of triple time; from a notion that the ternary, or number 3, was the moſt perfect of numbers, and therefore properly expreſſed by a circle, the moſt perfect of figures.

It is not, ſtrictly ſpeaking, the letter O, but the figure

Nyſſa.

mina. There is only one ſpecies, the *nyſſa aquatica* or tupelo tree. It is a deciduous tree or ſhrub, a native of moiſt or watery places in America, and conſiſts of two varieties: 1. The entire-leaved; and, 2. The ſerrated-leaved tupelo.

Planting and Gardening.

The entire-leaved tupelo tree, in its native ſoil and climate, grows to near 20 feet high; in this country its ſize varies according to the nature of the ſoil or ſituation. In a moiſt rich earth, well ſheltered, it comes near to 20 feet; in others, that are leſs ſo, it makes ſlower progreſs, and in the end is proportionally lower. The branches are not very numerous, and it riſes with a regular trunk, at the top of which they generally grow. The leaves are of a lanceolated figure, and of a fine light green colour. They [illegible] points, and are very ornamental, of a thickiſh [illegible]ence, ſoft, grow alternately on pretty long [illegible] and often retain their verdure late in the [illegible]. The flowers, which are not very ornamental, [illegible]uced from the ſides of the branches, growing [illegible]ingly, ſometimes many together, on a [illegible] They are of a greeniſh colour; and, in [illegible] where they naturally grow, are ſucceeded [illegible] encloſing oval, acute, furrowed nuts. [illegible] they ſeldom produce fruit.

The ſerrated-leaved tupelo tree grows uſually nearly 30 feet in height; and divides into branches near the top like the other. The leaves are oblong, pointed, of a light green colour, and come out without order on long footſtalks. The flowers come out from the wings of the leaves on long footſtalks. They are ſmall, of a greeniſh colour; and are ſucceeded by oval drupes, containing ſharp-pointed nuts, about the ſize of a French olive.

The propagation of theſe trees is from ſeeds, which come from America. As ſoon as they arrive, they ſhould be ſown in large pots of light ſandy earth an inch deep. The gardener (no plants come up the firſt ſpring), after this work is done, ſhould plunge his pots up to their rims in the natural ground; and if it be a moiſt place, it will be the better. Weeding muſt be obſerved during the ſummer; and a few furze-buſhes ſhould be pricked round the pots in November, which will prevent the ground from freezing, and forward the coming up of the ſeeds. In the next ſpring, the pots ſhould be plunged into an hotbed, and after that the ſeeds will ſoon appear. As much air as poſſible, and watering, ſhould be afforded them; and they muſt be hardened ſoon, to be ſet out. The pots ſhould then be plunged to their rims again in the natural mould; where they are to remain till October. Watering muſt be given them; and they ſhould alſo be ſhaded in the heat of the day. In October, they muſt be houſed, with other greenhouſe plants, or elſe ſet under a hot-bed frame, or ſome other cover, during winter. The third ſpring they ſhould be taken out of the larger pots, and each planted in a ſmaller, in which their growth may be aſſiſted by a gentle heat in a bed; but if they are planted up to the rims in a moiſt place, and ſhaded in dry weather, they will grow very well. Though by this time they ſhould have become hardy, yet it will be proper to ſhelter them the winter following in bad weather. They will require little more care during their ſtay in the pots, which may be either two, three, or more years, if they are large enough; when in ſpring they may be turned out, with the mould, into the places where they are to remain, which ought always to be moiſt and properly ſheltered.

Nyſſa, Nyu-che.

NYU-CHE, or Kin, an empire which aroſe in Eaſtern Tartary in the beginning of the 13th century. From the founder of this empire the late Chineſe emperor Kang-hi ſaid that his family was deſcended. See China and Tartary.

O.

O, The 14th letter and fourth vowel of our alphabet; pronounced as in the words *noſe*, *roſe*, &c.

The ſound of this letter is often ſo ſoft as to require it double, and that chiefly in the middle of words; as *gooſe*, *reproof*, &c. And in ſome words, this *oo* is pronounced like *u* ſhort, as in *flood*, *blood*, &c.

As a numeral, O was ſometimes uſed for 11 among the ancients; and with a daſh over it thus, Ō, for 11,000.

In the notes of the ancients, O. CON. is read *opus conductum*; O. C. Q. *opera conſilioque*; O. D. M. *operæ, donum munus*; and O. LO. *opus locatum*.

The Greeks had two O's; viz. omicorn, ο, and omega, ω; the firſt pronounced on the tip of the lips with a ſharper ſound; the ſecond in the middle of the mouth, with a fuller ſound, equal to *oo* in our language. The long and ſhort pronunciation of our O are equivalent to the two Greek ones; the firſt, as in ſuppoſe; the ſecond, as in obey.

O is uſually denoted long by a ſervile *a* ſubjoined, as *moan*; or by *e* at the end of the ſyllable, as *bone*; when theſe vowels are not uſed, it is generally ſhort.

Among the Iriſh, the letter O, at the beginning of the name of a family, is a character of dignity annexed to great houſes. Thus, in the hiſtory of Ireland, we frequently meet with the *O Neals*, *O Carrols*, &c. conſiderable houſes in that iſland.

Camden obſerves, that it is the cuſtom of the lords of Ireland to prefix an O to their names to diſtinguiſh them from the commonalty.

The ancients uſed O as a mark of triple time; from a notion that the ternary, or number 3, was the moſt perfect of numbers, and therefore properly expreſſed by a circle, the moſt perfect of figures.

It is not, ſtrictly ſpeaking, the letter O, but the figure of a circle O, or double CƆ, by which the modern ancients in muſic uſed to expreſs what they called *tempo perfecto*, or triple time. Hence the Italians call it *circolo*.

The ſeven antiphones, or alternate hymns of ſeven verſes, &c. ſung by the choir in the time of Advent, were formerly called *O*, from their beginning with ſuch an exclamation.

O is an adverb of calling, or interjection of ſorrow or wiſhing.

OAK, in botany. See Quercus.

The oak has been long known by the title of *monarch of the woods*, and very juſtly. It was well known, and often very elegantly deſcribed, by the ancient poets. The following deſcription from Virgil is exquiſite:

Veluti annoſo validam cum robore quercum
Alpini Boreæ, nunc hinc, nunc flatibus illinc
Eruere inter ſe certant: it ſtridor, et altæ
Conſternunt terram concuſſo ſtipite frondes;
Ipſa hæret ſcopulis; et quantum vertice ad auras
Ætherias, tantum radice in Tartara tendit.

Æn. iv. 441.

As o'er th' aerial Alps ſublimely ſpread,
Some aged *oak* uprears his reverend head;
This way and that the furious tempeſts blow,
To lay the monarch of the mountains low;
Th' imperial plant, though nodding at the ſound,
Though all his ſcatter'd honours ſtrew the ground;
Safe in his ſtrength, and ſeated on the rock,
In naked majeſty defies the ſhock:
High as the head ſhoots tow'ring to the ſkies,
So deep the root in hell's foundation lies.

Pitt.

The ancient druids had a moſt profound veneration for oak trees. Pliny † ſays, that "the druids (as the Gauls call their magicians or wiſe men) held nothing ſo ſacred as the miſletoe, and the tree on which it grows, provided it be an oak. They make choice of oak groves in preference to all others, and perform no rites without oak leaves; ſo that they ſeem to have the name of druids from thence, if we derive their name from the Greek," &c. (See Druids—definition, and N° 11.) Maximus Tyrius ſays the Celtæ or Gauls worſhipped Jupiter under the figure of a lofty oak (a).

† Nat. Hiſt. xvi. c. 44

This uſeful tree grows to ſuch a ſurpriſing magnitude, that were there not many well authenticated inſtances of them in our own country, they would certainly appear difficult of belief. In the 18th volume of the Gentleman's Magazine we have the dimenſions of a leaf twelve inches in length and ſeven in breadth, and all the leaves of the ſame tree were equally large. On the eſtate of Woodhall, purchaſed in 1775 by Sir Thomas Rumbold, Bart. late governor of Madras, an oak was felled which ſold for 43l. and meaſured 24 feet round. We are alſo told of one in Millwood foreſt, near Chaddeſly, which was in full verdure in winter, getting its leaves again after the autumn ones fell off." In Hunter's Evelyn's Sylva, we have an account of a very remarkable oak at Greendale; which Gough, in his edition of Camden, thus minutely deſcribes: "The Greendale oak, with a road cut through it, ſtill bears one green branch. Such branches as have been cut or broken off are guarded from wet by lead. The diameter of this tree at the top, whence the branches iſſue, is 14 feet 2 inches; at the ſurface of the ground 11¼ feet; circumference there 35 feet; height of the trunk [illegible]; height of the arch 10, width 6. Mr Evelyn mentions ſeveral more oaks of extraordinary ſize in Workſop park."

In the Gentleman's Magazine for 1773 we have an account of [illegible] differing very eſſentially from the common one [illegible] frequent about St Thomas in Devonſhire, and is in [illegible] county called *Lucombe* oak, from one William [illegible]combe who ſucceſsfully cultivated it near Exeter. [illegible] grows as ſtraight and handſome as a fir; its leaves [illegible] evergreen, and its wood as hard as that of [illegible] common oak. Its growth is ſo quick, as to exceed [illegible] 40 years the altitude and girth of the common [illegible] 100. It is cultivated in various places; Cornwall, Somerſetſhire, &c.

Mr du Hamel du Monceau, of the Royal Academy of Sciences at Paris (who wrote a treatiſe on huſbandry), gave an account in the year 1749 of an oak which he had kept in water eight years, and which yielded fine leaves every ſpring. The tree had, he ſays, four or five branches; the largeſt 19 or 20 lines round, and more than 18 inches long. It throve more in the two firſt years than it would have done in the beſt earth; it afterwards loſt its vigour, and rather decayed; which he attributed to a defect in the roots rather than to a want of aliment.

M. de Buffon made ſome experiments on oak trees; the reſult of which is recorded in the Gentleman's Magazine, 1754. He had compared barked with unbarked trees; and proves, we think with ſucceſs, from a variety of trials, that timber barked and dried ſtanding, is always heavier and conſiderably ſtronger than timber kept in its bark.

The bark of oak trees was formerly thought to be extremely uſeful in vegetation. One load (Mr Mills in his Treatiſe on Huſbandry informs us) of oak bark, laid in a heap and rotted, after the tanners have uſed it for dreſſing of leather, will do more ſervice to ſtiff cold land, and its effects will laſt longer, than two loads of the richeſt dung; but this has been ſtrenuouſly controverted. (See *Oak Leaves*.)

The bark, in medicine, is alſo a ſtrong aſtringent; and hence ſtands recommended in hæmorrhagies, alvine fluxes, and other preternatural or immoderate ſecretions; and in theſe it is ſometimes attended with good effects. Some have alleged, that by the uſe of this bark every purpoſe can be anſwered which may be obtained from Peruvian bark. But after ſeveral very fair trials, we have by no means found this to be the caſe. Beſides the bark, the buds, the acorns and their cups are uſed; as alſo the galls, which are excreſcences cauſed by inſects on the oaks of the eaſtern countries, of which there are divers ſorts; ſome perfectly round and ſmooth, ſome rougher with ſmall protuberances, but all generally having a round hole in them. All the parts of the oak are ſtyptic, binding, and uſeful in all kinds of fluxes and bleedings, either inward or outward. The bark is frequently uſed in gargariſms, for the relaxation of the uvula, and for ſore mouths and throats: it is alſo uſed in reſtringent clyſters and injections, againſt the pr[illegible] ani. The acorns, beaten to powder, are taken by the vulgar for pains in the ſide. [illegible] officinal preparation is the aqua [illegible]

(a) Camden informs us of a tradition (which, like moſt other traditions of this nature, ſeems to be founded in ignorance and foſtered by credulity) reſpecting an oak near Malwood caſtle, where Rufus was killed, viz. that it budded on Chriſtmas day, and withered before night. This tree, the ſame tradition reports to have been that againſt which Tyrrel's arrow glanced.

Oak Leaves. The uſes of oa[illegible] anning, in hot-beds, is generally known. [illegible] theſe purpoſes, however, oak leaves [illegible] anſwer equally well, or rather better. [illegible] notes to Dr Hunter's edition of Evelyn's T[illegible] Trees, we find the following directions [illegible] W. Speechly: The leaves are to be [illegible] as poſſible after they fall from the [illegible] into heaps, they ſhould immediat[illegible] ſome place near the hot-houſes, wher[illegible] couch. Mr Speechly ſays, it was his cuſtom [illegible] them round with charcoal hurdles, or any thing elſe, to keep them from being blown about the garden in windy weather. In this place they tread them well, and water them in caſe they happen to have been brought in dry. The heap is made ſix or ſeven feet thick, and covered over with old mats, or any thing elſe, to prevent the upper leaves from being blown away. In a few days the heap will come to a ſtrong heat. For the firſt year or two in which he uſed theſe leaves, our author did not continue them in the heap longer than ten days or a fortnight: but by this method of management they ſettled ſo much when brought to the hot-houſe, that a ſupply was very ſoon required; and he afterwards found, that it was proper to let them remain five or ſix weeks in the heaps before they are brought to the hot-houſe. In getting them into the pine pots, if they appear dry, they are to be watered, and again trodden down exceedingly well, in layers, till the pits are quite full. The whole is then covered with tan bark, to the thickneſs of two inches, and well trodden down, till the ſurface becomes ſmooth and even. On this the pine pots are to be placed in the manner they are to ſtand, beginning with the middle row firſt, and filling up the ſpaces between the pots with tan. In this manner we are to proceed to the next row, till the whole be finiſhed; and this operation is performed in the ſame manner as when tan only is uſed. The leaves require no farther trouble through the whole ſeaſon; as they will retain a conſtant and regular heat for 12 months without ſtirring or turning; and our author inform us, that if he may judge from their appearance when taken out (being always entire and perfect), it is probable they would continue their heat through a ſecond year; but, as an annual ſupply of leaves is eaſily obtained, the experiment is hardly worth making. After this, the pines will have no occaſion to be moved but at ſtated times of their management, viz. at the ſhifting them in their pots, &c. when at each time a little freſh tan ſhould be added to make up the deficiency ariſing from the ſettling of the beds; but this will be inconſiderable, as the leaves do not ſettle much after their long couching. During the firſt two years of our author's practice he did not uſe any tan, but plunged the pine pots into the leaves, and juſt covered the ſurface of the beds, when finiſhed, with a little ſaw-duſt, to give it a neatneſs. This method, however, was attended with one inconvenience; for, by the caking of the leaves they ſhrunk from the ſides of the pots, whereby they became expoſed to the air, and at the ſame time the heat of the beds was permitted to eſcape.

“ Many powerful reaſons (ſays Mr Speechly) may be given why oak leaves are preferable to tanners bark.

“ 1. They always heat regularly; for during the whole time that I have uſed them, which is near ſeven [illegible] I never once knew of their heating with violence; and this is ſo frequently the caſe with tan, that I affirm, and indeed it is well known to every perſon converſant in the management of the hot-houſe, that pines ſuffer more from this one circumſtance, than all the other accidents put together, inſects excepted.—When this accident happens near the time of their fruiting, the effect is ſoon ſeen in the fruit, which is exceedingly ſmall and ill-ſhaped. Sometimes there will be little or no fruit at all; therefore gardeners who make uſe of tan only for their pines, ſhould be moſt particularly careful to avoid an over heat at that critical juncture—the time of ſhowing the fruit.

“ 2. The heat of oak leaves is conſtant; whereas tanner's bark generally turns cold in a very ſhort time after its furious heat is gone off. This obliges the gardener to give it frequent turnings in order to promote its heating. Theſe frequent turnings, not to mention the expence, are attended with the worſt conſequences; for by the continual moving of the pots backwards and forwards, the pines are expoſed to the extremes of heat and cold, whereby their growth is conſiderably retarded; whereas, when leaves are uſed, the pines will have no occaſion to be moved but at the times of potting, &c. The pines have one peculiar advantage in this undiſturbed ſituation; their roots grow through the bottoms of the pots, and mat among the leaves in a ſurpriſing manner. From the vigour of the plants when in this ſituation, it is highly probable that the leaves, even in this ſtate, afford them an uncommon and agreeable nouriſhment.

“ 3. There is a ſaving in point of expence; which is no inconſiderable object in places where tan cannot be had but from a great diſtance.

“ 4. The laſt ground of preference is, that decayed leaves make good manure; whereas rotten tan is experimentally found to be of no value. I have often tried it both on ſand and clay, and on wet and dry land; and never could diſcover in any of my experiments, that it deſerved the name of a manure; whereas decayed leaves are the richeſt, and of all others the moſt proper manure for a garden. Leaves mixed with dung make excellent hot-beds; and I find that beds compounded in this manner, preſerve their heat much longer than when made entirely with dung; and [illegible] both caſes, the application of leaves will be a conſiderable ſaving of dung, which is a circumſtance on many accounts agreeable."

Oak-Leaf Galls. Theſe are of ſeveral kinds; the remarkable ſpecies called the *muſhroom gall* is never found on any other vegetable ſubſtance but theſe leaves: and beſide this there are a great number of other kinds.

The double gall of theſe leaves is very ſingular, becauſe the generality of productions of this kind affect only one ſide of a leaf or branch, and grow all one way: whereas this kind of gall extends itſelf both ways, and is ſeen on each ſide of the leaf, in form of two protuberances, oppoſite the one to the other. Theſe are of differently irregular ſhapes, but their natural figure ſeems that of two cones, with broad baſes, and very obtuſe points, though ſometimes they are round, or very nearly ſo.

Theſe make their firſt appearance on the leaf in April, and remain on it till June or longer. They are at firſt green, but afterwards yellowiſh, and are ſofter to the touch than many other of the productions of this kind: they are uſually about the ſize of a large pea, but ſometimes they grow to the bigneſs of a nut. When opened, they are found to be of that kind which are inhabited each by one inſect only, and each contains one cavity. The cavity in this is, however, larger than in any other gall of the ſize, or even in many others of three times the ſize; the ſides of it being very little thicker than the ſubſtance of the leaf.

It is not eaſy to aſcertain the origin of the ſeveral ſpecies of flies which are at times ſeen in this manner to come out of the ſame ſpecies of galls. It ſeems the common courſe of nature, that only one ſpecies of inſect forms one kind of gall; yet it may be, that two or three kinds may give origin to the ſame kind. There is, however, another occaſion of our ſeeing different ſpecies come out of different galls of the ſame kind: and this is the effect of the enemies of the proper inhabitants.

It might appear that the parent fly, when ſhe had formed a gall for the habitation of her worm offspring, had placed it in an impregnable fortreſs; but this is not the caſe; for it frequently happens, that a fly, as ſmall perhaps as that which gave origin to the gall, produces a worm which is of the carnivorous kind, as the other feeds on vegetable juices. This little fly, well knowing that where there is one of theſe protuberances on a leaf, there is a tender and defenceleſs inſect within, pierces the ſides of the gall, and depoſites her egg within it. This, when it hatches into a worm, feeds upon the proper inhabitant; and finally, after devouring it, paſſes into the chryſalis ſtate, and thence appears in the form of its parent fly, and is ſeen making its way out of the gall, in the place of the proper inhabitant.

On opening theſe leaf-galls, which are properly the habitation only of one animal, it is common to find two, the ſtronger preying upon the body of the other, and ſucking its juices as it does thoſe of the leaf: often it is found wholly employed in devouring its unoffending neighbour at once: this is probably the caſe when its time of eating is nearly over; and, in fine, where we find the gall inhabited by only one inſect, or containing only one chryſalis, as it ought in its natural ſtate to do, we are never certain that this is the proper inhabitant, as it may be one of theſe deſtroyers who has eaten up the other, and ſupplied its place. See Aphis and *Oak Pucaron*.

Oak Saw-duſt is now found to anſwer the purpoſes of tanning, as well, at leaſt, as the bark. See Tanning.

Oak of Jeruſalem. See Chenopodium.

OAKHAM, Ockham, or *Oakum*, in ſea-language, denotes the matter of old ropes untwiſted and pulled out into looſe hemp, in order to be uſed in caulking the ſeams, tree-nails, and bends of a ſhip, for ſtopping or preventing leaks.

OAKHAMPTON, a town of Devonſhire, which ſends two members to parliament; ſituated in W. Long. 4. 5. N. Lat. 50. 48.

OANNES, a being in Chaldean mythology, repreſented as half a man and half a fiſh. According to Beroſus and other fabulous writers, this monſter was the civilizer of the Chaldeans; to whom he taught a ſyſtem of juriſprudence ſo perfect as to be incapable of improvement. In diſcharging the duties of his office, he ſpent the day on dry land, but retired every night into the ocean or the river. See Mythology, N° [illegible].

OAR, a long piece of timber, flat at one end and round or ſquare at the other; and which being applied to the ſide of a floating veſſel, ſerves to make it advance upon the water.

That part of the oar which is out of the veſſel, and which enters into the water, is called the *blade*, or *waſh-plat*; and that which is within board is termed the *loom*, whoſe extremity being ſmall enough to be graſped by the rowers, or perſons managing the oars, is called the *handle*.

To puſh the boat or veſſel forwards by means of this inſtrument, the rowers turn their backs forward, and, dipping the blade of the oar in the water, pull the handle forward ſo that the blade at the ſame time may move aft in the water: but ſince the blade cannot be ſo moved, without ſtriking the water, this impulſion is the ſame as if the water were to ſtrike the blade from the ſtern towards the head: the veſſel is therefore neceſſarily moved according to this direction. Hence it follows, that ſhe will advance with the greater rapidity, by as much as the oar ſtrikes the water more forcibly. Thus it is evident, that an oar acts upon the ſide of a boat or veſſel like a lever of the ſecond claſs, whoſe fulcrum is the ſtation upon which the oar reſts on the boat's gunnel. In large veſſels, this ſtation is uſually called the *row-port*; but in lights and boats it is always termed the *row-lock*.

OARISTUS, or Oaristys, a term in the Greek poetry, ſignifying a dialogue between a huſband and his wife; ſuch as that in the ſixth book of the Iliad between Hector and Andromache.

Scaliger obſerves, that the oariſtus is not properly any particular little poem, or entire piece of poetry; but always a part of a great one. He adds, that the paſſage now cited in Homer is the only proper oariſtus extant in the ancient poets.

OAT, in botany. See Avena.

Under the word Avena it was obſerved, that the native place of the common oat, cultivated in our fields, is unknown; that the only account of it, in its natural ſtate, which we then had, is in Anſon's Voyage; and that the report of ſuch an author reſpecting facts in natural hiſtory is not entitled to implicit credit. We had not then ſeen the Travels of Mr Bruce, whoſe botanical knowledge is very ſuperior to that of moſt voyagers, or we ſhould have mentioned his account of the oats which he found growing wild in Arooſſi, a ſmall territory in Abyſſinia, not far from the ſource of the Nile: (See Nile). "Wild oats (ſays he) grow up here ſpontaneouſly to a prodigious height and ſize, capable often of concealing both the horſe and his rider, and ſome of the ſtalks being little leſs than an inch in circumference. They have, when ripe, the appearance of ſmall canes. The inhabitants make no ſort of uſe of this grain in any period of its growth: the uppermoſt thin huſk of it is beautifully variegated with a changeable purple colour; the [illegible] perfectly good. I often made the meal into cakes in remembrance of Scotland." Our author informs us that the Abyſſinians could never be brought to eat theſe cakes, which they ſaid were bitter, [illegible] ſtomachs, and made them thirſty. He is, however, decidedly of opinion, that the wild oat of Arooſſi is the oat in its original ſtate; and that it [illegible] everywhere in Europe. From the [illegible] ſtates, this opinion ſeems to be well founded.

OATH, an affirmation or promiſe, accompanied with an invocation of God to witneſs what we ſay; and with an imprecation of his vengeance, or a renunciation of his favour, if what we affirm be falſe, or what we promiſe be not performed (a).

The laws of all civilized ſtates have required the ſecurity of an oath for evidence given in a court of juſtice, and on other occaſions of high importance (b); and the Chriſtian religion utterly prohibits ſwearing, except when oaths are required by legal authority. Indeed no ſerious and reflecting theiſt, whether he admit the truth of revelation or not, can look upon ſwearing on trivial occaſions as any thing elſe than a ſin of a very heinous nature. To call upon that infinite and omnipreſent Being, who created and ſuſtains the univerſe, to witneſs all the impertinence of idle converſation, of which great part is commonly uttered at *random*, betrays a ſpirit ſo profane, that nothing ſhort of experience could make us believe it poſſible for a creature endowed with reaſon and reflection to be habitually guilty of a practice ſo impious. No man can plead in extenuation of this crime, that he is tempted to ſwear by the importunity of any appetite or paſſion implanted in the human breaſt: for the utterance of a profane oath communicates no pleaſure, and removes no uneaſineſs: it neither elevates the ſpeaker, nor depreſſes the hearer.

Quakers and *Moravians*, ſwayed by theſe conſiderations, and by the ſenſe which they put upon certain texts of Scripture, refuſe to ſwear upon any occaſion, even at the requiſition of a magiſtrate, and in a court of juſtice. Theſe ſcruples are groundleſs; and ſeem to proceed from an incapacity to diſtinguiſh between the proper uſe and abuſe of ſwearing. It is unqueſtionably impious to call upon God to witneſs impertinences, or to uſe his tremendous name as a mere *expletive* in converſation; but it by no means follows, that we may not piouſly call upon him to witneſs truths of importance, or invoke his name with reverence and ſolemnity. No individual could, without groſs profaneneſs, pray for a thouſand times more wealth than he may ever have occaſion to uſe; but it is never thought profane to pray "day by day for our daily bread, for rain from heaven, and fruitful ſeaſons." If it be lawful to aſk of God theſe earthly [illegible] becauſe he alone can beſtow them; it cannot ſurely be unlawful, where the lives or properties of our neighbours, or the ſecurity of government is concerned, to invoke him with reverence to witneſs the truth of our aſſertions, or the ſincerity of our intentions; becauſe of our truth in many caſes, and of our ſincerity in all, none but he can be the witneſs.

The text of Scripture upon which the Quakers chiefly reſt their argument for the unlawfulneſs of all ſwearing under the Goſpel, is our Saviour's prohibi-

---

(a) The word *oath* is a corruption of the Saxon *eoth*. It is often in England called a *corporal oath*, becauſe, in the days of popery, the perſon was ſworn over the hoſt or *corpus Chriſti*.

(b) The various oaths required by different nations at different times, and the various forms, &c. of impoſing them, is a ſubject of very conſiderable extent and curioſity: An account of them does not fall within the plan of the preſent article; it would indeed extend it to an undue length: we cannot, however, omit obſerving, what is doubtleſs very remarkable, that the grand impoſtor Mahomet taught the Moſlems, that their oaths might be diſſolved. This wonderful doctrine is contained in the 66th chapter of the Koran; which, to free himſelf from his promiſe and oath to Hafsa his ſpouſe, he pretended was revealed. What the uſe of oaths is in ſuch circumſtances, or what ſecurity they afford for performance, it is difficult to aſcertain.

It is alſo very remarkable, that an oath reſpecting marriages was the cauſe of the firſt divorce at Rome. The circumſtance happened about the year of the city 525, Poſthumius Albinus and Spurius Carvilius being conſuls. The cenſors of this year obſerving the population declining, and imagining it proceeded from intereſted marriages and promiſcuous cohabitation, obliged all the citizens to ſwear, that they would not marry with any other view than that of peopling the republic. It raiſed, however, many ſcruples, and occaſioned many domeſtic ruptures. Among the reſt, one Carvilius Ruga, a man of diſtinction, imagined that he was bound by his oath to divorce his wife, whom he paſſionately loved, becauſe ſhe was barren, which was the firſt inſtance of a divorce at Rome from its foundation, though the marriage laws of the kings allowed it; it afterwards, however, became ſhamefully frequent. This is alſo a ſtriking inſtance of the great attention paid to oaths among the Romans: it is remarked indeed by all writers, that they paid a moſt profound reſpect to them; and on that we know they founded their hopes of ſucceſs in war.

tion (Mat. v. 34.): "I ſay into you, ſwear not at all." But whoever ſhall take the trouble of turning over his Bible, and looking at the context, will perceive, that it is only in *ordinary converſation*, and by no means in courts of juſtice, that our Lord prohibits his followers from ſwearing at all. There is no evidence whatever, that ſwearing by *heaven*, by *the earth*, by *Jeruſalem*, or by their own *heads*, was the form of a *judicial oath* in uſe among the Jews. On the contrary, we are told by *Maimonides**, that "if any man ſwear by heaven or by earth, yet this is not an oath;" which ſurely he could not have ſaid, had ſuch been the forms of judicial ſwearing. Indeed they could not have admitted ſuch forms into their courts without expreſsly violating the law of Moſes, who commands them to "Fear the Lord (JEHOVAH) their God, to ſerve him, and to ſwear by his NAME." But the Jews, as every one knows, had ſuch a reverence for the name *Jehovah*, that they would not pronounce it on ſlight occaſions, and therefore could not ſwear by that name in common converſation. Hence, to gratify their propenſity to common ſwearing, they invented ſuch oaths as, by *heaven*, by *earth*, by *Jeruſalem*, by *the life of thy head*, &c. and by this contrivance they thought to avoid the guilt of profaning the name JEHOVAH. Theſe, however, being appeals to inſenſible objects, either had no meaning, or were in fact, as our Saviour juſtly argues, oaths by that God whoſe creatures they were; ſo that the Jew who ſwore them was ſtill guilty of profaneneſs towards the very JEHOVAH whoſe name his ſuperſtition would not permit him to pronounce. But what puts it beyond all doubt that the uſe of judicial oaths is not wholly prohibited in the goſpel, is the conduct of our Saviour himſelf as well as of his apoſtle St Paul. When Jeſus was ſimply *aſked* by the high prieſt, what it was which certain falſe witneſſes teſtified againſt him? we are told by the evangeliſts, that "he held his peace:" but being *adjured* by the living God to declare whether he was the Chriſt, the Son of God, or not, he immediately anſwered the high prieſt, without objecting to the *oath* (for ſuch it was) upon which he was examined. "St Paul, in his Epiſtle to the Romans†, ſays, '*God is my witneſs*, that, without ceaſing, I make mention of you in my prayers;' and to the Corinthians, ſtill more ſtrongly, '*I call God for a record upon my ſoul*, that, to ſpare you, I came not as yet to *Corinth*.' Both theſe expreſſions are of the nature of oaths; and the author of the Epiſtle to the Hebrews ſpeaks of the cuſtom of ſwearing judicially without any mark of cenſure or diſapprobation; 'Men verily ſwear by the greater; and an oath, for confirmation, is to them an end of all ſtrife.'"

But though a nation has an undoubted right to require the ſecurity of an oath upon occaſions of r importance, we do not heſitate to ſay, that, in our opinion, it is ſomething worſe than bad policy to multiply oaths, and to hold out to the people temptations to perjure themſelves. The ſecurity which an oath affords, depends entirely upon the reverence which attaches to it in the mind of him by whom it is given; but that reverence is much weakened by the frequency of oaths, and by the careleſs manner in which they are too often adminiſtered. An excellent moraliſt ‡ obſerves, with truth, that "the levity and frequency with which oaths are adminiſtered, has brought about a general inadvertency to the obligation of them, which both in a religious and political view is much to be lamented; and it merits (continues he) public conſideration, whether the requiring of oaths on ſo many frivolous occaſions, eſpecially in the cuſtoms, and in the qualification for petty offices, has any other effect than to make them cheap in the minds of the people. A pound of tea cannot travel regularly from the ſhip to the conſumer without coſting *half a dozen oaths* at leaſt; and the ſame ſecurity for the due diſcharge of his office, namely that of an oath, is required from a *church warden* and an *archbiſhop*, from a [illegible] *conſtable* and the *chief juſtice* of England. Let the [illegible] continue its own ſanctions, if they be thought requiſite; but let it ſpare the ſolemnity of an [illegible] and where it is neceſſary, from the want of ſomething better to depend upon, to accept a man's own word or own account, let it annex to prevarication penalties proportioned to the public conſequence of the offence."

That theſe pernicious conſequences of frequent oaths are not felt only in England, we have the evidence of another reſpectable writer, whoſe acuteneſs well qualified him to obſerve, whilſt his ſtation in ſociety furniſhed him with the beſt opportunities of obſerving, the effects of repeated ſwearing upon the morals of Scotchmen. "Cuſtomhouſe oaths (ſays Lord Kames*) have become ſo familiar among us, as to be ſwallowed without a wry face; and it is certain that bribery and perjury in electing parliment members are not approaching to the ſame cool ſtate? Men creep on to vice by degrees. Perjury, in order to ſupport a friend, has become cuſtomary of late years; witneſs fictitious qualifications in the electors of parliament-men, which are made effectual by perjury: yet ſuch is the degeneracy of the preſent times (c), that no man is the worſe thought of upon that account. We muſt not flatter ourſelves, that the poiſon will reach no farther: a man who boggles not at perjury to ſerve a friend, will in time become ſuch an adept, as to commit perjury in order to ruin a friend when he becomes an enemy."

Beſides the frequency of oaths, we have mentioned the irreverent manner in which they are too often adminiſtered as one of the cauſes which make them cheap in the eſtimation of the people. In this view, the *form* of the oath, and the *ceremonies* with which it is required to be taken, are of conſiderable importance. "The

‡ *Mr Paley.*

* *Sketches of the Hiſtory of Man.*

(c) Such was the caſe when his Lordſhip wrote. Some deciſions of the houſe of peers, however, have ſince that period changed men's opinions reſpecting the legality of theſe votes and the innocence of the means by which they were made effectual. It is to be hoped that ſuch a reformation will ſoon be made of the laws by which elections are regulated in Scotland, as will render the temptations to perjury leſs numerous than they have hitherto been.

" The forms of oaths in Chriſtian countries (ſays Mr Paley) are very different; but in none I believe worſe contrived either to convey the meaning or to impreſs the obligation of an oath, than in England. In that country the juror, after repeating the promiſe or affirmation which the oath is intended to confirm, adds, 'ſo help me God;' or more frequently the ſubſtance of the oath is repeated to the juror by the officer or magiſtrate who adminiſters it; adding in the concluſion, 'ſo help you God.' The energy of the ſentence reſides in the particle *ſo; ſo*, i. e. *hac lege*, 'upon condition of my ſpeaking the truth, or performing this promiſe, may God help me, and not otherwiſe.' The juror, whilſt he hears or repeats the words of the oath, holds his right hand upon a Bible, or other book containing the four goſpels. 'The concluſion of the oath ſometimes runs, '*ita me Deus adjuvet, et hac ſancta evangelia*,' or 'ſo help me God, and the contents of this book;' which laſt clauſe forms a connexion between the words and action of the juror, which before was wanting. The juror [illegible] kiſſes the book."

This obſcure and elliptical form, [illegible] author juſtly obſerves, is ill calculated [illegible] the juror with reverence: and he ſeems [illegible] great preference due to the form of judicial oaths [illegible] Scotland. In that country the juror holds up [illegible] right hand towards heaven, and ſwears by Almighty God, and as he ſhall anſwer to God at the great day of judgment, "that he will tell the truth, the whole truth, and nothing but the truth, ſo far as he knows, or it ſhall be aſked of him." This, if adminiſtered with dignity and reverence, is an oath ſufficiently ſolemn and well calculated to have the proper effect upon the mind of the juror, as it brings immediately into his view the Author of his being, and the awful day of final retribution when every man ſhall receive the things done in his body according to that he hath done, whether it be good or evil. But when the magiſtrate, as is too often the caſe, repeats this ſolemn invocation without riſing from his ſeat at the name of the ſupreme Being, and in a tone of careleſſneſs which may convey to the ignorant juror an opinion that he has himſelf no ſerious belief that there ever will be a great day of judgment, the form, however excellent, makes not its full impreſſion.

But let us ſuppoſe the oath to be adminiſtered with the greateſt dignity and reverence, the words of the promiſe itſelf appear to us by no means unexceptionable. In a trial on life and death, we ſhould be glad to know wh. this oath binds the witneſs to declare. Is he to tell *all that he knows* touching the matter in queſtion? or only all that ſhall be *aſked* of him? If he be obliged, in virtue of his oath, to tell all that he knows, the clauſe—"or it ſhall be aſked of you" is ſuperfluous, and calculated to miſlead. If he be bound to tell nothing more of the truth than what ſhall be aſked of him, the word *or* ſhould be changed into *and;* he ſhould ſwear "to tell the truth, &c. ſo for as he knows, *and* it ſhall be aſked of him." The court, we believe, conſiders the witneſs as bound to declare every thing which he knows touching the matter in queſtion. The greater part of witneſſes, on the other hand, conſider themſelves as bound no farther by their oath than to give true anſwers to ſuch queſtions as ſhall be aſked of them. They would do well, however, to remember, that as oaths are deſigned for the ſecurity of the *public*, they muſt be interpreted in the ſenſe in which the public intends them, otherwiſe they afford no ſecurity. But the ſenſe of the public is the law; and as it belongs to the court to declare what the mind of the law is, the witneſs, who has any doubt concerning the extent of the obligation impoſed on him by the words of this oath, ſhould apply to the court for a ſolution of that doubt, which will be a ſafe guide to him reſpecting the evidence which he is to give. Should the court, in reſolving the doubts of a witneſs, give an opinion concerning the ſenſe of any other part of the oath contrary to what he apprehends to be the deſign of the law in impoſing it, he is bound to diſregard ſuch opinion; becauſe it is only when [illegible] himſelf is doubtful that the court has a right to interfere, and becauſe in all moral queſtions men muſt [illegible]ally determined by their own judgment and conſcience.

There is one caſe, and but one, in which, whatever ſenſe be put upon the words of the oath, no witneſs is obliged to declare the *whole* truth. It is when ſuch declaration would tend to accuſe himſelf of ſome legal crime; for as the laws of Scotland and England conſtrain no man to become his own accuſer, they muſt be conſidered as impoſing the oath of teſtimony with this tacit reſervation. "The exception, however †, muſt be confined to *legal* crimes. A point [illegible]nour, of delicacy, or of reputation, may make a witneſs backward to diſcloſe ſome circumſtance with which he is acquainted; but is no excuſe for concealment, unleſs it could be ſhown, that the law which impoſes the oath, intended to allow this indulgence to ſuch motives. The exception is alſo withdrawn by compact between the magiſtrate and the witneſs, when an accomplice is admitted to give evidence againſt the partners of his crime." But theſe are a ſort of witneſſes to whom a ſenſible jury will always liſten with a very cautious ear.

Oaths are either *aſſertory* or *promiſſory*. Aſſertory oaths are required both to confirm our veracity in evidence, and to give ſecurity to the public that we *believe* certain propoſitions conceived to be of public importance. An oath in *evidence* binds the juror to declare what he *knows* to be true, and nothing *but* what he knows to be true. An oath required to aſſure the public of our *belief* in the *truth* of any propoſition, cannot, without the guilt of perjury, be taken by any man, who, at the time of ſwearing, has the ſlighteſt doubt whether the propoſition be really true. Such an oath, however, though it unqueſtionably requires the ſincerity of the juror's belief at the time when it is given cannot oblige him to continue in that belief as long as he may live; for belief is not in any man's power: it is the neceſſary conſequence of evidence, which *compels* the aſſent of the mind according as it appears to preponderate on the one ſide or on the other. No man, therefore, can be juſtly accuſed of perjury for holding opinions contrary to thoſe which he may formerly have ſworn to believe; becauſe his belief at the time of emitting his oath may have been the neceſſary reſult of the evidence which then appeared before him; and his change of opinion may have reſulted with the ſame neceſſity from ſuperior

† *Paley's Moral Philoſophy.*

evidence which had been ſince thrown into the oppoſite ſcale, and made it preponderate. On this account, we cannot help thinking, that all aſſertory oaths, except ſuch as are neceſſary to confirm teſtimony reſpecting *facts*, ought either to be aboliſhed or expreſſed with great caution. Of truths intuitively certain or capable of rigid demonſtration, no man of common ſenſe can entertain a doubt; and therefore the public never requires from individuals the ſolemnity of an oath as an aſſurance of their believing ſuch truths. But with reſpect to the truth of propoſitions which admit of nothing ſuperior to moral evidence on either ſide, a man of the moſt ſteady virtue may think differently at different periods of his life; and in ſuch caſes, the effect of an oath, if it have any effect, can only be either to ſhut the man's eyes againſt the light, or to make his integrity be cauſeleſsly queſtioned by thoſe who ſhall obſerve his change of belief.

Promiſſory oaths cannot, without the guilt of perjury, be given by him, who, at the time of ſwearing, knows that it will not be in his power to fulfil the promiſe, or who does not ſeriouſly intend to fulfil it. A promiſſory oath cannot, without great guilt, be given by any man, who at the time of ſwearing believes the object of the promiſe to be in itſelf unlawful; for if he ſeriouſly mean to fulfil his oath, he calls upon Almighty God to witneſs his intention to commit a crime. Promiſſory oaths give to the public greater ſecurity than a ſimple promiſe; becauſe the juror having the thoughts of God and of religion more upon his mind at the one time than at the other, offends with a higher hand, and in more open contempt of the divine power, knowledge, and juſtice, when he violates an oath, than when he breaks a promiſe. Yet it is certain that promiſſory oaths, though more ſolemn and ſacred, cannot be binding, when the promiſe without an oath would not be ſo in an inferior degree; for the ſeveral caſes of which, ſee Promise and Allegiance.

Coronation Oath. See King.

OATHLAW, the name of a pariſh in Angus, about two miles from Forfar, chiefly remarkable for the remains of a Roman camp called *Battle-dykes* (vulgarly *Black-dykes*), which is about a mile weſt of the church.

OBADIAH, or the *Prophecy of* Obadiah, a canonical book of the Old Teſtament, which is contained in one ſingle chapter; and is partly an invective againſt the cruelty of the Edomites, who mocked and derided the children of Iſrael as they paſſed into captivity; and with other enemies, their confederates, invaded and oppreſſed thoſe ſtrangers, and divided the ſpoil among themſelves; and partly a prediction of the [illegible] of Iſrael, and of the victory and triumph of the [illegible] church over her enemies.

Obadiah, the prophet, is believed to have been the ſame with the governor of Ahab's houſe, mentioned in the firſt book of Kings, (xviii. 3, &c.) who hid and fed the hundred prophets whom Jezebel would have deſtroyed; and ſome ſay, that he was that Obadiah whom Joſiah made overſeer of the works of the temple, (2 Chron. xxxiv. 12.) The truth is, that when he lived or propheſied is wholly uncertain: though moſt writers make him cotemporary with Hoſea, Amos, and Joel.

Obadiah, a valiant man of David's army, who came to join him in the wilderneſs, with ſeveral others of the tribe of Gad, (1 Chron. xii. 9.)

This was alſo the name of one of thoſe whom King Jehoſhaphat ſent into the cities of Judah to inſtruct the people in their religion, (2 Chron. xvii. 7.) It was alſo the name of one of the principal men of Judah, who ſigned the covenant that Nehemiah renewed with the Lord, (Nehem. x. 5.)

OBED-EDOM, ſon of Jeduthun, a Levite, (1 Chr. xvi. 38.) and father of Shemaiah, Jehozabad, Joah, Sacar, Nathaneel, Ammiel, Iſſachar, and Peulthai. He had a numerous family, ſays the Scripture, (1 Chr. xxvi. 4.) becauſe the Lord bleſſed him; and this is the occaſion of the bleſſing. When David transferred the ark of the covenant to the city of Jeruſalem, Uzzah having raſhly laid hands on the ark, which he thought to be in danger of falling, was ſmitten of God, and died upon the ſpot. David, terrified at this [illegible] remove the ark into the place he [illegible] in his own houſe, but ſet it up in [illegible] edom, which was near the place [illegible] been ſtruck dead. But the preſence [illegible] only created no temporal misfortune to [illegible] of this Levite, but on the contrary the [illegible] d upon him all ſorts of bleſſings; which [illegible] ed David ſome months after to remove it to the place he had appointed for it. Afterwards Obed-edom and his ſons were aſſigned to be keepers of the doors of the temple, (1 Chron. xv. 18, 21.) In the ſecond book of Samuel, (vi. 10.) Obed-edom is called the Gittite, probably becauſe he was of Gathrimmon, a city of the Levites beyond Jordan, (Joſh. xxi. 24, 25.)

OBELISK, in architecture, a truncated, quadrangular, and ſlender pyramid, raiſed as an ornament, and frequently charged either with inſcriptions or hieroglyphics.

Obeliſks appear to be of very great antiquity, and to have been firſt raiſed to tranſmit to poſterity precepts of philoſophy, which were cut in hieroglyphical characters: afterwards they were uſed to immortalize the great actions of heroes, and the memory of perſons beloved. The firſt obeliſk mentioned in hiſtory was that of Ramaſes king of Egypt, in the time of the Trojan war, which was 40 cubits high. Phius, another king of Egypt, raiſed o[illegible] of 55 cubits; and Ptolemy Philadelphus, anoth[illegible] 88 cubits, in [illegible] ſinoë. Auguſtus erected [illegible] at Rome in th[illegible] which ſerved to [illegible] the hours on a horizontal dial, drawn on th[illegible]. They were called by the [illegible] s *of the ſun*, becauſe they [illegible] as ſtyles or gnomons [illegible] ſtill call them *Pharaoh's needles*; whence th[illegible] them *eguglia*, and the French *aiguilles*.

The famous obeliſks called the *devil's arrows*, now reduced to three, the fourth having been taken down in the laſt century, ſtand about half a mile from the town of Borough-Bridge to the ſouth-weſt, in three fields, ſeparated by a lane, 200 feet aſunder, nearly on high ground ſloping every way. Mr Drake urges many arguments for their Roman antiquity, and plainly proves them to be natural and brought from Hampton quarries about five miles off, or from Ickly 16 miles off. The croſs in the town, 12 feet high, is of the ſame kind of ſtone. The eaſtermoſt or higheſt is 22 feet and a half high by 4 broad, and 14¼ in girth; the ſecond 21½ by 55½; the third 16½ by 84. Stukeley's meaſures differ. The flutings are cut in the ſtone but not through: the talleſt ſtands alone, and leans to the ſouth. Plot and Stukeley affirm them to be Britiſh monuments, originally hewn ſquare. Dr Gale ſuppoſed that they were Mercuries, which have loſt their heads and inſcriptions; but in a MS note in his Antoninus, he acknowledges that he was miſinformed and that there was no cavity to receive a buſt.

On the north ſide of Penrith, in the churchyard, are two ſquare obeliſks, of a ſingle ſtone each, 11 or 12 feet high, about 12 inches diameter, and 12 by 8 at the ſides, the higheſt about 18 inches diameter, with ſomething like a tranſverſe piece [illegible] into a round baſe. They are 14 [illegible] tween them is a grave encloſed [illegible] ſemicircular ſtones of the unequal lengths of ſix, and four and a half, and two feet high, [illegible] on the outſides rude carving, and the tops notched. This is called the *Giant's grave*, and aſcribed to Sir Ewan Ceſarius, who is ſaid to have been as tall as one of the columns, and capable of ſtretching his arms from one to the other; to have deſtroyed robbers, and wild boars in Englewood foreſt; and to have had an hermitage hereabouts called *Sir Hugh's parlour*; but the conjectures reſpecting them are ſo various and contradictory, that our readers will readily excuſe our enlarging on them.

A little to the weſt of theſe is a ſtone called the *Giant's Thumb*, ſix feet high, 14 inches at the baſe contracted to 10, which is no more than a rude croſs, ſuch as is at Langtown in Cumberland and elſewhere; the circle of the croſs 18 inches diameter.

M. Pouchard, in the memoirs of the Academy of Inſcriptions, gives a very curious account of ſome celebrated Egyptian obeliſks. We cannot afford room to follow him; but thoſe who wiſh for further information on the ſubject, and who are not poſſeſſed of the original, will find a very good account of them in the Gentleman's Magazine for June 1748.

OBJECT, in philoſophy, ſomething apprehended or preſented to the mind by ſenſation or imagination. See Metaphysics, Part I. Chap. I. Sect. II.

Object-*Glaſs* of a *Teleſcope*, or *Microſcope*, the glaſs placed at [illegible] the tube which is next the object. See Optics and Microscope.

OBJECTION, ſomething urged to overthrow a poſition, or a difficulty raiſed againſt an allegation or propoſition of a perſon we are diſputing with.

OBJECTIVE, is uſed in the ſchools, in ſpeaking of a thing which exiſts no otherwiſe than as an object known. The exiſtence of ſuch a thing is ſaid to be objective.

OBIT, (Lat.) ſignifies a funeral ſolemnity, or office for the dead, moſt commonly performed when the corpſe lies in the church uninterred: Alſo the anniverſary office. (2 Cro. 51 Dyer 313). The anniverſary of any perſon's death was called the *obit*; and to obſerve ſuch day with prayers and alms, or other commemoration, was the keeping of the obit. In religious houſes they had a regiſter, wherein they entered the obits or obitual days of their founders and benefactors; which was thence termed the *obituary*. The tenure of obit or chantry lands is taken away and extinct by 1 Edward VI. c. 14. and 15 Car. II. c. 9.

OBLATI, in church hiſtory, were ſecular perſons, who devoted themſelves and their eſtates to ſome monaſtery, into which they were admitted as a kind of lay brothers. The form of their admiſſion was putting the bell ropes of the church round their necks, as a mark of ſervitude. They wore a religious habit, but different from that of the monks.

OBLIGATION, in general, denotes any act whereby a perſon becomes bound to another to do ſomething; as to pay a ſum of money, be ſurety, or the like.

Obligations are of three kinds, *viz.* natural, civil, and mixed. Natural obligations are entirely founded on natural equity; civil obligation on civil authority alone, without any foundation in natural equity; and mixed obligations are thoſe which, being founded on natural equity, are farther enforced by civil authority.

In a legal ſenſe, obligation ſignifies a bond, wherein is contained a penalty, with a condition annexed for the payment of money, &c. The difference between it and a bill is, that the latter is generally without a penalty or condition, though it may be made obligatory; and obligations are ſometimes by matter of record, as ſtatutes and recognizances. See the article Bond.

Moral Obligation. See Moral Philosophy, N° 58, &c.

OBLIQUE, in geometry, ſomething aſlant, or that deviates from the perpendicular. Thus an oblique angle is either an acute or obtuſe one, *i. e.* any angle except a right one.

Oblique Caſes, in grammar, are all the caſes except the nominative. See Grammar.

Oblique Line, that which, falling on another line, makes oblique angles with it, *viz.* one acute, and the other obtuſe.

Oblique Planes, in dialling, are thoſe which decline from the zenith, or incline towards the horizon. See Dial.

Oblique Sailing, in navigation, is when a ſhip ſails upon ſome rhumb between the four cardinal points, making an oblique angle with the meridian; in which caſe ſhe continually changes both latitude and longitude. See Navigation, Chap. VIII.

OBLIQUUS, in anatomy, a name given to ſeveral muſcles, particularly in the head, eyes, and abdomen. See Anatomy, *Table of the Muſcles.*

OBLONG, in general, denotes a figure that is longer than broad; ſuch is a parallelogram.

OBOLARIA, in botany: A genus of the angioſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 40th order, *Perſonatæ*. The calyx is bifid; the corolla campanulated and quadrifid; the capſule unilocular, bivalved, and polyſpermous; the ſtamina riſing from the diviſions of the corolla.

OBOLUS, an ancient ſilver money of Athens, the ſixth part of a drachma; worth ſomewhat more than a penny-farthing ſterling.—The word comes from the Greek οβολος, or οβελος, "ſpit, or broach;" either becauſe it bore ſuch an impreſſion; or becauſe, according to Euſtathius, it was in form thereof. But thoſe now in the cabinets of the antiquaries are round.

Obolus, in medicine, is uſed for a weight of ten grains, or half a ſcruple.

OBOTH, an encampment of the Hebrews in the wilderneſs. From Punon they went to Oboth, and from Oboth to Ije-abarim, (Numb. xxi. 10. xxxiii. 43.) Ptolemy ſpeaks of a city called Oboda, or Eboda, in Arabia Petræa, which is the ſame as Oboth. Pliny and the geographer Stephanus mention it alſo. Stephanus makes it belong to the Nabathæans, and Pliny to the Helmodeans, a people of Arabia. It was at Oboth that they worſhipped the god Obodos, which Tertullian joins with Duſares, another god or king of this country.

OBRECHT (Ulric), a learned German, born of a noble family at Straſburg in 1646, where he filled the chairs of civil law and hiſtory with great diſtinction. He was of the Proteſtant religion; but when Louis XIV. made himſelf maſter of Straſburg, and went there with his court, he was prevailed on to change; and accordingly abjured in 1684, and put his inſtrument into the hands of Boſſuet biſhop of Meaux. The next year the king nominated him to preſide in his name in the ſenate of Straſburg, with the title of prætor royal, in imitation of the ancient Romans; from which time Mr Obrecht applied himſelf entirely to public affairs. He was the editor, tranſlator, and writer, of ſeveral learned works; and died in 1701.

OBREPTITIOUS, an appellation given to letters patent, or other inſtruments, obtained of a ſuperior by ſurpriſe, or by concealing from him the truth.

OBSCURE, ſomething that is dark and reflects little light in material objects, or that is not clear and intelligible in the objects of the intellect.

OBSECRATION, in rhetoric, a figure whereby the orator implores the aſſiſtance of God or man.

OBSEQUENS (Julius), a Latin writer, conjectured to have lived before the emperor Honorius's reign. He made a collection of the prodigies which Livy related in his hiſtory. There are ſeveral editions of thoſe remains. Lycoſthenes endeavoured to ſupply what was wanting in the original.

OBSEQUIES, the ſame with funeral ſolemnities. See Funeral.

OBSERVATION, among navigators, ſignifies the taking the ſun's or the ſtars meridian altitude, in order thereby to find the latitude.

OBSERVATORY, a place deſtined for obſerving the heavenly bodies; being generally a building erected on ſome eminence, covered with a terrace for making aſtronomical obſervations.

The more celebrated obſervatories are, 1. The Greenwich obſervatory, built in 1676, by order of Charles II. at the ſolicitation of Sir Jonas Moore and Sir Chriſtopher Wren; and furniſhed with the moſt accurate inſtruments; particularly a noble ſextant of ſeven feet radius, with teleſcopic ſights.

2. The Paris obſervatory, built by the order of Louis XIV. in the Fauxbourg St Jacques.

It is a very ſingular, but withal a very magnificent building, the deſign of Monſieur Perault; it is 80 feet high, and at top is a terrace.

The difference in longitude between this and the Greenwich obſervatory is 2° 20′.

In it is a cave or cellar, of 170 feet deſcent, for experiments that are to be made far from the ſun, &c. particularly ſuch as relate to congelations, refrigerations, indurations, conſervations, &c.

3. Tycho Brahe's obſervatory, which was in the little iſland Ween, or Scarlet Iſland, between the coaſts of Schonen and Zealand in the Baltic. It was erected and furniſhed with inſtruments at his own expence, and called by him *Uraniburg*. Here he ſpent twenty years in obſerving the ſtars; the reſult is his catalogue.

4. Pekin obſervatory. Father Le Compte deſcribes a very magnificent obſervatory, erected and furniſhed by the late emperor of China, in his capital, at the interceſſion of ſome Jeſuit miſſionaries, principally Fa- [illegible] whom he made his chief obſerver.—[illegible] exceedingly large; but the divi- [illegible] and the contrivance in ſome reſpects [illegible] than that of the Europeans. The [illegible] An armillary zodiacal ſphere of ſix feet dia- [illegible] quinoctial ſphere of ſix feet diameter; an azimuthal horizon of ſix feet diameter; a large quadrant ſix feet radius; a ſextant eight feet radius; and a celeſtial globe ſix feet diameter.

Obſervatories, as they are very uſeful, and indeed abſolutely neceſſary for aſtronomers, ſo they have become more common than they were. There is a very excellent one now at Oxford, built by the truſtees of Dr Radcliffe, at the expence of nearly 30,000l. At Cambridge there is as yet no public obſervatory. Over the great gate of Trinity college, indeed, there is one which is called *Sir Iſaac Newton's*, becauſe this great philoſopher had uſed it; but it is gone to decay. It were well if the univerſity would repair and preſerve it in memory of that truly great man. In St John's, too, there is a ſmall one. The late ingenious Mr Cotes had uſed to give lectures in Sir Iſaac Newton's on experimental philoſophy. There are ſeveral very good ones in the Scotch univerſities; and there is an excellent one lately erected at Dublin.

Plate CCCXLVIII.

5. Bramins obſervatory at Benares. Of this Sir Robert Barker gives the following account, (Phil. Tranſ. Vol. LXVII. p. 598.) "Benares in the Eaſt Indies, one of the principal ſeminaries of the Bramins or prieſts of the original Gentoos of Hindoſtan, continues ſtill to be the place of reſort of that ſect of people; and there are many public charities, hoſpitals, and pagodas, where ſome thouſands of them now reſide. Having frequently heard that the ancient Bramins had a knowlege of aſtronomy, and being confirmed in this by their information of an approaching eclipſe both of the ſun and moon, I made inquiry, when at that place in the year 1772, among the principal Bramins, to endeavour to get ſome information relative to the manner in which they were acquainted of an approaching eclipſe. The moſt intelligent that I could meet with, however, gave me but little ſatisfaction. I was told, that theſe matters were confined to a few, who were in poſſeſſion of certain books and records; ſome containing the my-

ſteries of their religion; and others the tables of aſtronomical obſervations, written in the Shanſcrit language, which few underſtood but themſelves: that they would take me to a place which had been conſtructed for the purpoſe of making ſuch obſervations as I was inquiring after, and from whence they ſuppoſed the learned Bramins made theirs. I was then conducted to an ancient building of ſtone, the lower part of which, in its preſent ſituation, was converted into a ſtable for horſes, and a receptacle for lumber; but, by the number of court-yards and apartments, it appeared that it muſt once have been an edifice for the uſe of ſome public body of people. We entered this building, and went up a ſtaireaſe to the top of a part of it, near to the river Ganges, that led to a large terrace, where, to my ſurpriſe and ſatisfaction, I ſaw a number of inſtruments yet remaining, in the greateſt preſervation, ſtupendouſly large, immoveable from the ſpot, and built of ſtone, ſome of them being upwards of 20 feet in height; and although they are ſaid to have been erected 200 years ago, the graduated diviſions on the ſeveral arcs appeared as well cut, as accurately divided, as if they had been the performance of a modern artiſt. The execution in the conſtruction of theſe inſtruments exhibited a mathematical exactneſs in the fixing, bearing, fitting of the ſeveral parts, in the neceſſary and ſufficient ſupports to the very large ſtones that compoſed them, and in the joining and faſtening each into the other by means of lead and iron.

"The ſituation of the two large quadrants of the inſtrument marked A in the plate, whoſe radius is nine feet two inches, by their being at right angles with a gnomon at twenty-five degrees elevation, are thrown into ſuch an oblique ſituation as to render them the moſt difficult, not only to conſtruct of ſuch a magnitude, but to ſecure in their poſition for ſo long a period, and affords a ſtriking inſtance of the ability of the architect in their conſtruction: for, by the ſhadow of the gnomon thrown on the quadrants, they do not appear to have altered in the leaſt from their original poſition; and ſo true is the line of the gnomon, that, by applying the eye to a ſmall iron ring of an inch diameter at one end, the ſight is carried through three others of the ſame dimenſion, to the extremity at the other end, diſtant 38 feet 8 inches, without obſtruction; ſuch is the firmneſs and art with which this inſtrument has been executed. This performance is the more wonderful and extraordinary when compared with the works of the artificers of Hindoſtan at this day, who are not under the immediate direction of an European mechanic; but arts appear to have declined equally with ſcience in the eaſt.

"Lieutenant Colonel Archibald Campbell, at that time chief engineer in the Eaſt India Company's ſervice at Bengal, made a perſpective drawing of the whole of the apparatus that could be brought within his eye at one view; but I lament he could not repreſent ſome very large quadrants, whoſe radii were about twenty feet, they being on the ſide from whence he took his drawing. Their deſcription however is, that they are exact quarters of circles of different radii, the largeſt of which I judged to be 20 feet, conſtructed very exactly on the ſides of ſtone walls, built perpendicular, and ſituated, I ſuppoſe, in the meridian of the place: a braſs pin is fixed at the centre or angle of the quadrant, from whence, the Bramin informed me, they ſtretched a wire to the circumference when an obſervation was to be made; from which, it occurred to me, the obſerver muſt have moved his eye up or down the circumference, by means of a ladder or ſome ſuch contrivance, to raiſe and lower himſelf, until he had diſcovered the altitude of any of the heavenly bodies in their paſſage over the meridian, ſo expreſſed on the arcs of theſe quadrants: theſe arcs were very exactly divided into nine large ſections; each of which again into ten, making ninety leſſer diviſions or degrees; and thoſe alſo into twenty, expreſſing three minutes each, of about two-tenths of an inch aſunder; ſo that it is probable they had ſome method of dividing even theſe into more minute diviſions at the time of obſervation.

"My time would only permit me to take down the particular dimenſions of the moſt capital inſtrument, or the greater equinoctial ſun dial, repreſented by figure A, which appears to be an inſtrument to expreſs ſolar time by the ſhadow of a gnomon upon two quadrants, one ſituated to the eaſt, and the other to the weſt of it; and indeed the chief part of their inſtruments at this place appear to be conſtructed for the ſame purpoſe, except the quadrants, and a braſs inſtrument that will be deſcribed hereafter.

"Figure B is another inſtrument for the purpoſe of determining the exact hour of the day by the ſhadow of a gnomon, which ſtands perpendicular to, and in the centre of, a flat circular ſtone, ſupported in an oblique ſituation by means of four upright ſtones and a croſs piece; ſo that the ſhadow of the gnomon, which is a perpendicular iron rod, is thrown upon the diviſion of the circle deſcribed on the face of the flat circular ſtone.

"Figure C is a braſs circle, about two feet diameter, moving vertically upon two pivots between two ſtone pillars, having an index or hand turning round horizontally on the centre of this circle, which is divided into 360 parts; but there are no counter diviſions on the index to ſubdivide thoſe on the circle. This inſtrument appears to be made for taking the angle of a ſtar at ſetting or riſing, or for taking the azimuth or amplitude of the ſun at riſing or ſetting.

"The uſe of the inſtrument, figure D, I was at a loſs to account for. It conſiſts of two circular walls; the outer of which is about forty feet diameter, and eight feet high; the wall within about half that height, and appears intended for a place to ſtand on to obſerve the diviſions on the upper circle of the outer wall, rather than for any other purpoſe; and yet both circles are divided into 360 degrees, each degree being ſubdivided into twenty leſſer diviſions, the ſame as the quadrants. There is a door-way to paſs into the inner circle, and a pillar in the centre, of the ſame height with the lower circle, having a hole in it, being the centre of both circles, and ſeems to be a ſocket for an iron rod to be placed perpendicular into it. The diviſions on theſe, as well as all the other inſtruments, will bear a nice examination with a pair of compaſſes.

"Figure E is a ſmaller equinoctial ſun dial, conſtructed upon the ſame principle as the large one A.

"I cannot quit this ſubject without obſerving, that the Bramins, without the aſſiſtance of optical glaſſes, moſt conſiderable: the Tom falls into it in Lat. 58. and the Irtis in Lat. 61. and Long. 86. The exact courſe of this river was unknown till the country was ſurveyed by the Ruſſians; who have given us tolerable maps of it and of all Siberia. The Oby forms the boundary between Europe and Aſia, and its courſe is upwards of 2000 miles in length.

OCCIDENT, in geography, the weſtward quarter of the horizon; or that part of the horizon where the ecliptic, or the ſun therein, deſcends into the lower hemiſphere; in contradiſtinction to *orient*. Hence we uſe the word *occidental* for any thing belonging to the weſt; as occidental bezoar, occidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the ſkull.

OCCULT, ſomething hidden, ſecret, or inviſible. The occult ſciences are magic, necromancy, cabbala, &c. Occult qualities, in philoſophy, were thoſe qualities of body or ſpirit which baffled the inveſtigation of philoſophers, and for which they were unable to give any reaſon; unwilling however to acknowledge their ignorance, they deceived themſelves and the vulgar by an empty title, calling what they did not know *occult*.

OCCULT, in geometry, is uſed for a line that is ſcarce perceivable, drawn with the point of the compaſſes or a leaden pencil. Theſe lines are uſed in ſeveral operations, as the raiſing of plans, deſigns of building, pieces of perſpective, &c. They are to be effaced when the work is finiſhed.

OCCULTATION, in aſtronomy, the time a ſtar or planet is hid from our ſight, by the interpoſition of the body of the moon or ſome other planet.

OCCUPANCY, in law, is the taking poſſeſſion of thoſe things which before belonged to nobody. This is the true ground and foundation of all PROPERTY, or of holding thoſe things in ſeveralty, which by the law of nature, unqualified by that of ſociety, were common to all mankind. But, when once it was agreed that every thing capable of ownerſhip ſhould have an owner, natural reaſon ſuggeſted, that he who could firſt declare his intention of appropriating any thing to his own uſe, and, in conſequence of ſuch his intention, actually took it into poſſeſſion, ſhould thereby gain the abſolute property of it; according to that rule of the law of nations, recognized by the laws of Rome, *Quod nullius eſt, id ratione naturali occupanti conceditur*.

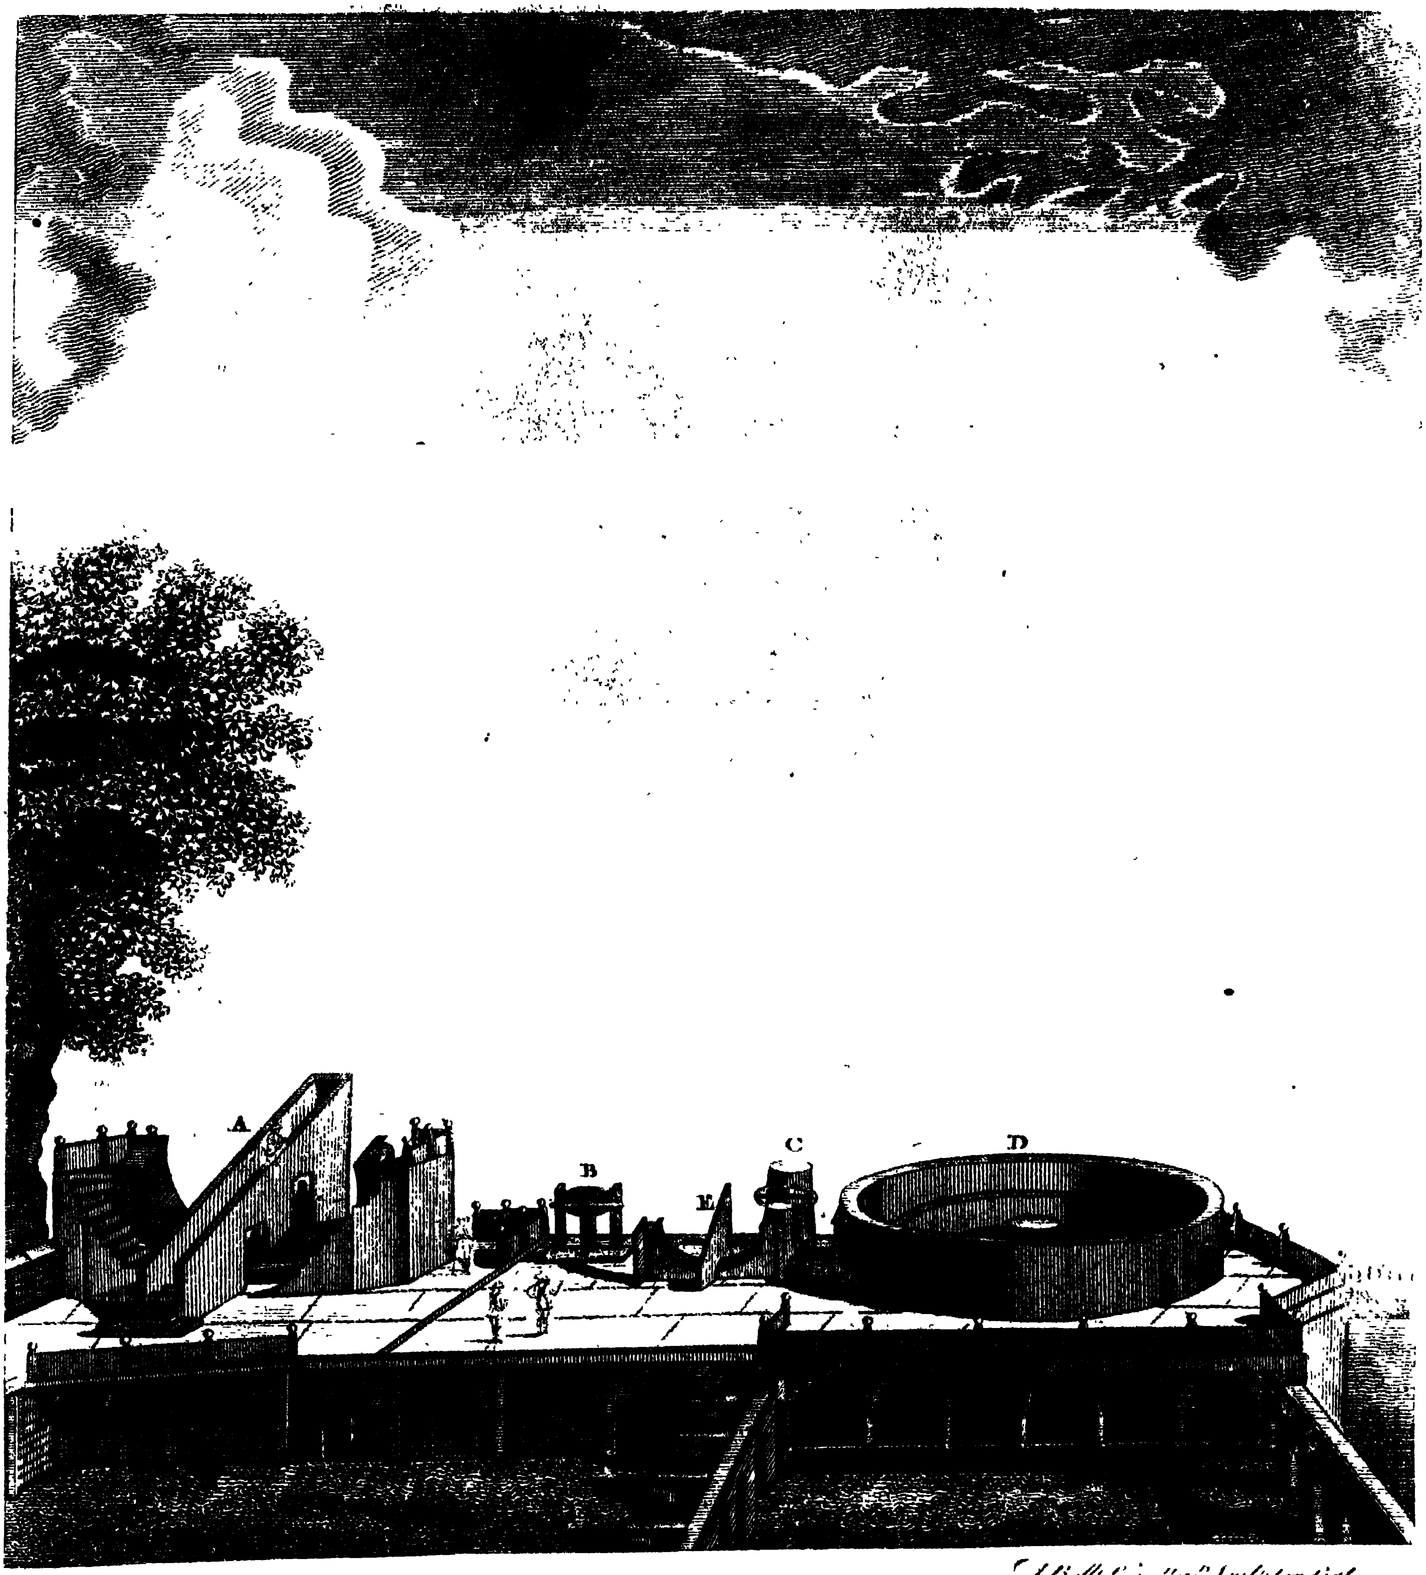
Blackſt. Comment.

This right of occupancy, ſo far as it concerns real property, hath been confined by the laws of England within a very narrow compaſs; and was extended only to a ſingle inſtance; namely, where a man was tenant *pour autre vie*, or had an eſtate granted to himſelf only (without mentioning his heirs) for the life of another man, and died during the life of *ceſtuy que vie*, or him by whoſe life it was holden: in this caſe, he that could firſt enter on the land, might lawfully retain the poſſeſſion ſo long as *ceſtuy que vie* lived, by right of occupancy.

This ſeems to have been recurring to firſt principles, and calling in the law of nature to aſcertain the property of the land, when left without a legal owner. For it did not revert to the granter, who had parted with all his intereſt, ſo long as *ceſtuy que vie* lived; it

did

Bramin's OBSERVATORY. Plate CCCXLVIII



A. Bell Prin. Wal. Sculptor fecit.

did not eſcheat to the lord of the fee ; for all eſcheats muſt be of the abſolute entire fee, and not of any particular eſtate carved out of it, much leſs of ſo minute a remnant as this : it did not belong to the grantee ; for he was dead : it did not deſcend to his heirs ; for there were no words of inheritance in the grant : nor could it veſt in his executors ; for no executors could ſucceed to a freehold. Belonging therefore to nobody, like the *hæreditas jacens* of the Romans, the law left it open to be ſeized and appropriated by the firſt perſon that could enter upon it, during the life of *ceſtuy que vie*, under the name of an occupant. But there was no right of occupancy allowed, where the king had the reverſion of the lands : for the reverſioner hath an equal right with any other man to enter upon the vacant poſſeſſion ; and where the king's title and a ſubject's interfere, the king's ſhall always be preferred. Againſt the king therefore there could be no prior occupant, becauſe *nullum tempus occurrit regi*. And, even in the caſe of a ſubject, had the eſtate *pour autre vie* granted to a man *and his heirs* during the life of *ceſtuy que vie*, there the heir might, and ſtill may, enter and hold poſſeſſion, and is called in law a *ſpecial occupant* ; as having a ſpecial excluſive right, by the terms of the original grant, to enter upon and occupy this *hæreditas jacens*, during the reſidue of the eſtate granted ; though ſome have thought him ſo called with no very great propriety ; and that ſuch eſtate is rather a deſcendible freehold. But the title of *common occupancy* is now reduced almoſt to nothing by two ſtatutes ; the one, 29 Car. II. c. 3. which enacts, that where there is no ſpecial occupant, in whom the eſtate may veſt, the tenant *pour autre vie* may deviſe it by will, or it ſhall go to the executors, and be aſſets in their hands for payment of debts : the other that of 14 Geo. II. c. 20. which enacts, that it ſhall veſt not only in the executors, but, in caſe the tenant dies inteſtate, in the adminiſtrators alſo ; and go in courſe of a diſtribution like a chattel intereſt.

By theſe two ſtatutes the title of *common occupancy* is utterly extinct and aboliſhed : though that of *ſpecial occupancy*, by the heir at law, continues to this day ; ſuch heir being held to ſucceed to the anceſtor's eſtate, not by deſcent, for then he muſt take an eſtate of inheritance, but as an occupant, ſpecially marked out and appointed by the original grant. The doctrine of common occupancy may, however, be uſefully remembered on the following account, amongſt others : That, as by the common law no occupancy could be of incorporeal hereditaments, as of rents, tithes, advowſons, commons, or the like, (becauſe, with reſpect to them, there could be no actual entry made, or corporal ſeiſin had ; and therefore by the death of the grantee *pour autre vie* a grant of ſuch hereditaments was entirely determined) : ſo now, it is apprehended, notwithſtanding thoſe ſtatutes, ſuch grant would be determined likewiſe ; and the hereditaments could not be deviſable, nor veſt in the executors, nor go in a courſe of diſtribution. For the ſtatutes muſt not be conſtrued ſo as to create any new eſtate, or to keep that alive which by the common law was determined, and thereby to defeat the granter's reverſion ; but merely to diſpoſe of an intereſt in being, to which by law there was no owner, and which therefore was left open to the firſt occupant. When there is a reſidue left, the ſtatutes give it to the executors, &c. inſtead of the firſt occupant ; but they will not create a reſidue on purpoſe to give it to the executors. They only mean to provide an appointed inſtead of a caſual, a certain inſtead of an uncertain, owner, of lands which before were nobody's ; and thereby to ſupply this *caſus omiſſus*, and render the diſpoſition of the law in all reſpects entirely uniform ; this being the only inſtance wherein a title to a real eſtate could ever be acquired by occupancy.

For there can be no other caſe deviſed, wherein there is not ſome owner of the land appointed by the law. In the caſe of a ſole corporation, as a parſon of a church, when he dies or reſigns, though there be no *actual* owner of the land till a ſucceſſor be appointed, yet there is a *legal, potential*, ownerſhip, ſubſiſting in contemplation of law ; and when the ſucceſſor is appointed, his appointment ſhall have a retroſpect and relation backwards, ſo as to entitle him to all the profits from the inſtant that the vacancy commenced. And, in all other inſtances, when the tenant dies inteſtate, and no other owner of the lands is to be found in the common courſe of deſcents, there the law veſts an ownerſhip in the king, or in the ſubordinate lord of the fee, by eſcheat.

So alſo, in ſome caſes, where the laws of other nations give a right by occupancy, as in lands newly created, by the riſing of an iſland in a river, or by the alluvion or dereliction of the ſea ; in theſe inſtances, the law of England aſſigns them an immediate owner. For Bracton tells us, that if an iſland ariſe in the *middle* of a *river*, it belongs in common to thoſe who have lands on each ſide thereof ; but if it be nearer to one bank than the other, it belongs only to him who is proprietor of the neareſt ſhore : which is agreeable to, and probably copied from, the civil law. Yet this ſeems only to be reaſonable, where the ſoil of the river is equally divided between the owners of the oppoſite ſhores : for if the whole ſoil is the freehold of any one man, as it muſt be whenever a ſeveral fiſhery is claimed, there it ſeems juſt (and ſo is the uſual practice) that the iſlets, or little iſlands, ariſing in any part of the river, ſhall be the property of him who owneth the piſcary and the ſoil. However, in caſe a new iſland riſe in the *ſea*, though the civil law gives it to the firſt occupant, yet our's gives it to the king. And as to lands gained from the ſea ; either by *alluvion*, by the waſhing up of ſand and earth, ſo as in time to make *terra firma* ; or by *dereliction*, as when the ſea ſhrinks back below the uſual water mark ; in theſe caſes the law is held to be, that if this gain be by little and little, by ſmall and imperceptible degrees, it ſhall go to the owner of the land adjoining. For *de minimis non curat lex* : and, beſides, theſe owners being often loſers by the breaking in of the ſea, or at charges to keep it out, this poſſible gain is therefore a reciprocal conſideration for ſuch poſſible charge or loſs. But if the alluvion or dereliction be ſudden and conſiderable, in this caſe it belongs to the king : for, as the king is lord of the ſea, and ſo owner of the ſoil while it is covered with water, it is but reaſonable he ſhould have the ſoil when the water has left it dry. So that the quantity of ground gained, and the time during which it is gained, are what make it either the king's or the ſubject's property. In the ſame manner, if a river, running between two lordſhips, by degrees gains upon the one, and thereby leaves the other dry; the owner who loſes his ground thus imperceptibly has no remedy: but if the courſe of the river be changed by a ſudden and violent flood, or other haſty means, and thereby a man loſes his ground, he ſhall have what the river has left in any other place as recompenſe for this ſudden loſs. And this law of alluvions and dereliĉtions, with regard to *rivers*, is nearly the ſame in the imperial law; from whence indeed thoſe our determinations ſeem to have been drawn and adopted: but we ourſelves, as iſlanders, have applied them to *marine* increaſes; and have given our ſovereign the prerogative he enjoys, as well upon the particular reaſons before mentioned, as upon this other general ground of prerogative, which was formerly remarked, that whatever hath no other owner is veſted by law in the king. See PREROGATIVE.

OCCUPANT, in law, the perſon that firſt ſeizes or gets poſſeſſion of a thing.

OCCUPATION, in a legal ſenſe, is taken for uſe or tenure: as in deeds it is frequently ſaid, that ſuch lands are, or were lately, in the tenure or occupation of ſuch a perſon.—It is likewiſe uſed for a trade or myſtery.

OCCUPIERS *of* WALLING, a term uſed in the ſaltworks for the perſons who are the ſworn officers that allot in particular places what quantity of ſalt is to be made, that the markets may not be overſtocked, and ſee that all is carried fairly and equally between the lord and the tenant.

OCEAN, that huge maſs of ſalt waters which encompaſſes all parts of the globe, and by means of which, in the preſent improved ſtate of navigation, an eaſy intercourſe ſubſiſts between places the moſt diſtant.

The ocean is diſtinguiſhed into three grand diviſions. 1. The Atlantic ocean, which divides Europe and Africa from America, which is generally about 3000 miles wide. 2. The Pacific ocean, or South ſea, which divides America from Aſia, and is generally about 10,000 miles over. And, 3. The Indian ocean, which ſeparates the Eaſt Indies from Africa: which is 3000 miles over. The other ſeas, which are called *oceans*, are only parts or branches of theſe, and uſually receive their names from the countries they border upon.

For the ſaltneſs, tides, &c. of the ocean, ſee the articles SEA, TIDES, &c.

OCEANIDES (fab. hiſt.), ſea nymphs, daughters of Oceanus, from whom they received their name, and of the goddeſs Tethys or Thetis. They were 3000 according to Apollodorus, who mentions the names of ſeven of them; Aſia, Styx, Eleĉtra, Donis, Eurynome, Amphitrite, and Metis. Heſiod ſpeaks of the eldeſt of them, which he reckons 41, Pitho, Admete, Prynno, Ianthe, Rhodia, Hippo, Callirhoe, Urania, Clymene, Idyia, Paſithoe, Clythia, Zeuxo, Galuxaure, Plexaure, Perſeis, Pluto, Thoe, Polydora, Meloboſis, Dione, Cerceis, Xanthe, Acaſta, Ianira, Teleſtho, Europa, Meneſtho, Petræa, Eudora, Calypſo, Tyche, Ocyroe, Criſia, Amphiro, with thoſe mentioned by Apollodorus, except Amphitrite. Hyginus mentions 16 whoſe names are almoſt all different from thoſe of Apollodorus and Heſiod; which difference proceeds from the mutilation of the original text. The Oceanides, like the reſt of the inferior deities, were honoured with libations and ſacrifices. Prayers were offered to them, and they were entreated to proteĉt ſailors from ſtorms and dangerous tempeſts. The Argonauts, before they proceeded to their expedition, made an offering of flour, honey, and oil, on the ſea ſhore, to all the deities of the ſea, and ſacrificed bulls to them, and entreated their proteĉtion. When the ſacrifice was made on the ſea ſhore, the blood of the viĉtim was received in a veſſel; but when it was in open ſea, they permitted the blood to run down into the waters. When the ſea was calm, they generally offered a lamb or a young pig; but if it was agitated by the winds and rough, a black bull was deemed the moſt acceptable viĉtim.

OCEANUS, in Pagan mythology, the ſon of Cœlus and Terra, the huſband of Thetis, and the father of the rivers and fountains, called *Oceanides*. The ancients called him the *Father of all things*, imagining that he was produced by Humidity, which, according to Thales, was the firſt principle from which every thing was produced. Homer repreſents Juno viſiting him at the remoteſt limits of the earth, and acknowledging him and Thetis as the parents of the gods. He was repreſented with a bull's head, as an emblem of the rage and bellowing of the ocean when agitated by a ſtorm.

According to Homer, he was the father even of all the gods, and on that account he received frequent viſits from them. He is often, indeed almoſt always, repreſented as an old man with a long flowing beard, and ſitting upon the waves of the ſea. He often holds a pike in his hand, while ſhips under ſail appear at a diſtance, or a ſea monſter ſtands near him. Oceanus preſided over every part of the ſea, and even the rivers were ſubjeĉted to his power. The ancients were ſuperſtitious in their worſhip of him, and revered with great ſolemnity a deity to whoſe care they intruſted themſelves when going on any voyage.

OCEIA, a woman who preſided over the ſacred rites of Veſta for 57 years with the greateſt ſanctity. She died in the reign of Tiberius, and the daughter of Domitius ſucceeded her.

OCELLUS *the* LUCANIAN, an ancient Greek philoſopher of the ſchool of Pythagoras, who lived before Plato. His work περι του Παντος, or "The Univerſe," is the only piece of his which is come down entire to, and was written originally in the Doric dialeĉt, but was tranſlated by another hand into the Attic. William Chriſtian, and after him Lewis Nogarola, tranſlated this work into Latin; and we have ſeveral editions of it, both in Greek and Latin.

OCELOT, the Mexican cat. See FELIS.

OCELOXOCHITL, or TYGER-FLOWER, in botany: A large Mexican plant, compoſed of three pointed petals, red, but towards the middle of a mixed white and yellow, repreſenting in ſome degree the ſpots of that wild animal from which it takes its name. The plant has leaves alſo reſembling thoſe of the iris, and a bulbous root. See Plate CCCL.

OCHINUS (Bernardin), a celebrated Italian, was borne at Siene in 1487, and firſt became a Cordelier: but he quickly returned into the world, applied himſelf to the ſtudy of phyſic, and acquired the eſteem of Cardinal Julius de Medicis, afterwards Pope Clement VII. At length, again changing his mind, he reſumed ed his monk's habit in a penitential mood; and not content with this, but aiming at higher perfection, he embraced in 1534 the reformed ſect of the Capuchins. He practiſed, with a moſt rigorous exactneſs, all the rules of the order; which, being then in its infancy, he contributed ſo much to improve and enlarge, that ſome writers have called him the founder of it. He was certainly made vicar-general of it, and became in the higheſt degree eminent for his pulpit eloquence. He delivered his ſermons with ſo much grace and politeneſs, and ſpoke ſo copiouſly, that he raviſhed his audience wherever he was: never indeed was a man more ſucceſsful or more applauded. His extraordinary merit procured him the favour of Pope Paul III. who, it is ſaid, made him his father confeſſor, and preacher. He was thus the darling both of prince and people; when, falling into the company of one John Valde a Spaniard, who had imbibed Luther's doctrine in Germany, he became a proſelyte. He was then at Naples, and began to preach in favour of Proteſtantiſm; which being obſerved, he was ſummoned to appear at Rome; and was in his way thither when he met at Florence Peter Martyr, with whom, it is probable, he had become acquainted at Naples. • This friend perſuaded him not to put himſelf into the pope's power; and they both agreed to withdraw to ſome place of ſafety. Ochinus went firſt to Ferrara, where he diſguiſed himſelf in the dreſs of a ſoldier; and proceeding thence to Geneva, arrived there in 1542, and married a woman of Lucca. He did not, however, ſettle there, but went to Augſburg, where he publiſhed ſome ſer-

In 1547 he was invited, together with Peter Martyr, into England by Archbiſhop Cranmer, that he might have their joint aſſiſtance in carrying on the reformation. They arrived in December; and going to Lambeth, were kindly received by Cranmer. They were entertained there for ſome time; and Ochinus, as well as Martyr, was made a prebendary of Canterbury (A). He laboured heartily in the conduct of the reformation; and his dialogue upon the unjuſt uſurped primacy of the biſhop of Rome, was tranſlated into Latin by Ponet biſhop of Wincheſter, and publiſhed in 1549. But upon the death of Edward VI. being forced as well as Martyr to leave England, they retired to Straſburg, where they arrived in 1553. From this city Ochinus went to Baſil, and was invited thence in 1555 to Zurich, to be miniſter of an Italian church which was gathering there. This church conſiſted of ſome refugees from Locarno, one of the four bailiwicks which the Switzers poſſeſs in Italy; they being hindered from the public exerciſe of the reformed religion by the oppoſition of the Popiſh cantons. Ochinus had no difficulty to ſubſcribe the articles of faith agreed upon by the church of Zurich, and met in that city with Bullinger, who proved a very good friend to him. He governed this Italian church till 1563, when he was baniſhed thence by the magiſtrates of the town for publiſhing ſome dialogues, wherein he defended the doctrine of polygamy. From Zurich he went to Baſil; but not being ſuffered to ſtay there, he fled in great diſtreſs into Moravia, where he fell in with the Socinians, and joined them. Staniſlaus Lubienietſki, the great patron of this ſect, gives the following account of his laſt days in his *Hiſt. Reformat. Polon.* Ochinus, ſays he, retired into Moravia, and into Poland, and even there he was not out of the reach of Calvin's letters. He returned into Moravia after King Sigiſmund's edict; who in 1564 puniſhed with baniſhment all thoſe that were called Tritheiſts, Atheiſts, &c. Some gentlemen endeavoured to keep him in Poland; but he anſwered, that men muſt obey the magiſtrates, and that he would obey them, even were he to die among the wolves in the woods. During his travels, he fell ſick of the plague at Pinckſow, and received there all poſſible offices of kindneſs from one of the brethren, named Philippovius. His daughter and two ſons, whom he carried along with him, died of the plague; but he had buried his wife before he had left Zurich. As for himſelf, he continued his journey to Moravia, and within three weeks died at Slakow, in 1564, aged 77.

His character is various]y repreſented by different authors, as was to be expected; for men like him have all manner of things, good and bad, ſaid and written of them, by ſomebody or other. Bayle ſays, that the confeſſion he made publicly, on the change of his religion, is remarkable. He acknowledged, in a preface, that if he could have continued, without danger of his life, to preach the truth, after the manner he had preached it for ſome years, he would never have laid down the habit of his order; but as he did not find himſelf that courage which is requiſite to undergo martyrdom, he took ſanctuary in a Proteſtant country. His writings are numerous but not bulky.

OCHLOCRACY, that form of government wherein the populace have the chief adminiſtration of affairs.

OCHNA, in botany: A genus of the *monogynia* order, belonging to the polyandria claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The corolla is pentapetalous; the calyx pentaphyllous; the berries monoſpermous, and affixed to a large roundiſh receptacle.

OCHRE, in natural hiſtory, a genus of earths, ſlightly coherent, and compoſed of fine, ſmooth, ſoft, argillaceous particles, rough to the touch, and readily diffuſible in water. Ochres are of various colours, as red, blue, yellow, brown, green, &c.

OCHROMA, in botany: A genus of the pentandria order, belonging to the monodelphia claſs of plants; and in the natural method ranking under the 37th order, *Columniferæ*. The corolla conſiſts of ſix petals, three of which are external, and the other three internal; the antheræ unite and form a ſpiral pillar round the ſtyle; the capſule is long, and has five loculaments, and contains a number of black round ſeeds. Of this there is only one ſpecies, viz. the ochroma lagopus, the downtree or corkwood. This tree is frequent in Jamaica, is of ſpeedy growth, and riſes to about 25 or 30 feet. The flowers are large and yellow. The capſules are about five inches long, round-

---

(A) According to Wood, Athen. Oxon. but it reſts ſolely on his authority, ſo far as we know.

ed, and covered with a thin ſkin; which when dry falls off in five longitudinal ſegments, and leaves the fruit greatly reſembling a hare's foot. The down is ſhort, ſoft, and ſilky: it is uſed ſometimes to ſtuff beds and pillows; but, like other vegetable downs, is apt to get into clots: an inſipid clear gum exudes from the tree when wounded. The bark is tough, and its fibres are in a reticulated form: it might be made into ropes. The dried wood is ſo very light and buoyant, as to be uſed by the fiſhermen in Jamaica for their nets inſtead of pieces of cork.

OCHUS, a king of Perſia, ſon of Artaxerxes. He was cruel and avaricious; and in order to ſtrengthen himſelf on his throne, he murdered all his brothers and ſiſters. His ſubjects revolted; but he reduced them to obedience, and added Egypt to his other dominions. Bagoas his favourite eunuch poiſoned him for the inſults he had offered to Apis the god of the Egyptians; and he gave his fleſh to be eaten by cats, and made handles for knives with his bones. It ſeems to be not a little remarkable, that all thoſe monſters who diſgraced humanity by their crimes, and ſunk themſelves below the level of brutes, have met with condign puniſhment; and this in general ſeems true, whether we refer to ancient or modern times.—A man of Cyzicus, who was killed by the Argonauts.—A prince of Perſia, who refuſed to viſit his native country for fear of giving all the women each a piece of gold.—A river of India or of Bactriana.—A king of Perſia: He exchanged this name for that of Darius Nothus. See Perſia.

OCKHAM, Occam, or Occham (William of), was a celebrated ſcholaſtic divine in the 14th century, of the order of Cordeliers. He was a native of England, and diſciple to the famous Duns Scotus. He was head of the Nominaliſts: and acquired ſo much celebrity, as to be denominated the *Invincible Doctor*.

At the requeſt of Michael de Ceſena, general of his order, he became a party man with Lewis of Raviere, who was an avowed enemy of the church of Rome; and he really wrote vigorouſly againſt Pope John XXII. and his ſucceſſors. Trithemius informs us, that he uſed to ſay to Lewis, "My Lord, let your ſword defend me, and my pen ſhall be always ready to ſupport you." He treated Charles and Clement in a book he wrote againſt them with a groſs ſcurrility.

This, however, was a bold, dangerous, and imprudent ſtep, and cannot well be defended on any proper principle. The effect of it, as might be expected, was an accuſation againſt him and Ceſena. They were charged with maintaining, that neither Chriſt nor his apoſtles had any poſſeſſions at all, either in common or as private property. This doctrine gave riſe to that pleaſant queſtion called the *bread of the Cordeliers;* and conſiſted in determining, whether the dominion of things conſumed in the uſe, ſuch as bread and wine, belonged to them, or only the ſimple uſe of them, without the dominion? Their rule not permitting them to have any thing as property, Pope Nicolas III. who had been of their order, deviſed a method to enrich them, without breaking their rule. To this end he made an ordinance, that they ſhould have only the uſufruct of the eſtates which ſhould be given to them, and that the ſoil and fund of all ſuch donations ſhould belong to the Roman church at large. By this means he gave them the poſſeſſion of an almoſt infinite number of eſtates, in the name of the church of Rome: but on this account, Pope Nicolas's bull was revoked by John XXII. who condemned the uſe without the dominion, by his *Extravaganta ad Conditorem.* He alſo condemned, by another *Extravaganta cum inter*, the doctrine about the poſſeſſion of eſtates by Chriſt and his apoſtles. Ockham and Ceſena were alſo excommunicated, becauſe they had departed from Avignon without the pope's licenſe, and had written againſt him. Ockham, however, was abſolved, as is ſaid, from this cenſure before he died, which was about the year 1347.

We have ſeveral pieces of his, which are written with conſiderable wit and ſubtility. The reformed church ſometimes makes uſe of his reaſoning againſt the church of Rome. Melchior Goldaſt printed, in his treatiſe upon monarchy, 415 queſtions of Ockham. His works are mentioned by many authors.

OCKLEY (Simon), a learned orientaliſt, was born at Exeter in 1678, and educated at Queen's college, Cambridge, where he diſtinguiſhed himſelf by his intenſe application to literature. At the uſual time he took the degrees in arts, and that of bachelor in divinity; but marrying very young, was precluded from a fellowſhip in his college, and this occaſioned his being afterwards involved in many difficulties. In 1705, he was preſented to the vicarage of Swaveſey in Cambridgeſhire; and in 1711 he was choſen Arabic profeſſor of the univerſity. He was perfect maſter of the Arabic and other oriental tongues: the learned Reland ſaid of him. Vir, ſi quis alius harum literarum peritus." Afterwards, however, he had the misfortune to be confined for ſome time in Cambridge caſtle for debt. The above preferments, notwithſtanding, he enjoyed till his death, which happened on the 9th of Auguſt 1720. He wrote, 1. *Introductio ad Linguas Orientales*. 2. The hiſtory of the preſent Jews throughout the world; tranſlated from the Italian of Leo Modena, a Venetian rabbi. 3. The improvement of human reaſon, exhibited in the life of Hai Ebn Yokdhan, tranſlated from the Arabic. 4. An account of South-weſt Barbary, containing what is moſt remarkable in the kingdoms of Fez and Morocco; written by a perſon who had been a ſlave there a conſiderable time, and tranſlated from his manuſcript. 5. The hiſtory of the Saracens, collected from the moſt authentic Arabic authors, in 2 vols. 8vo. He was not only well ſkilled in the learned languages, but alſo in the modern, as French, Spaniſh, Italian, &c.

OCRA, a viſcous vegetable ſubſtance well known in the Weſt Indies, where it is uſed to thicken ſoup, and for other purpoſes.

OCRISIA (fab. hiſt.), the wife of Corniculus, was one of the attendants of Tanaquil the wife of Tarquinius Priſcus. As ſhe was throwing into the flames for offerings ſome of the meats that were ſerved on the table of Tarquin, ſhe ſuddenly ſaw, as is reported, in the fire what Ovid calls *obſcæni forma virilis*. She informed the queen of it; and when by her command ſhe had approached near it, ſhe conceived a ſon who was named Servius Tullius, and was educated in the king's family. He afterwards ſucceeded to the vacant throne. Some ſuppoſe that Vulcan had aſſumed that form which was preſented to the eyes of Ocriſia, and that this god was the father of the ſixth king of Rome.

OCTAETERIS, a cycle or term of eight years, in the Grecian chronology, at the concluſion of which three entire lunar months were added. This cycle was in uſe till Meton's invention of the golden number or cycle of 19 years.

OCTAGON, or Octogon, in geometry, is a figure of eight ſides and angles; and this, when all the ſides and angles are equal, is called a *regular octagon*, or one that may be inſcribed in a circle.

Octagon, in fortification, denotes a place that has eight baſtions. See Fortification.

OCTAHEDRON, or Octaedron, in geometry, one of the five regular bodies, conſiſting of eight equal and equilateral triangles.

OCTANDRIA (*οκτω* " eight," and *ανηρ* a " man, or huſband,") the 8th claſs in Linnæus's ſexual ſyſtem; conſiſting of plants with hermaphrodite flowers, which are furniſhed with eight ſtamina, or male organs of generation. See Botany, p. 430.

OCTANT, or Octile, in aſtronomy, that aſpect of two planets, wherein they are diſtant an eighth part of a circle, or 45° degrees from each other.

OCTAPLA, in matters of ſacred literature, denotes a Polyglot Bible, conſiſting of eight columns, and as many different verſions of the ſacred text; viz. the original Hebrew both in Hebrew and Greek characters, Greek verſions, &c.

OCTATEUCH, an appellation given to the eight firſt books of the Old Teſtament.

OCTAVE, in muſic. See Interval.

OCTAVIA, daughter of Caius Octavius and ſiſter to Auguſtus Cæſar. See the following article. She was one of the moſt illuſtrious ladies of ancient Rome; her virtues and her beauty were equally conſpicuous.—Prideaux ſays ſhe was much handſomer than Cleopatra. She married Claudius Marcellus, and after his death M. Antony. Her marriage with Antony was a political match, to reconcile her brother and him together. Antony proved for ſome time attentive to her: but when he had ſeen Cleopatra, he neglected and deſpiſed her; and when ſhe attempted to withdraw him from this illegal amour by going to meet him at Athens, ſhe was rebuked and totally baniſhed from his preſence. This affront was highly reſented by her brother; and though Octavia endeavoured to pacify him by palliating Antony's behaviour, yet he reſolved to revenge her cauſe by arms. After the battle of Actium and the death of Antony, Octavia, forgetful of her own injuries, took into her houſe all the children of her huſband, and treated them with extraordinary tenderneſs. Marcellus, her ſon by her firſt huſband, was married to a niece of Auguſtus, and openly intended as a ſucceſſor to his uncle. His ſudden death plunged all the family into the greateſt grief. Virgil, whom Auguſtus patronized, undertook of himſelf to pay a melancholy tribute to the memory of a young man whom Rome had looked upon as her future father and patron. He was deſired to repeat his compoſition in the preſence of the emperor and his ſiſter. Octavia burſt into tears even when the poet began; but when he mentioned *Tu Marcellus eris*, ſhe ſwooned away. This tender and pathetic encomium upon the merit and the virtues of young Marcellus ſhe liberally rewarded, and Virgil received 10,000 ſeſterces, according to ſome 78l. 2s. 6d. for every one of the verſes. Octavia had two daughters by Antony, Antonia Major and Antonia Minor.—The elder married L. Domitius Ahenobarbus, by whom ſhe had Cn. Domitius, who was the father of the emperor Nero by Agrippina the daughter of Germanicus. Antonia Minor, who was as virtuous and as beautiful as her mother, married Druſus the ſon of Tiberius, by whom ſhe had Germanicus and Claudius, who reigned before Nero. The death of Marcellus conſtantly preyed upon the mind of Octavia, who died of grief or melancholy, about 11 years before the Chriſtian era. Her brother paid great regard to her memory, and pronounced her funeral oration himſelf. The Roman people alſo ſhowed their regard to her virtues, by wiſhing to pay her divine honours.—A daughter of the emperor Claudius by Meſſalina. She was betrothed to Silanus, but by the intrigues of Agrippina, ſhe was married to the emperor Nero in the 16th year of her age. She was ſoon after divorced under pretence of barrenneſs; and the emperor married exerciſed her enmity upon Octavia by to be baniſhed into Campania. She recalled by the people; but Poppæa, rmined on her ruin, cauſed her again to to an iſland, where ſhe was ordered to kill pening her veins. Her head was cut off Poppæa.

IANUS, or Octavius Cæsar, was ne- lius Cæſar the dictator, being the ſon of Accia his ſiſter, by Octavius a ſenator, and afterwards became the ſecond emperor of Rome. He was born in the year of the city 691, during the conſulſhip of Cicero. His uncle Julius Cæſar adopted him, and left him the greateſt part of his fortune. When he was but 20 years of age, he was raiſed to the conſulſhip. His youth and inexperience were ridiculed by his enemies; notwithſtanding which obſtacle, his prudence and valour raiſed his conſequence. He made war againſt his opponents on pretence of avenging the aſſaſſination of his uncle. He engaged in five civil wars with great ſucceſs, viz. The wars of Mutina, Peruſia, Philippi, Sicily, and Actium: the firſt and laſt of which were againſt M. Antony; the ſecond againſt L. Antony, brother of the triumvir; the third was againſt Brutus and Caſſius; and the fourth againſt Sext. Pompey, ſon of Pompey the Great. He united his forces with Antony's at the battle of Philippi; and had he not been ſupported by the activity and bravery of his colleague, he would doubtleſs have been totally ruined in that engagement. In this triumvirate with Antony and Lepidus, he obtained the weſtern parts of the Roman empire; and, like his other colleagues, more firmly to eſtabliſh his power, he proſcribed his enemies and cut them off. The triumvirate laſted for 10 years. He had given his ſiſter Octavia in marriage to Antony, to make their alliance more laſting; but when Cleopatra had charmed this unfortunate man, Octavia was repudiated. Auguſtus immediately took up arms to avenge the wrongs of his ſiſter; but perhaps more eager to remove a man whoſe power and exiſtence kept him in continual fear and conſtant dependence. Both parties met at Actium to decide the fate of Rome. Antony was ſupported by all the power of the eaſt, and Auguſtus by Italy. Cleopatra fled from the battle with 60 ſhips; and her flight ruined the intereſt of Antony, who followed her into Egypt. The conqueror ſoon after went into Egypt likewiſe, beſieged Alexandria, and honoured with a magnificent funeral his unfortunate colleague and the celebrated queen, whom the fear of being led in the victor's triumph at Rome had driven to commit ſuicide. After he had eſtabliſhed peace all over the world, he ſhut the gates of the temple of Janus, A. U. C. 753. He was twice determined to lay down the ſupreme power immediately after the victory obtained over Antony, and on account of his ill health; but his two faithful friends Mecænas and Agrippa diſſuaded him, and contended, that if he did he would leave it to be the prey of the moſt powerful, and expoſe himſelf to the greateſt dangers. He died at Nola in the 76th year of his age, after he had held the ſovereign power for 57 years.—He was an active emperor, and conſulted the good of the Romans with the greateſt anxiety and care. He viſited all the provinces except Africa and Sardinia, and his conſummate prudence and experience occaſioned many ſalutary laws. He is, ho[illegible]er, accuſed of licentiouſneſs and adultery; [illegible] goodneſs of his heart, the fidelity of his frien[illegible] and the many good qualities which the poets whom [illegible]ronized have perhaps truly celebrated, ma[illegible] though in the eye of ſtrict religion and true [illegible]ty but little, amends for his natural foibles. He was ambitious of being eſteemed handſome; and as he was publicly reported to be the ſon of Apollo according to his mother's declaration, he wiſhed his flatterers to repreſent him with the figure and attributes of that god. Like Apollo, his eyes were clear, and he affected to have it thought that they poſſeſſed ſome divine irradiation, and was well pleaſed if, when he fixed his eyes upon any body, they held down their eyes as if overcome by the glaring brightneſs of the ſun. He diſtinguiſhed himſelf by his learning; he was a complete maſter of the Greek language, and wrote ſome tragedies, beſides memoirs of his life and other works, which are now loſt. He married four times; but he was unhappy in all theſe connexions; and his only daughter Julia diſgraced herſelf and her father by the debauchery and licentiouſneſs of her manners. He recommended at his death his adopted ſon Tiberius as his ſucceſſor. He left his fortune partly to him and to Druſus, and made donations to the army and Roman people. The title of Auguſtus was conferred upon him by the ſenate after the battle of Actium and the final deſtruction of the Roman republic. The title continued afterwards, being given to his ſucceſſors in the empire. Virgil is ſaid to have written his Æneid at the deſire of Auguſtus, whom he repreſents under the amiable and perfect character of Æneas. The name of Octavius was very common at Rome; it was the name of a variety of men of very conſiderable rank.

OCTOBER, in chronology, the eighth month of Romulus's year, which the name implies; but tenth in the kalendar of Numa, Julius Cæſar, &c. The ſenate gave this month the name *Fauſtinus*, in compliment to Fauſtina, the wife of the emperor Antoninus; Commodus would have it called *Invictus*; and Domitian named it *Domitianus*; but in ſpite of all theſe attempts it ſtill retains its original name. This month was ſacred to Mars, and under his protection.

October Equus, a horſe annually ſacrificed to Mars in the month of October, either becauſe the horſe is a warlike animal, or to puniſh him for the taking of Troy. A race was run with chariots, drawn by two horſes, previous to the ſacrifices, and he that ran quickeſt was adjudged to be the victim.

OCTOSTYLE, in the ancient architecture, is the face of an edifice adorned with eight columns.

OCULUS, the EYE, in anatomy. See there, N° 142.

Oculus Beli, in natural hiſtory, one of the ſemipellucid gems, of a grayiſh white colour, variegated with yellow and with a black central nucleus: it is of a roundiſh form, and its variegations very beautifully repreſent the pupil and iris of the eye; whence the name.

Oculus Mundi, or *Lapis Mutabilis*. See HYDROPHANES.

Oculus Cati. See ASTERIA.

OCYMOPHYLLON, in botany: a name given by Buxbaum to a new genus of plants, the characters of which are theſe: The flower is of the ſtamineous kind, having no petals; this ſtands upon the embryo fruit, which afterwards becomes an oblong quadrangular ſeed-veſſel, divided into four cells, and containing roundiſh and very ſmall ſeeds; its leaves are like thoſe of the common ocymum or baſil, whence its name; and its place of growth is in damp marſhes. Boccone has deſcribed it under the improper name of *glaux*, calling it the *great, green-flowered, marſh glaux*.

OCYMUM, BASIL; a genus of the gymnoſpermia order, belonging to the didynamia claſs of plants; and in the natural method ranking under the 43d order, *Verticillatæ*. The upper lip of the calyx is orbiculated, the inferior one quadrifid; the corolla is reſupinated, with one lip quadrifid, the other undivided; the exterior filament ſends out a reflected proceſs at the baſe. There are eight ſpecies, all of them natives of warm climates, riſing from ſix inches to two feet in height, and having a ſtrong aromatic ſmell, reſembling that of cloves. One of the ſpecies is uſed in the kitchen, particularly by the French cooks, who make great uſe of it in their ſoups and ſauces. This riſes about ten inches high, ſending out branches by pairs oppoſite, from the bottom; the ſtalks and branches are four-cornered; the leaves are oval, ſpear-ſhaped, ending in acute points, and are indented on their edges; the whole plant is hairy, and has a ſtrong ſcent of cloves too powerful for moſt perſons, but to ſome it is very agreeable. Theſe plants are propagated by ſeeds, and will thrive in this country in the open air, and will even ripen their ſeeds if placed in a ſtove or airy glaſs-caſe.

OCZAKOW, or OCZAKOFF, a town of Turkey in Europe, and capital of a ſangiack of the ſame name, inhabited by Tartars. During a late war, here was a Turkiſh garriſon of 20,000 men. However, it was taken by the Ruſſians in 1737, and all thoſe that reſiſted were put to the ſword. The Ruſſians themſelves loſt

18,000 men in the aſſault. The Turks returned the ſame year with 70,000 men to retake it; but were obliged to retire, after the loſs of 20,000. In 1738, the Ruſſians withdrew their garriſon, and demoliſhed the fortifications. It is ſeated on the river Bog, to the weſt of the Nieper, or rather where they both unite and fall into the Black ſea. It is 42 miles ſouth-weſt of Bialagrod, and 190 north by eaſt of Conſtantinople. It has been lately a ſubject of great conteſt between the Ruſſians and Turks. The affair is freſh in our readers memories; but the following more particular account of the place, will not, we truſt, be unacceptable to our readers.—It is called by the Turks *Dzain Crimenda*, is ſeated at the influx of the Nieper into the Black ſea, 120 miles from Bender, to the ſouth-eaſt. The river is here above a mile broad. Hither the Turkiſh galleys retire which guard the mouth of the river, to prevent the Coſſacks from pirating upon the Black ſea. Here is no port, but good anchorage. It is defended by a caſtle, ſurrounded with walls 25 feet high; thoſe of the town are much lower. There are about 2000 people at Oczakow. Below the caſtle are two towns or ſuburbs, ſituated on the declivity of a hill, which on the other ſide has nothing but precipices. To the ſouth of theſe towns is another ſmall caſtle, where is ſome artil[illegible] to prevent veſſels from coming up the river. Here is alſo a tower, in which are always ſome Turks upon the watch to diſcover from afar any of the Coſſacks at ſea, and give notice of them to the galleys by a ſignal. The city is inhabited by Tartars, though garriſoned by Turks. E. Long. 30. 50. N. Lat. 46. 50.

ODA, in the Turkiſh ſeraglio, ſignifies a claſs, order, or chamber. The grand ſignior's pages are divided into five claſſes or chambers. The firſt, which is the loweſt in dignity, is called the *great oda*, from the greater number of perſons that compoſe it; theſe are the juniors, who are taught to read, write, and ſpeak the languages. The ſecond is called the *little oda*, where from the age of 14 or 15 years, till about 20, they are trained up to arms, and the ſtudy of all the polite learning the Turks are acquainted with. The third chamber, called *kilar oda*, conſiſts of 200 pages, who, beſides their other exerciſes, are under the command of the kilardgi-bachi, and ſerve in the pantry and fruitery. The fourth conſiſts only of 24, who are under the command of the khazineda-bachi, and have charge of the treaſure in the grand ſignior's appartment, which they never enter with clothes that have pockets. The fifth is called *kas oda* or *privy-chamber*; and is compoſed of only 40 pages who attend in the prince's chamber. Every night eight of theſe pages keep guard in the grand ſignior's bedchamber while he ſleeps: they take care that the light, which is conſtantly kept in the room, does not glare in his eyes, leſt it ſhould awake him: and if they find him diſturbed with troubleſome dreams, they cauſe him to be awaked by one of their agas.

Oda Bachi, or *Oddabaſſi*, an officer in the Turkiſh ſoldiery, equivalent to a ſerjeant or corporal among us. The common ſoldiers and janizaries, called *oldachis*, after having ſerved a certain term of years, are always preferred and made biquelairs; and of biquelairs in time become odobachis, i. e. corporals of companies, or chiefs of certain diviſions, whoſe number is not fixed; being ſometimes ten, and ſometimes twenty.

Their pay is ſix doubles per month; and they are diſtinguiſhed by a large felt, a foot broad and above a foot long, hanging on the back, with two long oſtrich feathers.

ODE, in poetry, a ſong, or compoſition proper to be ſung. See POETRY.

ODED, a prophet of the Lord, who being at Samaria, when the Iſraelites of the ten tribes returned from the war, with their King Pekah, together with 200,000 of the people of Judah captives, he went out to meet them, and ſaid, "You have ſeen that the Lord God of your fathers was in wrath againſt Judah; he has therefore delivered them into your hands, and you have ſlain them inhumanly, ſo that your cruelty has aſcended up into heaven; and more than this, you would make ſlaves of the children of Judah, who are your brethren, and would add this ſin to the many others you have committed: therefore, hear the counſel that I give you; ſend back theſe captives, leſt the Lord ſhould pour out his fury upon you." Oded having done ſpeaking, ſome of the chiefs of Samaria ſeconded him, and by their remonſtrances prevailed with the Iſraelites to ſet the captives at liberty (2 Chron. xxviii.) See AHAZ.

The enlargement of the captives being obtained, the principal men of Samaria took care of them, gave them clothes and food and other neceſſary aſſiſtance. After which they furniſhed them with horſes, becauſe the greateſt part of them were ſo tired and exhauſted that they were not able to walk. Thus they conducted them to Jericho, which was in the confines of the land of Judah. This is all that is come to our knowledge concerning the prophet Oded.

ODENSEE, the capital of the iſle of Funen, a place of ſuch high antiquity, that ſome Daniſh writers derive its foundation and name from Odin the god and hero of the Gothic nations. "Its name certainly occurs (ſays Mr Coxe) in the earlieſt ages of the Daniſh hiſtory; and it was town of great note long before Copenhagen exiſted. Odenſee ſtands upon a ſmall river, not navigable, and about two miles from the bay of Stegeſtrand. Many of the houſes are ancient, bearing dates about the middle of the 16th century; but part is newly built: it contains about 5200 inhabitants, who carry on ſome commerce, exporting chiefly grain and leather; the latter is much eſteemed, and its goodneſs is ſuppoſed to ariſe from a certain property in the river water, in which it is ſoaked for tanning. The Daniſh cavalry are ſupplied from thence with the greateſt part of their leathern accoutrements.

"Odenſee is the ſeat of a biſhop, which was founded by Harold Blaatand in 980, and is the richeſt in Denmark next to Copenhagen. It has a ſchool, endowed by the celebrated Margaret of Valdemar, in which a certain number of ſcholars, from ſix to 16 years of age, are inſtructed gratis: they live and board in the town, and each receives a yearly penſion; other ſcholarſhips have been alſo founded by private perſons. The whole number amounted to 70. There is alſo a gymnaſium, inſtituted by Chriſtian IV. for the admiſſion of ſtudents at the age of 16. The ſeminary was ſtill further improved by the liberality of Holberg the Daniſh hiſtorian, who protected letters with the ſame zeal with which he cultivated them. It is now greatly fallen from its former flouriſhing ſtate, containing, when I paſſed through the town, only eight ſtudents. The cathedral is a large old brick building, which has nothing remarkable except ſome coſtly monuments of a private Daniſh family. The church, which formerly belonged to the convent of Recolets, contains the ſepulchre of John king of Denmark, and of his ſon Chriſtian II." E. Long. 10. 27. N. Lat. 55. 28.

ODENATUS, a celebrated prince of Palmyra. He very early inured himſelf to bear fatigues, and by hunting leopards and wild beaſts, accuſtomed himſelf to the labours of a military life. He was a faithful friend to the Romans; and when Aurelian had been taken priſoner by Sapor king of Perſia, Odenatus warmly intereſted himſelf in his cauſe, and ſolicited his releaſe, by writing to the conqueror, and by ſending him preſents. The king of Perſia was offended at this liberty of Odenatus, he tore the letter, and ordered the preſents that were offered to be thrown into a river, and in order to puniſh Odenatus, who had the impudence, as he called it, to pay homage to ſo great a monarch as himſelf, he commanded him to appear before him, on pain of being devoted to inſtant deſtruction with all his family, if he dared to refuſe. Odenatus deſpiſed this haughty ſummons of Sapor, and oppoſed force by force. He obtained ſome conſiderable advantages over the troops of the Perſian king and took his wife priſoner, with a great and rich booty. Theſe ſervices were obſerved with gratitude by the Romans; and Gallienus, the then emperor, named Odenatus as his colleague on the throne, and gave the title of *Auguſtus* to his children, and to his wife the celebrated Zenobia. Odenatus inveſted with new power, reſolved to ſignalize himſelf more conſpicuouſly by conquering the barbarians of the north: but his exulting was of ſhort duration: he periſhed by the dagger of one of his own relations, whom he had ſlightly offended at a domeſtic entertainment.— He died at Emeſſa about the 267th year of the Chriſtian era. Zenobia ſucceeded to his titles and honours.

ODER, a river of Germany, which has its ſource near a town of the ſame name in Sileſia, and on the confines of Moravia. It runs north through that province, and then into the Marche of Brandenburg and Pomerania, where it forms a large lake, afterwards falling into the Baltic ſea by three mouths; between which lie the iſlands Uſedom and Wolin. It paſſes by ſeveral towns; as Ratibor, Oppelen, Breſlau, Glogan and Groſſen, in Sileſia; Francfort, Lebus, and Cuſtrin, in Brandenburg; and Gartz, Stetin, Cammin, Wallin, Uſedom, and Wolgaſt, in Pomerania.

ODEUM, in Grecian antiquity, a muſic theatre built by Pericles; the inſide of which was filled with ſeats and ranges of pillars, and on the outſide the roof deſcended ſhelving downwards from a point in the centre, with many bendings, in imitation of the king of Perſia's pavilion. Here the muſical prizes were contended for; and here alſo, according to Ariſtophanes was a tribunal.

ODIN (ſee Frea), in mythology, called alſo in the dialect of the Anglo-Saxons, *Woden* or *Wodan*, a name given by the ancient Scythians to their ſupreme god, and aſſumed, about 70 years before the Chriſtian era, by Sigge, a Scythian prince, who conquered the northern nations, made great changes in their government, manners, religion, and enjoyed great honours, and had even divine honours paid him. According to the account given of this conqueror by Snorro, the ancient hiſtorian of Norway, and his commentator Torfæus, Odin was a Scythian, who withdrew himſelf, with many others in his train, by flight, from the vengeance of the Romans, under the conduct of Pompey; and having officiated as a prieſt in his own country, he aſſumed the direction of the religious worſhip, as well as the civil government, of the nations which he conquered. Having ſubdued Denmark, Sweden, and Norway, he retired to Sweden, where he died. There is nothing certain in this account; but it is probable, that the god, whoſe prophet or prieſt this Scythian pretended to be, was named *Odin*, and that the ignorance of ſucceeding ages confounded the deity with his prieſt, compoſing out of the attributes of the one, and the hiſtory of the other, the character of the northern conqueror. He deluded the people by his enchantments and ſkill in magic: having cut off the head of one Mimer, who in his lifetime was in great reputation for wiſdom, he cauſed it to be embalmed, and perſuaded the Scandinavians that he had reſtored it to the uſe of ſpeech; and he cauſed it to pronounce whatever oracles he wanted. The Icelandic chronicles repreſent Odin as the moſt eloquent and perſuaſive of men; they aſcribe to him the introduction of the art of poetry among the Scandinavians, and likewiſe the invention of the Runic characters. He had alſo the addreſs to perſuade his followers, that he could run over the world in the twinkling of an eye; that he had the direction of the air and tempeſts; that he could transform himſelf into all ſorts of ſhapes, could raiſe the dead, could foretel things to come, deprive his enemies, by enchantment, of health and vigour, and diſcover all the treaſures concealed in the earth. They add, that by his tender and melodious airs, he could make the plains and mountains open and expand with delight; and that the ghoſts, thus attracted, would leave their infernal caverns, and ſtand motionleſs about him. Nor was he leſs dreadful and furious in battle; changing himſelf into the ſhape of a bear, a wild bull, or a lion, and amidſt ranks of enemies committing the moſt horrible devaſtation, without receiving any wound himſelf.

Henry's Hiſt. of Britain, Vol. II.

Dr Henry gives this account of him: "Odin is believed to have been the name of the one true God among the firſt colonies who came from the eaſt and peopled Germany and Scandinavia, and among their poſterity for ſeveral ages. But at length a mighty conqueror, the leader of a new army of adventurers from the eaſt, over-run the north of Europe, erected a great empire, aſſumed the name of *Odin*, and claimed the honours which had been formerly paid to that deity. From thenceforward this deified mortal, under the name of *Odin* or *Wodin*, became the chief object of the idolatrous worſhip of the Saxons and Danes in this iſland, as well as of many other nations. Having been a mighty and ſucceſsful warrior, he was believed to be the god of war, who gave victory, and revived courage in the conflict. Having civilized, in ſome meaſure, the countries which he conquered, and introduced arts formerly unknown, he was alſo worſhipped as the god of arts and artiſts. In a word, to this Odin his deluded worſhippers impiouſly aſcribed all the attributes which belong only to the true God: to him they built magnificent temples, offered many ſacrifices, and conſecrated the fourth day of the week, which is ſtill called by his name in England and in all the other countries where he was formerly worſhipped. Notwithſtanding all this, the founders of [illegible] kingdoms of the Anglo-Saxon heptarchy pretended to be deſcended from Wodin, and ſome of them at the diſtance only of a few generations."

Odin's Fire. We have this account of it in Gough's Camden. "In Evie pariſh, in the Orkneys, near the ſea, are ſome rocks, which frequently in the night appear on fire; and the church of St Michael there was often ſeen full of lights, called fires ſent by Odin to guard their tombs, but now ceaſed. This may be a meteor, or ſome inflammable matter on the cliffs, as at Charmouth, Dorſet."

ODINUS, a celebrated hero of antiquity, who flouriſhed about 70 years before the Chriſtian era, in the northern parts of ancient Germany, or in the modern kingdom of Denmark. He was at the ſame time a prieſt, a ſoldier, a poet, a monarch, and a victor. He impoſed upon the credulity of his ſuperſtitious countrymen, and made them believe that he could raiſe the dead, and that he was acquainted with futurity. When he had extended his power, and increaſed his fame by conqueſt and by artifice, he determined to die in a different way from other men. He aſſembled his friends, and with the ſharp point of a lance he made in his body nine different wounds in the form of a circle; and when expiring he declared that he was going to Scythia, where he ſhould become an immortal god. He added, that he would prepare bliſs and felicity for thoſe of his countrymen who lived a virtuous life, who fought with bravery, and who died like heroes in the field of battle. Theſe injunctions had the wiſhed-for effect: his countrymen ſuperſtitiouſly believed him, and conſtantly recommended themſelves to his protection when they engaged in battle; and they entreated him to receive the ſouls of ſuch as fell in war.

De Odio et Atia. See *False Imprisonment.*

The writ *de odio et atia* was anciently uſed to be directed to the ſheriff, commanding him to inquire whether a priſoner charged with murder was committed upon juſt cauſe of ſuſpicion, or merely *propter odium et atiam*, for hatred and ill will; and if upon the inquiſition due cauſe of ſuſpicion did not then appear, then there iſſued another writ for the ſheriff to admit him to bail. This writ, according to Bracton, ought not to be denied to any man; it being expreſsly ordered to be made out *gratis*, without any denial, by *magna charta*, c. 26. and ſtatute Weſtm. 2. 13 Edw. I. c. 29. But the ſtatute of Gloceſter, 6 Edw. I. c. 9. reſtrained it in the caſe of killing by miſadventure or ſelf defence, and the ſtatute 28 Edw. III. c. 9. aboliſhed it in all caſes whatſoever: but as the ſtat. 42 Ed. III. c. 1. repealed all ſtatutes then in being, contrary to the great charter, Sir Edward Coke is of opinion that the writ *de odio et atia* was thereby revived. See *Habeas Corpus*.

ODO (St,) ſecond abbot of Cluny in France, was illuſtrious for learning and piety in the 10th century. The ſanctity of his life contributed greatly to enlarge the congregation of Cluny; and he was ſo eſteemed, that popes, biſhops, and ſecular princes, uſually choſe him the arbiter of their diſputes. He died about the year 942, and his works are printed in the Bibliotheque of Cluny.

Odo Cantianus, ſo called as being a native of Kent in England, was a Benedictine monk in the 12th century, in which order his learning and eloquence raiſed him to the dignity of prior and abbot. Archbiſhop Becket was his friend; and his panegyric was made by John of Saliſbury. He compoſed Commentaries on the Pentateuch, and the Second Book of Kings; Moral Reflections on the Pſalms; treatiſes entitled, *De Onere Philiſtim; De Moribus Eccleſiaſticis; De Vitiis et Virtutibus Animæ*, &c.

ODOACER, according to Ennodius, was meanly born, and only a private man in the guards of the emperor Auguſtulus, when (A. D. 476, under the conſulſhip of Baſilicus and Armatus) the barbarians choſe him fo —————— The barbarians thought, as they often defended Italy, they had a right at leaſt to part of it; but upon demanding it they were refuſed, and the conſequence was a revolt. Odoacer is ſaid to have been a man of uncommon parts, capable alike of commanding an army or governing a ſtate. Having left his own country when he was very young, to ſerve in Italy, as he was of a ſtature remarkably tall, he was admitted among the emperor's guards, and continued in that ſtation till the above year; when, putting himſelf at the head of the barbarians in the Roman pay, who, though of different nations, had unanimouſly choſen him for their leader, he marched againſt Oreſtes, and his ſon Auguſtulus, who ſtill refuſed to ſhare any of the lands in Italy. The Romans were inferior both in numbers and valour, and were eaſily conquered: Oreſtes was ordered to be ſlain; but the emperor Auguſtulus was ſpared, and, though ſtripped of his dignity, was treated with humanity, and allowed a liberal ſum for his own ſupport and for that of his relations. Odoacer was proclaimed king of Italy; but aſſumed neither the purple nor any other mark of imperial conſequence. He was afterwards defeated and ſlain by Theodoric the Oſtrogoth. See Ostrogoth.

ODONTALGIA, the toothach. See Medicine, N° 210 and 411.

ODONTOIDE, in anatomy, an appellation given to the proceſs of the ſecond vertebra of the neck, from its reſemblance to a tooth.

ODOROUS, or Odoriferous, appellations given to whatever ſmells ſtrongly, whether they be fetid or agreeable; but chiefly to things whoſe ſmell is briſk and pleaſant.

ODYSSEY, the name of an epic poem compoſed by Homer, which, when compared with the Iliad, exhibits its author as the ſetting ſun, whoſe grandeur remains without the heat of his meridian beams.

The poet's deſign in the Odyſſey was to paint the miſeries of a kingdom in the abſence of its ſupreme governor, and the evil conſequences reſulting from a diſregard of law, and of that ſubordination without which ſociety cannot exiſt. With this view he ſets before his countrymen the adventures of a prince who had been obliged to forſake his native country, and to head an army of his ſubjects in a foreign expedition; and he artfully contrives, without interrupting the narrative, to make the reader acquainted with the ſtate of the country in the abſence of its ſovereign. The chief having glorioully finiſhed the enterpriſe in which he was engaged, was returning with his army; but in ſpite of all his eagerneſs to be at home, he was detained on the way by tempeſts for ſeveral years, and caſt upon ſeveral countries differing from each other in manners and in government. In theſe dangers his companions, not ſtrictly obeying his orders, periſh through their own fault. In the mean time the grandees of his country abuſe the freedom which his abſence gave them; conſume his eſtate; conſpire to deſtroy his ſon; endeavour to compel his queen to accept one of them for her huſband; and indulge themſelves in every ſpecies of violence, from a perſuaſion that he would never return. In this they were diſappointed. He returns; and diſcovering himſelf only to his ſon and ſome others who had maintained their allegiance, he is an eye witneſs of the inſolence of his enemies, puniſhes them according to their deſerts, and reſtores to his iſland that tranquillity and repoſe to which it had been a ſtranger during the many years of his abſence.

Such is the fable of the Odyſſey, in which there is no opportunity of diſplaying that vigour and ſublimity which characterize the Iliad. "It deſcends from the dignity of gods and heroes †, and warlike achievements; but in recompenſe we have more pleaſing pictures of ancient manners. Inſtead of that ferocity which reigns in the other poem, this preſents us with the moſt amiable images of hoſpitality and humanity; entertains us with many a wonderful adventure; and inſtructs us by ſuch a conſtant vein of morality and virtue which runs through the poem," ſometimes in precepts, and always in the conduct of the hero, that we ſhould not wonder if Greece, which gave the appellation of *wiſe* to men who uttered ſingle ſentences of truth, had given to Homer the title of *the father of virtue*, for introducing into his work ſuch a number of moral maxims. As a poem, however, the Odyſſey has its faults. The laſt twelve books are tedious and languid; and we are diſappointed by the calm behaviour of Penelope upon the diſcovery of her long loſt huſband.

OECONOMICS, the art of managing the affairs of a family or community; and hence the perſon who takes care of the revenues and other affairs of churches, monaſteries, and the like, is termed *œconomus*.

OECONOMY, denotes the prudent conduct, or diſcreet and frugal management, whether of a man's own eſtate or that of another.

Animal Oeconomy, comprehends the various operations of nature in the generation, nutrition and preſervation of animals †. The doctrine of the animal economy is nearly connected with phyſiology, which explains the ſeveral parts of the human body, their ſtructure, uſe, &c. See Anatomy and Medicine.

OECUMENICAL, ſignifies the ſame with *general* or *univerſal*; as, œcumenical council, biſhop, &c.

OEDEMA, or Phlegmatic Tumour, in medicine and ſurgery, a ſort of tumour attended with pale- ld, yielding little reſiſtance, retaining the print of the finger when preſſed with it, and accompanied with little or no pain.

This tumour obtains no certain ſituation in any particular part of the body, ſince the head, eyelids, hands, and ſometimes part, ſometimes the whole body, is afflicted with it. When the laſt mentioned is the caſe, the patient is ſaid to be troubled with a cachexy, leucophlegmatia, or dropſy. But if any particular part is more ſubject to this diſorder than another, it is certainly the feet, which are at that time called *ſwelled* or *œdematous feet*.

OEDERA, in botany: A genus of the polygamia ſegregata order, belonging to the ſyngeneſia claſs of plants. The calyces are multiflorous; the corollets tubular, hermaphrodite, and one or two feminine ones ligulate; the receptacle is chaffy; the pappus with numerous chaff.

OEDIPUS, the unfortunate king of Thebes, whoſe hiſtory is partly fabulous, flouriſhed about 1266 B. C. It is ſaid he was given by his father to a ſhepherd, who was ordered to put him to death, in order to prevent the misfortunes with which he was threatened by an oracle. But the ſhepherd, being unwilling to kill him with his own hands, tied him by the feet to a tree, that he might be devoured by wild beaſts. The infant was however found in this ſituation by another ſhepherd named *Phorbas*, who carried him to Polybus king of Corinth; where the queen, having no children, educated him with as much care as if he had been her own ſon. When he was grown up, he was informed that he was not the ſon of Polybus: on which, by order of the oracle, he went to ſeek for his father in Phocis; but ſcarce was he arrived in that country, when he met his father on the road, and killed him without knowing him. A ſhort time after, having delivered the country from the monſter called the *Sphinx*, he married Jocaſta, without knowing that ſhe was his mother, and had four children by her; but afterwards, being informed of his inceſt, he quitted the throne, and, thinking himſelf unworthy of the light, put out his eyes. Eteocles and Polynices, who were celebrated amongſt the Greeks, were born of this inceſtuous marriage.

OEGWA, a town on the Gold coaſt of Africa, ſtanding, according to Artus, on the brow of an eminence, raiſing itſelf by a gentle aſcent to a conſiderable height, and defended by rocks, againſt which the waves beat with the utmoſt violence, the noiſe of which is heard at a great diſtance.

Barbot affirms, that Oegwa contains above 500 houſes disjoined by narrow crooked ſtreets; and that from the ſea it has the appearance of an amphitheatre. Des Marchias reduces the number of houſes to 200, in the centre of which ſtands a large ſquare building, the repoſitory of their gold duſt and other commodities. The houſes are built of earth and clay, but convenient, and well furniſhed with chairs, ſtools, mats, carpets, earthen pots, and even looking glaſſes, which laſt they purchaſe from the Europeans. No part of the coaſt is better provided with all kinds of eatables, which are ſent in from the adjacent cantons, and ſold in public markets. Every thing is bought and ſold with gold duſt, which is the ſtandard of all other commodities, and brought hither in great abun-

---

† See *Generation*, *Nutrition*, &c.

dance from all quarters of Fetu, Abrambo, Aſſiento, and Mandingo. The gold is ſold by weight, and the quantity determined by nice ſcales, made in the country before it was frequented by the Europeans: a proof that thoſe negroes are not wholly ignorant of the more refined principles of mechanics. Next to gold, the chief commerce of the place conſiſts in the ſale of fiſh, of which they catch prodigious quantities on the coaſt. Although the natives are brave and warlike, yet in time of peace no people are more induſtrious, their whole time being employed in catching fiſh or cultivating the fruits of the earth. They are extremely expert in throwing the line, and fiſhing by the hook; nor is their intrepidity in combating the elements, and purſuing their employments in all kinds of weather, leſs aſtoniſhing. Every day in the week, except Wedneſday, which is ſacred to the Fetiche, they employ in their ſeveral occupations, and no ſeaſon of the year is exempted from fiſhing. Their canoes weather ſtorms which would endanger the largeſt ſhipping; and the negroes have the dexterity of making their advantage of thoſe ſeaſons, which oblige others to diſcontinue their labours, by throwing their lines with the ſame ſucceſs in tempeſtuous as in calm weather.

OELAND, an iſland of Sweden, ſeated on the Baltic ſea, between the continent of Gothland and the iſle of Gothland. It lies between 56° and 57° of north latitude, and between 17° and 18° of eaſt longitude. It is about 60 miles in length, and 15 in breadth; having a wholeſome air, and a fertile ſoil, with riſing hills, and ſeveral caſtles. It has no town of any great note.

OENANTHE, WATER DROPWORT: A genus of the digynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 45th order, *Umbellatæ*. The florets are difform; thoſe of the diſc ſeſſile and barren; the fruit crowned with the calyx. There are five ſpecies; of which the moſt remarkable is the crocata, or hemlock dropwort, growing frequently on the banks of ditches, rivers, and lakes, in many parts of Britain. The root and leaves of this plant are a ſtrong poiſon; ſeveral perſons have periſhed by eating it through miſtake, either for water parſnips or for celery, which laſt it reſembles pretty much in its leaves. So exceedingly deleterious is this plant, that Mr Lightfoot tells us he has heard the late Mr Chriſtopher d'Ehret, the celebrated botanic painter, ſay, that while he was drawing it, the ſmell or effluvia only rendered him ſo giddy, that he was ſeveral times obliged to quit the room, and walk out in the freſh air to recover himſelf; but recollecting at laſt what might be the probable cauſe of his repeated illneſs, he opened the door and windows of the room, and the free air then enabled him to finiſh his work without any more returns of the giddineſs. Mr Lightfoot informs us, that he has given a ſpoonful of the juice of this plant to a dog, but without any other effect than that of making him very ſick and ſtupid. In about an hour he recovered; and our author has ſeen a goat eat it with impunity. To ſuch of the human ſpecies as have unfortunately ate any part of this plant, a vomit is the moſt approved remedy.

Lobel calls this vegetable *œnanthe aquatica cicutæ facie*. It grows in great plenty all over Pembrokeſhire, and is called by the inhabitants *five-fingered root*: it is much uſed by them in cataplaſms for the felon or worſt kind of whitlow. They eat ſome parts of it, but carefully avoid the roots or ſtalk. Theſe indeed are of a moſt pernicious nature, and never fail to prove inſtantly fatal, unleſs a proper remedy is applied. The following inſtance, in addition to what has been ſaid, of the effects of this plant on man, is given in the Gentleman's Magazine for July 1747.

Three French priſoners being in the fields near the town of Pembroke, dug up a large quantity of a plant with its roots (which they took to be wild celery) to eat with their bread and butter for dinner. After waſhing it, while yet in the fields, they all three ate, or rather only taſted, of the roots.

As they were entering the town, one of them was ſeized with convulſions. The other two ran and ſent a ſurgeon, who endeavoured firſt to bleed, and then vomit him; but in vain, and he died preſently.

Ignorant of the cauſe of their comrade's death, and of their own danger, they gave of theſe roots to eight other priſoners, who all ate ſome of them with their dinner.

A few minutes after, the two who gathered the plants were ſeized in the ſame manner as the firſt; of which one died: The other was bled, and an emetic with great difficulty forced down, on account of his jaws being ſet. This operating, he recovered; but was ſome time much affected with a dizzineſs in his head, though not ſick, or in the leaſt diſordered in his ſtomach. The other eight, being bled and vomited immediately, were ſoon well.

This vegetable is ſo extremely like celery, and therefore, as in the above caſe, ſo apt to be miſtaken for it, that it cannot be enough guarded againſt by all who have a proper regard for themſelves. In the plate (ſee Plate CCCXLVII.), X is the ſhape of the root. *a*, The part cut off from the ſtalk. *b*, A branch taken from the bottom of the ſtalk, where the leaves are largeſt. *c*, A top branch with the umbels of flowers. *d*, An anterior view of the flower in its natural ſize. *e*, A poſterior view of the ſame. *f*, The anterior appearance of the flower through a microſcope. *g*, The poſterior view of the ſame. *h*, A view of the rudiments of the fruit after the decay of the flower. *i*, The ſame magnified. A *, The ſhape of a leaf of *celery*. B, a leaf of parſley.—Theſe two are printed, to prevent any unhappy miſtake in eating the poiſonous plant inſtead of either. We have added to the figures of this dangerous plant theſe leaves of celery and parſley, which, as we have ſaid, it greatly reſembles, in order to ſhow our readers how careful they ought to be in caſe of an accident becauſe of this ſimilarity.

OENKJE, in botany, a ſpecies of iris. See IRIS.

OENOPTÆ, in Grecian antiquity, a kind of cenſors at Athens, who regulated entertainments, and took care that none drank too much, nor too little.

OENOS, in ornithology, the name uſed by authors for the ſtock-dove, or wood-pigeon, called alſo by ſome *vinago*, ſomewhat larger than the common pigeon, but of the ſame ſhape and general colour. Its neck is of a fine changeable hue, as differently oppoſed to the light; and its breaſt, ſhoulders, and wings, are of

Oenothera. a fine purpliſh hue, or red wine colour, from whence it has its name *vinago*. Its legs are red, and feathered a little below the joint.

OENOTHERA, TREE-PRIMROSE: A genus of the monogynia order, belonging to the octandria claſs of plants: and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quadrifid; the petals four; the capſule cylindric beneath; the ſeeds naked. There are ſeven ſpecies; the moſt remarkable of which are,

1. The biennis, or common biennial tree-primroſe. It hath a long, thick, deeply ſtriking root; crowned with many large, oval, ſpear-ſhaped, plane, ſpreading leaves; upright, thick, firm, rough, hairy ſtems, riſing three or four feet high; garniſhed with long, narrow, lanceolate, cloſe ſitting leaves, irregularly; and at all the axillas, from the middle upwards, large bright yellow flowers.

2. Octovalvis, or octovalved, ſmooth, biennial tree-primroſe, hath upright, firm, ſomewhat hairy ſtems, riſing a yard high; oblong, ſpear-ſhaped, pointed, plane, ſmooth leaves; and at the axillas large bright yellow flowers.

3. The fruticoſa, or ſhrubby, narrow-leaved perennial tree-primroſe, hath long thick roots; upright under ſhrubby-like red ſtems, two or three feet high; ſpear ſhaped, lightly indented leaves: and at the axillas pedunculated cluſters of yellow flowers, ſucceeded by pedicelloted, acute angled capſules.

4. The pumila, or low perennial tree-primroſe, hath fibrous roots, crowned with many oval, ſpear-ſhaped, cloſe ſitting leaves: ſlender herbaceous ſtems from 10 to 12 inches long; garniſhed with ſpear-ſhaped, blunt, ſmooth leaves, having very ſhort footſtalks; and at the axillas ſmalliſh bright yellow flowers, ſucceeded by acute-angled capſules.

All theſe plants flower very profuſely in June and July, coming out almoſt half the length of the ſtalks from the axillas; and as the ſtalk advances in ſtature new flowers are produced, ſucceeding thoſe below; in which order the plants continue flowering from about midſummer till October: each flower is moderately large and conſpicuous, conſiſting of four plane petals, which with the calyx forms a very long tube below, and ſpreading above, generally expand moſt towards the evening; and are ſucceeded by plenty of ſeed in autumn for propagation.

Theſe plants are exotics from America; but are all very hardy, proſper in any common ſoil and ſituation, and have been long in the Engliſh gardens, eſpecially the three firſt ſorts; but the œnothera biennis is the moſt commonly known.

The firſt and ſecond ſpecies are biennial, and the third and fourth are perennial in root.

They are proper to be employed as plants of ornament for embelliſhing the pleaſure garden; they may be placed anywhere, and will effect a very agreeable variety three or four months with their plentiful blow of flowers.

The biennial kinds muſt be raiſed annually from ſeed, for they totally periſh after they have flowered. But the perennials, once raiſed, continue for years by the root.

The propagation of all the ſorts is by ſeed, and the perennial alſo by parting the roots.

Oenotria OENOTRIA, an ancient name of Italy; ſo called from the *Oenotri*, (Virgil); inhabiting between Pæſtum and Tarentum, (Ovid). Originally Arcadians, (Dionyſius Halicarnaſſæus), who came under the conduct of Oenotrus ſon of Lycaon, 17 generations before the war of Troy, or 459 years, at 27 years each generation, and gave name to the people. Cato derives the name from *Oenotrus*, king of the Sabines and Etruſcans; but Varro from *Oenotrus*, king of the Latins; and Servius from the Greek name for wine, for which Italy was famous; of which opinion is Strabo.

Oeſtrus. OENOTRIDES (Strabo, Pliny), two ſmall iſlands in the Tuſcan ſea, over againſt Velia, a town of Lucania, called *Pontia* and *Iſcia*; now *Penza* and *Iſchia*, on the coaſt of the Principato Citra, or to the weſt of Naples. So called from the *Oenotri*, an ancient people of Italy.

OESEL, an iſland of the Baltic ſea, at the entrance of the gulf of Livonia. It is about 70 miles in length, and 50 in breadth, and contains 10 pariſhes. It is defended by the fortreſſes of Airenſburg and Sonneburg. It lies between 22° and 24° of eaſt longitude, and between 58° and 59° of north latitude.

OESOPHAGUS, in anatomy, the GULA, or *Gullet*, is a membranaceous canal, reaching from the fauces to the ſtomach, and conveying into it the food taken in at the mouth. See ANATOMY, N° 92.

Plate CCCL. OESTRUS, in zoology, a genus of inſects belonging to the order of diptera. It has no mouth; but three punctures, without trunk or beak: Antennæ taper, proceeding from a lenticular joint. There are five ſpecies.

1. *Bovis, the breeze* or *gad fly.*—Thorax yellow, with a black tranſverſe line between the wings: Abdomen tawny, with fine black tranſverſe lines; laſt ſegment black: Wings white, with a brown tranſverſe line, and three brown ſpots. Size of the large blue fly. Depoſites its eggs under the ſkin on the backs of oxen, where the maggots are nouriſhed the whole winter till the month of June; and plague the cattle ſo all the ſummer, that they are obliged to fly for refuge into the water, and dare not quit it the whole day.

2. *The hæmorrhoidalis.*—Body long, black, covered with tawny hair; middle of the thorax leſs hairy: wings immaculate; antennæ very ſhort: Length half an inch. Depoſites its eggs in the rectum of horſes, and occaſions great torments. See BOTTS.

3. *Ovis, the gray fly.*—Spotted with black; front pale yellow; legs browniſh; wings with ſhort black veins: length half an inch. Breeds in the frontal ſinus of ſheep; where the maggots hatched from the eggs, lodge the whole winter, vellicating the internal membranes, and often bringing on death.

5. *The naſalis.*—Body black: but the head, thorax, and abdomen, covered with pale red hair, except the firſt ſegment of the latter, which is covered with white hair; the wings immaculate. Breeds in the fauces of horſes, entering by their noſe.

5. *The tarandi.*—Thorax yellow; with a black line between the wings, which are immaculate: Abdomen tawny, laſt ſegment black. Infeſt the back of the rein deer, ſo as greatly to retard the breed. The rein deer of Lapland are obliged every year to fly to the Alpine mountains, to eſcape the purſuit of theſe

Ocelaxochitl.

inſects: yet a fourth part of their number periſh by them at two years old; the reſt are emaciated, and have their ſkins ſpoiled. It is one of the moſt curious genera of inſects. They are diſtinguiſhed into ſeveral ſpecies, by reaſon of the different places wherein they depoſite their eggs. Some, inſtructed by nature that their eggs cannot be hatched but under the ſkins of living creatures, ſuch as bulls, cows, rein deer, ſtags, and camels, fix upon them at the inſtant of laying their eggs. From the hinder part of their body iſſues a whimble of wonderful ſtructure. It is a ſcaly cylinder, compoſed of four tubes, which draw out like the pieces of a ſpying glaſs; the laſt is armed with three hooks and is the gimblet with which the œſtri bore through the tough hides of horned cattle. The animal ſeems to experience no pain from the puncture, unleſs the inſect, plunging too deep, touches ſome nervous fibre; in which caſe, the beaſt runs about, and becomes furious. The eggs being hatched, the grub feeds on the matter of the wound. The place of its abode forms upon the body of the quadrupeds a bunch ſometimes above an inch high. When full grown, the larva breaks through the tumor, and ſlides down to the ground; for doing which it takes the cool of the morning, that it may neither be overpowered by the heat of the day, nor chilled by the cold of the night: it then digs itſelf a burrow, into which it retires. Its ſkin grows hard, and turns to a very ſolid ſhell. There it is transformed to a chryſalis, and afterwards to a winged inſect. Nature has provided for every exigence: the ſhell wherein the œſtrus is encloſed, is of ſo ſtrong a texture that it could not make its way out, if at one of the ends there were not a ſmall valve, faſtened only by a very ſlight filament. The firſt puſh the œſtrus makes, the door gives way and the priſon opens. The inſect wings its way to woods and places frequented by cattle.

OETA (anc. geog.), a mountain of Theſſaly, extending from Thermopylæ weſtward to the Sinus Ambracius, and in ſome meaſure cutting at right angles the mountainous country ſtretching out between Parnaſſus to the ſouth, and Pindus to the north. At Thermopylæ it is very rough and high, riſing and ending in ſharp and ſteep rocks, affording a narrow paſſage between it and the ſea from Theſſaly to Locris (Strabo), with two paths over it; the one above [illegible], very ſteep and high; the other through the country of the Ænianes, much eaſier and readier for travellers; by this it was that Leonidas was attacked in rear by the Perſians (Pauſanias). Here Hercules laid himſelf on the funeral pile (Silius Italicus, Ovid); the [illegible] thence called *Pyra* (Livy), who ſays, that the extreme mountains to the eaſt are called *Oeta*; and hence the poets allege, that day, night, ſun, and ſtars, aroſe from Oeta (Seneca, Statius, Silius Italicus, Catullus, Virgil's *Culex*)—circumſtances which ſhow the height of this mountain.

OETING, a town of Germany, in Upper Bavaria, under the juriſdiction of Buckhauſen. It is divided into the upper and the lower town, and ſeated on the river Inn, eight miles weſt of Buckhauſen. E. Long. 12. 47. N. Lat. 48. 0. There is a great reſort of pilgrims to the old chapel.

Oeting, or *Oetingen*, a town of Germany, in the circle of Suabia, and capital of a county of the ſame name, ſeated on the river Wirnitz. E. Long. 10. 45. N. Lat. 48. 52.

Oeting, a county of Germany, in the circle of Suabia, bounded on the north and eaſt by Franconia; on the ſouth by the duchy of Neuburg; and on the weſt by that of Wirtemberg. It is about 40 miles from eaſt to weſt, and 20 from north to ſouth.

OFFA's-dyke, an intrenchment caſt up by Offa, a Saxon king, to defend England againſt the incurſions of the Welſh. It runs through Hertfordſhire, Shropſhire, Montgomeryſhire, Denbighſhire, and Flintſhire.

OFFANTO, a river of Italy, in the kingdom of Naples. It riſes in the Apennine mountains, in the Farther Principato; and paſſing by Conza, and Monte Verde, it afterwards ſeparates the Capitanata from the Baſilicata and the Terra-di-Bari, and then it falls into the gulf of Venice, near Salpe.

OFFENCE, in law, an act committed againſt the law, or omitted where the law requires it.

OFFERINGS. The Hebrews had ſeveral kinds of offerings, which they preſented at the temple. Some were free-will offerings, and others were of obligation. The firſt fruits, the tenths, the ſin offerings, were of obligation; the peace offerings, vows, offerings of wine, oil, bread, ſalt, and other things, which were made to the temple or to the miniſters of the Lord, were offerings of devotion. The Hebrews called all offerings in general *corban*. But the offerings of bread, ſalt, fruits, and liquors, as wine and oil, which were preſented to the temple, they called *mincha*. The ſacrifices are not properly offerings, and are not commonly included under that name. See Corban and Sacrifice.

The offerings of grain, meal, bread, cakes, fruits, wine, ſalt, and oil, were common in the temple. Sometimes theſe offerings were alone, and ſometimes they accompanied the ſacrifices. Honey was never offered with the ſacrifices; but it might be offered alone in the quality of firſt fruits. Now theſe were the rules that were obſerved in the preſenting of thoſe offerings, called in Hebrew *mincha*, or *korbon mincha*; in the Septuagint, *offerings of ſacrifice*; and the ſame by St Jerome, *oblationem ſacrificii*; but by our tranſlators, *meat offerings* (Lev. ii. 1, &c.) There were five ſorts of theſe offerings: 1. Fine flour or meal. 2. Cakes of ſeveral ſorts, baked in an oven. 3. Cakes baked upon a plate. 4. Another ſort of cakes, baked upon a gridiron, or plate with holes in it. 5. The firſt fruits of the new corn, which were offered either pure and without mixture, or roaſted or parched in the ear, or out of the ear.

The cakes were kneaded with oil olive, or fried with oil in a pan, or only dipped in oil after they were baked. The bread offered to be preſented upon the altar, was to be without leaven; for leaven was never offered upon the altar, nor with the ſacrifices. But they might make preſents of common bread to the prieſts and miniſters of the temple. See Cake, &c.

The offerings now mentioned were appointed on account of the poorer ſort, who could not go to the charge of ſacrificing animals. And even thoſe that offered living victims were not excuſed from giving meal, wine, and ſalt, which was to go along with the greater ſacrifices. And alſo thoſe that offered only oblations of bread or of meal, offered alſo oil, incenſe, ſalt, and wine, which were in a manner the ſeaſoning of it. The prieſt in waiting received the offerings from the hand of him that offered them; laid a part of them upon the altar, and reſerved the reſt for his own ſubſiſtence: that was his right as a miniſter of the Lord. Nothing was burnt quite up but the incenſe, of which the prieſt kept back nothing for his own ſhare.

When an Iſraelite offered a loaf to the prieſt, or a whole cake, the prieſt broke the loaf or the cake into two parts, ſetting that part aſide that he reſerved to himſelf, and broke the other [illegible] crumbs; poured oil upon it, ſalt, wine; and incenſe, and ſpread the whole upon the fire of the altar. If theſe offerings be accompanied by an animal for a ſacrifice, it was all thrown upon the victim, to be conſumed along with it.

If theſe offerings were the ears of new corn, either of wheat or barley, theſe ears were parched at the fire or in the flame, and rubbed in the hand, and then offered to the prieſt in a veſſel; over which he put oil, incenſe, wine, and ſalt, and then burnt it upon the altar, firſt having taken as much of it as of right belonged to himſelf.

The greateſt part of theſe offerings were voluntary, and of pure devotion. But when an animal was offered in ſacrifice, they were not at liberty to omit theſe offerings. Every thing was to be ſupplied that was to accompany the ſacrifice, and which ſerved as a ſeaſoning to the victim. There are ſome caſes in which the law requires only offerings of corn, or bread: for example, when they offered the firſt fruits of their harveſt, whether they were offered ſolemnly by the whole nation, or by the devotion of private perſons.

As to the quantity of meal, oil, wine, or ſalt, which was to go along with the ſacrifices, we cannot eaſily ſee that the law had determined it. Generally the prieſt threw an handful of meal or crumbs upon the fire of the altar, with wine, oil, and ſalt in proportion, and all the incenſe. All the reſt belonged to him, the quantity depended upon the liberality of the offerer. We obſerve in more places than one, that Moſes appoints an aſſaron, or the tenth part of an ephah of meal, for thoſe that had not wherewithal to offer the appointed ſin offerings (Lev. v. 11. xiv. 21.) In the ſolemn offerings of the firſt fruits for the whole nation, they offered an entire ſheaf of corn, a lamb of a year old, two tenths or two aſſarons of fine meal mixed with oil, and a quarter of an hin of wine for the libation. (Lev. xxiii. 10, 11, 12, &c.)

In the ſacrifice of jealouſy (Numb. v. 15.), when a jealous huſband accuſed his wife of infidelity, the huſband offered the tenth part of a ſatum of barley-meal, without oil or incenſe, becauſe, it was a ſacrifice of jealouſy, to diſcover whether his wife was guilty or not.

The offerings of the fruits of the earth, of bread, of wine, oil, and ſalt, are the moſt ancient of any that have come to our knowledge. Cain offered to the Lord of the fruits of the earth, the firſt fruits of his labour (Gen. iv. 3, 4.) Abel offered the firſtlings of his flocks, and of their fat. The heathen have nothing more ancient in their religion, that theſe ſorts of offerings made to their gods. They offered clean wheat, flour, and bread.

OFFICE, a particular charge or truſt, or a dignity attended with a public function, See Honour.—The word is primarily uſed in ſpeaking of the offices of judicature and policy; as the office of ſecretary of ſtate, the office of a ſheriff, of a juſtice of peace, &c.

Office alſo ſignifies a place or apartment appointed for officers to attend in, in order to diſcharge their reſpective duties and employments; as the ſecretary's office, ordnance office, exciſe office, ſignet office, paper office, pipe office, ſix clerks office, &c.

Office, in architecture, denotes all the apartments appointed for the neceſſary occaſions of a palace or great houſe; as kitchen, pantrics, confectionaries, &c.

Office, in the canon law, is uſual for a benefice, that has no juriſdiction annexed to it.

Duty upon Offices *and Penſions*, a branch of the king's extraordinary perpetual revenue, conſiſting in a payment of 1s. in the pound (over and above all other duties) out of all ſalaries, fees, and perquiſites of offices and penſions payable by the crown. This highly popular taxation was impoſed by ſtat. 31 Geo. II. c. 22. and is under the direction of the commiſſioners of the land tax.

OFFICER, a perſon poſſeſſed of a poſt or office. See the preceding article.

The great officers of the crown, or ſtate, are, The lord high ſteward, the lord high chancellor, the lord high treaſurer, the lord preſident of the council, the lord privy ſeal, the lord chamberlain, the lord high conſtable, and the earl marſhal; each of which ſee under its proper article.

Non-commiſſioned Officers, are ſerjeant majors, quarter maſter ſerjeants, ſerjeants, corporals, drum and fife majors; who are nominated by their reſpective captains, and appointed by the commanding officers of regiments, and by them reduced without a court martial.

Orderly non-commiſſioned Officers, are thoſe who are orderly, or on duty for that week; who, on hearing the drum beat for orders, are to repair to the place appointed to receive them, and to take down in writing, in the orderly book, what is dictated by the adjutant, or ſerjeant major: they are then immediately to ſhow theſe orders to the officers of the company, and afterwards warn the men for duty.

Flag Officers. See *Flag Officers*, and Admirals.

Commiſſion Officers, are ſuch as are appointed by the king's commiſſion. Such are all from the general to the cornet and enſign incluſive. They are thus called in contradiſtinction to [illegible] commiſſioned officers. See *Non-commiſſioned* Officers.

General Officers, are thoſe whoſe command is not limited to a ſingle company, troop, or regiment; but extends to a body of forces compoſed of ſeveral regiments: ſuch are the general, lieutenant general, major general, and brigadier.

Officers of the Houſehold. See the article Houſehold.

Staff Officers, are ſuch as, in the king's preſence, bear a white ſtaff or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: ſuch are the lord ſteward, lord chamberlain, lord treaſurer, &c.

The white ſtaff is taken for a commiſſion; and, at the king's death, each of theſe officers breaks his ſtaff over the herſe made for the king's body, and by this means lays down his commiſſion, and diſcharges all his inferior officers.

Subaltern Officers, are all who adminiſter juſtice in the name of ſubjects; as thoſe who act under the earl marſhal, admiral, &c. In the army, the ſubaltern officers are the lieutenants, cornets, enſigns, ſerjeants, and corporals.

OFFICIAL, in the canon law, an eccleſiaſtical judge, appointed by a biſhop, chapter, abbot, &c. with charge of the ſpiritual juriſdiction of the dioceſe.

Official, is alſo a deputy appointed by an archdeacon as his aſſiſtant, who ſits as judge in the archdeacon's court.

OFFICINAL, in pharmacy, an appellation given to ſuch medicines, whether ſimple or compound, as are required to be conſtantly kept in the apothecaries ſhops. The *officinal ſimples* are appointed, among us, by the College of Phyſicians; and the manner of making the compoſitions directed in their diſpenſatory. See Pharmacy.

OFFING, or Offin, in the ſea language, that part of the ſea a good diſtance from ſhore, where there is deep water, and no need of a pilot to conduct the ſhip: thus, if a ſhip from ſhore be ſeen ſailing out to ſeaward, they ſay, *ſhe ſtands for the offing*; and if a ſhip, having the ſhore near her, have another a good way without her, or towards the ſea, they ſay, *that ſhip is in the offing.*

OFF-SETS, in gardening, are the young ſhoots that ſpring from the roots of plants; which being carefully ſeparated, and planted in a proper ſoil, ſerve to propagate the ſpecies.

Off-sets, in ſurveying, are perpendiculars let fall, and meaſuring from the ſtationary lines to the hedge, fence, or extremity of an encloſure.

OGEE, or O. G. in architecture, a moulding conſiſting of two members, the one concave and the other convex; or of a round and hollow, like an S. See Architecture.

OGHAMS, a particular kind of ſteganography, or writing in cypher practiſed by the Iriſh; of which there were three kinds: The firſt was compoſed of certain lines and marks, which derived their power from their ſituation and poſition, as they ſtand in relation to one principal line, over or under which they are placed, or through which they are drawn; the principal line is horizontal, and ſerveth for a rule or guide, whoſe upper part is called the left, and the under ſide the right; above, under, and through which line, the characters or marks are drawn, which ſtand in the place of vowels, conſonants, diphthongs, and triphthongs. Some authors have doubted the exiſtence of this ſpecies of writing in cypher, called *Ogham* among the Iriſh: but theſe doubts are perhaps ill founded; for ſeveral MSS. in this character ſtill exiſt, from which Mr Aſtle has given a plate of them.

OGILBY (John), an eminent writer, was born in or near Edinburgh, about the 17th of November 1600. His father having ſpent his eſtate, and being priſoner in the King's Bench for debt, could contribute but little to his education; however, he obtained ſome knowledge in the Latin grammar, and afterwards ſo much money as to procure his father's diſcharge from priſon, and to bind himſelf an apprentice to a dancing-maſter in London; when, by his dexterity in his profeſſion, and his complaiſant behaviour to his maſter's ſcholars, he obtained money to buy out the remainder of his time, and ſet up for himſelf. But being afterwards appointed to dance in the duke of Buckingham's great maſk, he by a falſe ſtep ſtrained a vein in the inſide of his leg, which occaſioned his being ever after ſomewhat lame. When Thomas earl of Strafford was made lord-lieutenant of Ireland, he was entertained as a dancing maſter in his family, and made one of the earl's troop of guards; at which time he compoſed a humorous piece called the *Character of a Trooper.* He was ſoon after appointed maſter of the revels in Ireland, and built a theatre at Dublin. About the time of the concluſion of the war in England, he left Ireland; and, being ſhipwrecked, came to London in a neceſſitous condition; but ſoon after walked to Cambridge, where, being aſſiſted by ſeveral ſcholars, he became ſo complete a maſter of the Latin tongue, that in 1649 he publiſhed a tranſlation of Virgil. He ſoon after learned Greek; and in 1660 publiſhed, in folio, a tranſlation of Homer's Iliad, with Annotations. About two years after he went into Ireland, where he was made maſter of the revels by patent. He then built another theatre in Dublin, which coſt him about 1000l. He publiſhed at London, in folio, a tranſlation of Homer's Odyſſey, with Annotations; and afterwards wrote two heroic poems, entitled the *Epheſian Matron*, and the *Roman Slave.* He next compoſed the Carolics, an epic poem, in 12 books, in honour of King Charles I. but this was entirely loſt in the fire of London; when Mr Ogilby's houſe in White Friars was burnt down, and his whole fortune, except to the value of five pounds, deſtroyed. He, however, ſoon procured his houſe to be rebuilt, ſet up a printing-office within it, was appointed his majeſty's coſmographer and geographic printer, and printed ſeveral great works, tranſlated or collected by himſelf and his aſſiſtants, particularly his Atlas. He died in 1676.

OGIVE, in architecture, an arch or branch of a Gothic vault; which, inſtead of being circular, paſſes diagonally from one angle to another, and forms a croſs with the other arches. The middle, where the ogives croſs each other, is called the *key*; being cut in form of a roſe, or a *cul de lampe.* The members or mouldings of the ogives are called *nerves*, *branches*, or *reins*; and the arches which ſeparate the ogives, *double arches.*

OGYGES, king of the Thebans, or, according to others, of Ogygia and Actæ, afterwards called *Bœotia and Attica.* He is recorded to have been the firſt founder of Thebes and Eleuſis. The famous deluge happened in his time, in which ſome ſay he periſhed with all his ſubjects, 1796 B. C.

OGYGIA (Homer), the iſland of Calypſo; placed by Pliny in the Sinus Scylaceus, in the Ionian ſea, oppoſite to the promontory Lacinium; by Mela in the ſtrait of Sicily, calling it *Ææa*; which others place at the promontory Circeium, and call it the iſland of *Circe.*

Ogygia, the ancient name of Thebes in Bœotia: ſo called from Ogyges, an ancient king, under whom happened

Ohio
Oil.

happened a great deluge, 1020 years before the firſt Olympiad.

OHIO, a river of North America, called by the French the *Beautiful River*, has its ſource between the Allegany mountains and the lake Erie; and running ſouth-weſt through a moſt delightful country, and alſo receiving many ſmaller rivers in its paſſage, at length falls into the Miſſiſſippi, in about 37 degrees of latitude. The French had ſeveral forts on and near it; but the whole country through which it flows was ceded by the peace of 1763 to the Britiſh.

OHETEROA, one of the South ſea iſlands lately diſcovered, is ſituated in W. Long. 150. 47. S. Lat. 22. 27. It is neither fertile nor populous; nor has it any harbour or anchorage fit for ſhipping, and the diſpoſition of the people is hoſtile to ſuch as viſit them.

OIL, in natural hiſtory, an unctuous inflammable ſubſtance, drawn from ſeveral natural bodies, as animal and vegetable ſnbſtances.

Animal oils are their fats, which are originally vegetable oils: all animal ſubſtances yield them, together with their volatile ſalts, in diſtillation.

Vegetable oils are obtained by expreſſion, infuſion, and diſtillation.

The oils by expreſſion are obtained from the ſeed, leaves, fruit, and bark of plants; thus, the ſeed of muſtard, and of the ſun flower, almonds, nuts, beech maſt, &c. afford a copious oil by expreſſion; and the leaves of roſemary, mint, rue, wormwood, thyme, ſage, &c. the berries of juniper, olives, Indian cloves, nutmeg, mace, &c. the barks of cinnamon, ſaſſafras, and clove, yield a conſiderable proportion of eſſential oil by diſtillation.

The method of procuring oils by expreſſion is very ſimple: thus, if either ſweet or bitter almonds, that are freſh, be pounded in a mortar, the oil may be forced out with a preſs, not heated: and in the ſame manner ſhould the oil be preſſed from linſeed and muſtard. The avoiding the uſe of heat, in preparing theſe oils intended for internal medicinal uſe, is of great importance, as heat gives them a very prejudicial rancidneſs.

This method holds of all thoſe vegetable matters that contain a copious oil, in a looſe manner, or in certain cavities or receptacles; the ſides whereof being broken, or ſqueezed, makes them let go the oil they contain: and thus the zeſt or oil of lemon peel, orange peel, citron peel, &c. may be readily obtained by preſſure, without the uſe of fire. But how far this method of obtaining oils may be applied to advantage, ſeems not hitherto conſidered. It has been commonly applied to olives, almonds, linſeed, rape ſeed, beech maſt, ben-nut, walnuts, bay-berries, mace, nutmeg, &c. but not, that we know of, to juniper berries, caſhew nuts, Indian cloves, pine apples, and many other ſubſtances that might be enumerated, both of foreign and domeſtic growth. It has, however, been of late ſucceſsfully applied to muſtard ſeed, ſo as to extract a curious gold-coloured oil, leaving a cake behind, fit for making the common table muſtard.

Certain dry matters, as well as moiſt ones, may be made to afford oils by expreſſion, by grinding them into a meal, which being ſuſpended to receive the vapour of boiling water, will thus be moiſtened ſo as to afford an oil in the ſame manner as almonds; and thus an oil may be procured from linſeed, hemp ſeed, lettuce ſeed, white poppy ſeed, &c.

Oil.

As to the treatment of oils obtained by expreſſion, they ſhould be ſuffered to depurate themſelves by ſtanding in a moderately cool place, to ſeparate from their water, and depoſite their fæces; from both which they ought to be carefully freed. And if they are not thus rendered ſufficiently pure, they may be waſhed well with freſh water, then thoroughly ſeparated from it again by the ſeparating glaſs, whereby they will be rendered bright and clear.

The next claſs of oils are thoſe made by infuſion, or decoction, wherein the virtues of ſome herb or flower are drawn out in the oil; as the oil of roſes, chamomile, hypericum, alder, &c. However, theſe require to be differently treated: thus, for the ſcented flowers, particularly roſes, inſolation does [illegible]; becauſe much boiling would exhale their more fragrant parts: but oils impregnated with green herbs, as thoſe of chamomile and alder, require long boiling, before they receive the green colour deſired. And, in general, no oils will bear to be boiled any longer than there remains ſome aqueous humidity, without turning black.

There are many compound oils prepared in the ſame manner, viz. by boiling and inſolation, and then ſtraining off the oil for uſe.

The ſame contrivance has likewiſe its uſe in making eſſences for the ſervice of the perfumer; not only where eſſential oils cannot be well obtained in ſufficient quantities, but alſo where they are too dear. The eſſential oil of jeſſamine flowers, honeyſuckles, ſweet briar, damaſk roſes, lilies of the valley, &c. are either extremely dear, or ſcarcely obtainable by diſtillation; and, in ſome of them, the odorous matter is ſo ſubtle, as almoſt to be loſt in the operation. But if theſe flowers be barely infuſed in fine oil of nuts, or oil of ben, drawn without heat, and kept in a cool place, their ſubtile odorous matter will thus paſs into the oil, and richly impregnate it with their flavour. And theſe eſſences may be rendered ſtill more perfect by ſtraining off the oil at firſt put on, and letting it ſtand again, without heat, upon freſh flowers; repeating the operation twice or thrice.

Oils or fats may likewiſe be obtained, by boiling and expreſſion, from certain animal ſubſtances; for the membranes which contain the fat, being chopped ſmall, and ſet in a pan over the fire, become fit for the canvas bags, and, by preſſure, afford a large quantity of fat; as we ſee in the art of chandlery, which thus extracting the oily matter, leaves a cake behind, commonly called *graves*.

As to the eſſential oils of vegetables, they are obtained by diſtillation with an alembic and a large refrigeratory. Water muſt be added to the materials in ſufficient quantity, to prevent their burning; and they ſhould be macerated or digeſted in that water, a little time before diſtillation. The oil comes over with the water; and either ſwims on the top, or ſinks to the bottom, according as it is ſpecifically heavier or lighter than water.

This proceſs is applicable to the diſtilling of the eſſential oils from flowers, leaves, barks, roots, woods, gums, and balſams, with a ſlight alteration of circumſtances, as by longer digeſtion, briſker diſtillation, &c. according to the tenacity and hardneſs of the ſubject, the ponderoſity of the oil, &c.

Eſſential oils may be divided into two claſſes, according to their different ſpecific gravities; ſome floating upon water, and others readily ſinking to the bottom. Thus, the eſſential oils of cloves, cinnamon, and ſaſſafras, readily ſink, whereas thoſe of lavender, marjoram, mint, &c. ſwim, in water: the lighteſt of theſe eſſential oils is, perhaps, that of citron peel, which even floats in ſpirit of wine; and the heavieſt ſeems to be oil of ſaſſafras.

For obtaining the full quantity of the more ponderous oils from cinnamon, cloves, ſaſſafras, &c. it is proper to reduce the ſubjects to powder; to digeſt this powder for ſome days in a warm place, with thrice its quantity of ſoft river water, made very ſaline by the addition of ſea ſalt, or ſharp with oil of vitriol; to uſe the ſtrained decoction, or liquor left behind in the ſtill, inſtead of common water, for freſh digeſtion; to uſe for the ſame purpoſe the water of the ſecond running, after being cleared of its oil; not to diſtil too large a quantity of theſe ſubjects at once; to leave a conſiderable part of the ſtill, or about one fourth, empty; to uſe a briſk fire, or a ſtrong boiling heat, at the firſt, but to ſlacken it afterwards; to have a low ſtill head, with a proper internal ledge and current leading to the noſe of the worm; and, finally, to cohabate the water, or pour back the liquor of the ſecond running upon the matter in the ſtill, repeating this once or twice.

The directions here laid down for obtaining the ponderous oils to advantage, are eaſily transferred to the obtaining of the lighter; ſo that we need not dwell particularly upon them.

Many of the eſſential oils being dear, it is a very common practice to adulterate or debaſe them ſeveral ways, ſo as to render them cheaper both to the ſeller and the buyer. Theſe ſeveral ways ſeem reducible to three general kinds, each of which has its proper method of detection, viz. 1. With expreſſed oils. 2. With alcohol. And, 3. With cheaper eſſential oils.

If an eſſential oil be adulterated with an expreſſed oil, it is eaſy to diſcover the fraud; by adding a little ſpirit of wine to a few drops of the ſuſpected eſſential oil, and ſhaking them together; for the ſpirit will diſſolve all the oil that is eſſential, or procured by diſtillation, and leave all the expreſſed oil that was mixed with it, untouched.

If an eſſential oil be adulterated with alcohol, or rectified ſpirit of wine, it may be done in any proportion, up to that of an equal quantity, without being eaſily diſcoverable either by the ſmell or taſte: the way to diſcover this fraud, is to put a few drops of the oil into a glaſs of fair water; and if the oil be adulterated with ſpirit, the water will immediately turn milky, and, by continuing to ſhake the glaſs, the whole quantity of ſpirit will be abſorbed by the water, and leave the oil pure at top.

Finally, If an eſſential oil be adulterated by a cheaper eſſential oil, this is commonly done very artfully: the method is to put fir wood, turpentine, or oil of turpentine, into the ſtill, along with the herbs to be diſtilled for their oil, ſuch as roſemary, lavender, origanum, &c. and by this means the oil of turpentine diſtilled from theſe ingredients comes over in great quantity, and intimately blended with the oil of the genuine ingredient. The oils thus adulterated always diſcover themſelves in time, by their own flavour being overpowered by the turpentine ſmell: but the ready way to detect the fraud, is to drench a piece of rag, or paper, in the oil, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine ſcent behind.

The virtues of oils, being the ſame with thoſe of the ſubſtances from whence they are obtained, may be learned under their ſeveral articles, to which we refer.

We have this account of different oils in the iſland of Madagaſcar in the Univerſal Hiſtory.

Oils are of different ſorts, the moſt common are thoſe of menach-tanhetanhe, menach ſignifying oil, menachil, menach-chouivau, menach-maſoutra, menach-vourave, menach-apocapouc, menach-vintang, and menach-arame. Menach-tanhetanhe is drawn from a particular plant, called, in the language of the country, *tanhetanhe*, and known in Europe by the name of *palma Chriſti*, or *ricinus*. Menachil is an oil from the ſeed of ſeſame, which they call *voancaze*; a great quantity whereof is made in the valley of Amboule. Menach-chouivau is drawn from a fruit of the ſize of an almond, extremely good in liquors or meats. Menach-maſoutra is drawn from nuts, the fruit of the tree which produces dragon's blood. Menach-vourave is drawn from a fruit named *fontſi*. Menach-apocapouc is ſqueezed from the fruit apocapouc, extremely poiſonous. Menach-vintang is an oil from large acorns, or maſt. Menach-arame is drawn from nuts, the fruit of the tree from which the gum tacamahaca is produced.

Rock Oil. See PETROLEUM.

Eſſential Oil of Roſes. See ROSES.

Method of Purifying Rancid OILS. See CHEMISTRY, N° 1431.

OINTMENT, in pharmacy. See UNGUENT.

OKEHAM, the capital of Rutlandſhire, in England, ſeated in a rich and pleaſant valley, called the *vale of Catmus*. It is pretty well built, has a good church, a free-ſchool, and an hoſpital. W. Long. 0. 45. N. Lat. 52. 40.

OKINGHAM, OCKINGHAM, or *Woxingham*, a large town of Berkſhire, in England, noted for the manufacture of ſilk ſtockings. W. Long. 0. 50. N. Lat. 51. 26.

OLAUS MAGNUS. See MAGNUS.

OKRA. See HIBISCUS.

OLAX, in botany: A genus of the monogynia order, belonging to the triandria claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The calyx is entire; the corolla funnel-ſhaped and trifid; the nectarium tetraphyllous.

OLD AGE. See LONGEVITY. Many methods have been propoſed for lengthening life, and rendering old age comfortable. Cornaro's Treatiſe on this ſubject is known to every body, and needs not be quoted. To ſome of our readers the following ſet of reſolutions will perhaps be new, and may certainly be uſeful.

The old men ſhould reſolve, except the reaſons for a change be invincible, to live and to die in the public profeſſion of the religion in which they were born and bred. To avoid all profane talk and intricate debates on ſacred topics. To endeavour to get the better of the intruſions of indolence of mind and body, thoſe certain harbingers of enfeebling age. Rather to wear out, than to ruſt out. To riſe early, and as often as poſſible to go to bed before midnight. Not to nod in company, nor to indulge repoſe too frequently on the couch in the day. To waſte as little of life in ſleep as may be, for we ſhall have enough in the grave. Not to give up walking; nor to ride on horſeback to fatigue. Experience, and a late medical opinion, determine to ride five miles every day: Nothing contributes more to the preſervation of appetite, and the prolongation of life. Cheyne's direction to the valetudinary, "to make exerciſe a part of their religion," to be religiouſly obſerved. To continue the practice of reading, purſued for more than fifty years, in books on all ſubjects; for variety is the ſalt of the mind as well as of life. Other people's thoughts, like the beſt converſation of one's companions, are generally better and more agreeable than one's own. Frequently to think over the virtues of one's acquaintance, old and new. To admit every cheerful ray of ſunſhine on the imagination. To avoid retroſpection on a paſt friendſhip, which had much of love in it; for memory often comes when ſhe is not invited. To try to think more of the living and leſs of the dead; for the dead belong to a world of their own. To live within one's income, be it large or little. Not to let paſſion of any ſort run away with the underſtanding. Not to encourage romantic hopes nor fears. Not to drive away hope, the ſovereign balm of life, though he is the greateſt of all flatterers. Not to be under the dominion of ſuperſtition or enthuſiaſm. Not wilfully to undertake any thing for which the nerves of the mind or the body are not ſtrong enough. Not to run the race of competition, or to be in another's way. To avoid being joſtled too much in the ſtreet, being overcome by the noiſe of the carriages, and not to be carried even by curioſity itſelf into a large crowd. To ſtrive to embody that dignified ſentiment, "to write injuries in duſt, but kindneſſes in marble." Not to give the reins to conſtitutional impatience, for it is apt to hurry on the firſt expreſſions into the indecency of ſwearing. To recollect, that he who can keep his own temper may be maſter of another's. If one cannot be a ſtoic, in bearing and forbearing, on every trying occaſion, yet it may not be impoſſible to pull the check-ſtring againſt the moroſeneſs of ſpleen or the impetuoſity of peeviſhneſs. Anger is a ſhort madneſs. Not to fall in love, now on the precipice of threeſcore, nor expect to be fallen in love with. A connexion between ſummer and winter is an improper one. Love, like fire, is a good ſervant, but a bad maſter. Love is death, when the animal ſpirits are gone. To contrive to have as few vacant hours upon one's hands as poſſible, that idleneſs, the mother of crimes and vices, may not pay its viſit. To be always doing of ſomething, and to have ſomething to do. To fill up one's time, and to have a good deal to fill up: for time is the materials that life is made of. If one is not able by ſituation, or through the neceſſity of raiſing the ſupplies within the year, or by habit (for virtue itſelf is but habit), to do much oſtentatious good, yet do as little harm as poſſible. To make the beſt and the moſt of every thing. Not to indulge too much in the luxury of the table, nor yet to underlive the conſtitution. The gout, rheumatiſm, and dropſy, in the language of the Spectator, ſeem to be hovering over the diſhes. Wine, the great purveyor of pleaſure, and the ſecond in rank among the ſenſes, offers his ſervice, when love takes his leave. It is natural to catch hold of every help, when the ſpirits begin to droop. Love and wine are good cordials, but are not proper for the beverage of common uſe. Reſolve not to go to bed on a full meal. A light ſupper and a good conſcience are the beſt receipts for a good night's reſt, and the parents of undiſturbing dreams. Not to be enervated by the flatulency of tea. Let the ſecond [illegible] third morning's thought be to conſider of the employment for the day; and one of the laſt at night to inquire what has been done in the courſe of it. Not to let one's tongue run at the expence of truth. Not to be too communicative nor unreſerved. A cloſe tongue, with an open countenance, are the ſafeſt paſſports through the journey of the world. To correct the error of too much talking, and reſtrain the narrativeneſs of the approaching climacteric. To take the good-natured ſide in converſation. However, not to praiſe every body, for that is to praiſe nobody. Not to be inquiſitive, and eager to know ſecrets, nor be thought to have a head full of other people's affairs. Not to make an enemy, nor to loſe a friend. To aim at the eſteem of the public, and to leave a good name behind. Not to be ſingular in dreſs, in behaviour, in notions, or expreſſions of one's thoughts. Never to give bad advice, and to ſtrive not to ſet a bad example. Seldom to give advice till aſked, for it appears like giving ſomething that is ſuperfluous to one's ſelf. Not to like or diſlike too much at firſt ſight. Not to wonder, for all wonder is ignorance that poſſeſſion falls ſhort of expectation. The longing of twenty years may be diſappointed in the unanſwered gratification of a ſingle hour. Whilſt we are wiſhing, we ſee the beſt ſide; after we have taken poſſeſſion, the worſt. Reſolve to attend to the arguments on both ſides, and to hear every body againſt every body. The mind ought not to be made up, but upon the beſt evidence. To be affectionate to relations, which is a kind of ſelf-love, in preference to all other acquaintance. But not to omit paying the commanding reſpect to merit, which is ſuperior to all the accidental chains of kindred. Not to debilitate the mind by new and future compoſitions. Like the ſpider, it may ſpin itſelf to death. The mind, like the field, muſt have its fallow ſeaſon. The leiſure of the pen has created honourable acquaintance, and pleaſed all it has wiſhed to pleaſe. To reſolve not to be too free of promiſes, for performances are ſometimes very difficult things. Not to be too much alone, nor to read, nor meditate, or talk too much on points that may awaken tender ſenſations, and be too pathetic for the ſoul. To enjoy the preſent, not to be made too unhappy by reflection on the paſt, not to be oppreſſed by invincible gloom on the future. To give and receive comfort, thoſe neceſſary alms to a diſtreſſed mind. To be conſtantly thankful to Providence for the plenty hitherto poſſeſſed, which has preſerved one from the dependence on party, perſons, and opinions, and kept one out of debt. The appearance of a happy ſituation, and opportunities of taſting many worldly felicities (for content has ſeldom perverted itſelf into diſcontent), has induced many to conclude, that one muſt be pleaſed with one's lot in life; and it occaſions many to look with the eye of innocent envy. To reſolve more than ever to ſhun every public ſtation and reſponſibility of conduct. To be ſatisfied with being maſter of one's ſelf, one's habits, now a ſecond nature, and one's time. Determined not to ſolicit, unleſs trampled upon by fortune, to live and die in the harneſs of trade, or a profeſſion. To take care that pity (humanity is not here meant) does not find out one in the endurance of any calamity. When pity is within call, contempt is not far off. Not to wiſh to have a greater hold of life, nor to quit that hold. The poſſible tenure of exiſtence is of too ſhort poſſeſſion for the long night that is to ſucceed: therefore not a moment to be loſt. Not to loſe ſight, even for a ſingle day, of theſe good and proverbial doctors—diet—merryman—and quiet. Reſolved to remember and to recommend, towards tranquillity and longevity, the three oral maxims of Sir Hans Sloane —"Never to quarrel with one's ſelf—one's wife—or one's prince." Laſtly, Not to put one's ſelf too much in the power of the elements, thoſe great enemies to the human frame; namely, the ſun—the wind—the rain—and the night air.

Old Man of the Mountain. See **Assassins.**

OLDCASTLE (Sir John), called the *Good Lord Cobham*, was born in the reign of Edward III. and was the firſt author as well as the firſt martyr among the Engliſh nobility: he obtained his peerage by marrying the heireſs of that Lord Cobham who with ſo much virtue and patriotiſm oppoſed the tyranny of Richard II. By his means the famous ſtatute againſt proviſors was revived, and guarded againſt by ſeverer penalties; he was one of the leaders of the reforming party; was at great expence in procuring and diſperſing copies of Wickliffe's writings among the people, as well as by maintaining a number of his diſciples as itinerant preachers. In the reign of Henry V. he was accuſed of hereſy; the growth of which was attributed to his influence. Being a domeſtic in the king's court, the king delayed his proſecution that he might reaſon with him himſelf; but not being able to reclaim him to the church of Rome, he in great diſpleaſure reſigned him to its cenſure. He was apprehended and condemned for hereſy; but eſcaping from the Tower, lay concealed for four years in Wales, until the rumour of a pretended conſpiracy was raiſed againſt him, and a price ſet upon his head: he was at laſt ſeized, and executed in St Giles's Fields; being hung alive in chains upon a gallows, and burned by a fire placed underneath. He wrote "Twelve Concluſions, addreſſed to the Parliament of England."

OLDENBURG, a title of the royal houſe of Denmark. The origin of this illuſtrious family, we are told, is this:—

On the death of Chriſtopher king of Denmark, &c. in 1448, without iſſue, there was a great conteſt about the ſucceſſion; and a variety of factions were raiſed, particularly in Sweden and Norway, for the promotion of different perſons; and various animoſities and numerous diſcords were excited by the ſeveral parties, in order each to obtain their own ends.

As ſoon as theſe intrigues were known in Denmark, the ſenate reſolved to proceed to the election of a king; for it did not appear expedient to commit the government of affairs to the queen dowager at a time when they had every thing to fear from the two neighbouring crowns. At this time a lord of great weight, property, and ambition, ſought the queen in marriage, the more eaſily to pave his way to the throne. This is a fact mentioned by Pontanus and Meurſius, though neither takes notice of his name. But as for a great number of years there was no precedent for electing a king out of the body of nobility, though agreeable to law, the queen entered into the views of the ſenate, and declared ſhe would give her hand to no prince who ſhould not be judged deſerving of the crown by the ſupreme council of the nation.

The advantages which would have accrued from annexing the duchy of Sleſwick and Holſtein to the crown, made the ſenate firſt caſt their eye [illegible] Adolphus. This matter required no long deliberation; all ſaw the conveniences reſulting from ſuch an union, and gave their aſſent. Immediately an embaſſy was deſpatched with the offer to Adolphus; but that prince conſulting the good of his ſubjects, whoſe intereſt would have been abſorbed in the ſuperior weight of Denmark, declined it, with a moderation and diſintereſtedneſs, altogether uncommon among princes. However, that he might not be wanting in reſpect to the ſenate, he propoſed to them his nephew Chriſtian, ſecond ſon to Theodoric, count of Oldenburg, a prince bred up at the court of Adolphus from his infancy. The propoſition was ſo agreeable to the ſenate, that, without loſs of time, the ambaſſadors were ſent to Theodoric, to demand either of his ſons he ſhould pitch upon for their king. Theodoric's anſwer to the ambaſſadors was remarkable: "I have three ſons, ſays he, of very oppoſite qualities. One is paſſionately fond of pleaſure and women; another breathes nothing but war, without regarding the juſtice of the cauſe; but the third is moderate in his diſpoſition, prefers peace to the din of arms, yet ſtands unrivalled in valour, generoſity, and magnanimity." He ſaid he painted theſe characters for the ſenate's information, deſiring they would chooſe which of the young princes they believed would render the kingdom happieſt. It wa[illegible] matter which would admit of no heſitation: with one voice the ſenate declared for that prince whoſe panegyric the father had ſo warmly drawn; and under theſe happy auſpices commenced the origin of the grandeur of the houſe of Oldenburg, at this day ſeated on the throne of Denmark.

Oldenburg (Henry), a learned German gentleman in the 17th century, was deſcended from the noble family of his name, who were earls of the county of Oldenburg, in the north part of Weſtphalia, for many generations. He was born in the duchy of Bremen in the Lower Saxony; and during the long Engliſh parliament in King Charles I.'s time, was appointed conſul for his countrymen, at London, after the uſurpation of Cromwell: but being diſcharged of that employ, he was made tutor to the lord Henry O'Bryan, an Iriſh nobleman, whom he attended to the univerſity of Oxford, where he was admitted to ſtudy in the Bodleian library in the beginning of the year 1656. He was afterwards tutor to William lord Cavendiſh, and was acquainted with Milton the poet. During his reſidence at Oxford, he became alſo acquainted with the members of that body there which gave birth to the Royal Society; and upon the foundation of this latter, he was elected fellow; and when the ſociety found it neceſſary to have two ſecretaries, he was choſen aſſiſtant ſecretary to Dr Wilkins. He applied himſelf with extraordinary diligence to the buſineſs of his office, and began the publication of the Philoſophical Tranſactions with N° I. in 1664. In order to diſcharge this taſk with greater credit to himſelf and the ſociety, he held a correſpondence with more than ſeventy learned perſons, and others, upon a vaſt variety of ſubjects, in different parts of the world. This fatigue would have been inſupportable, had not he, as he told Dr Liſter, managed it ſo as to make one letter anſwer another; and that to be always freſh, he never read a letter before he had pen, ink, and paper, ready to anſwer it forthwith; ſo that the multitude of his letters cloyed him not, nor ever lay upon his hands. Among others, he was a conſtant correſpondent of Mr Robert Boyle, with whom he had a very intimate friendſhip; and he tranſlated ſeveral of that ingenious gentleman's works into Latin.

Mr Oldenburg continued to publiſh the Tranſactions, as before, to N° XXXVI. June 25. 1677. After which the publication was diſcontinued till the January following, when it was again reſumed by his ſucceſſor in the ſecretary's office, Mr Nehemiah Grew, who carried it on till the end of February 1678. Our author dying at his houſe at Charleton, near Greenwich in Kent, in the month of Auguſt that year, was interred there.

OLDENLANDIA, in botany: A genus of the tetrandria monogynia claſs. Its characters are theſe: The empalement of the flower is permanent, ſitting upon the germen; the flower has four oval petals, which ſpread open, and four ſtamina, terminated by ſmall ſummits; it hath a roundiſh germen, ſituated under the flower, crowned by an indented ſtigma; the germen afterwards turns to a globular capſule, with two cells filled with ſmall ſeeds. We have but one ſpecies of this plant in the Engliſh gardens: but Linnæus enumerates ſix.

OLDHAM (John), an eminent Engliſh poet in the 17th century, ſon of a Nonconformiſt miniſter, was educated under his father, and then ſent to Edmund-hall in Oxford. He became uſher to the free-ſchool at Croydon in Surry; where he received a viſit from the earls of Rocheſter and Dorſet, Sir Charles Sedley, and other perſons of diſtinction, merely upon the reputation of ſome verſes of his which they had ſeen in manuſcript. He was tutor to ſeveral gentlemen's ſons ſucceſſively; and having ſaved a ſmall ſum of money, came to London, and became a perfect votary to the bottle, being an agreeable companion. He was quickly found out here by the noblemen who had viſited him at Croydon, who brought him acquainted with Mr Dryden. He lived moſtly with the earl of Kingſton at Holme-Pierpoint in Nottinghamſhire, where he died of the ſmallpox in 1683, in the 30th year of his age. His acquaintance with learned authors appears by his ſatires againſt the Jeſuits, in which there is as much learning as wit diſcovered. Mr Dryden eſteemed him highly. His works are printed in 2 vols. 12mo. They chiefly conſiſt of ſatires, odes, tranſlations, paraphraſes of Horace and other authors, elegiac verſes, imitations, parodies, familiar epiſtles, &c.

OLD-HEAD, ſituated in the county of Cork, and province of Munſter, four miles ſouth of Kinſale, in the barony of Courcies, Ireland: it is a promontory, running far into the ſea, on which is a lighthouſe for the convenience of ſhipping. A mile from its extremity is an ancient caſtle of the lords of Kinſale, built from one ſide of the iſthmus to the other, which defended all the lands towards the head: this place was formerly called *Duncearma*, and was the old ſeat of the Iriſh kings. The iſthmus, by the working of the ſea, was quite penetrated through, ſo as to form a ſtupendous arch, under which boats might paſs from one bay to the other. Among the rocks of this coaſt there are aviaries of good hawks; alſo the ſea eagles or oſpreys build their neſts and breed them.

OLDMIXON (John), was deſcended from an ancient family in Somerſetſhire: he was a violent party-writer and malevolent critic, who would ſcarcely have been remembered, if Pope, in reſentment of his abuſe, had not condemned him to immortality in his Dunciad. His party-writings procured him a place in the revenue at Liverpool, where he died at an advanced age in the year 1745. Beſides his fugitive temporary pieces, he wrote a Hiſtory of the Stuarts, in folio; a Critical Hiſtory of England, 2 vols. 8vo; a volume of Poems, ſome dramatic pieces, &c.; none of them worthy of notice, his principal talent being that of falſifying hiſtory.

Old-wife, or *Wraſſe*. See Labrus.

Old-wife *Fiſh*. See Baliſtes.

Old-woman's island, a narrow ſlip of land, about two miles long, ſeparated from Bombay in the Eaſt Indies by an arm of the ſea, which, however, is paſſable at low water. It terminates at one extremity in a ſmall eminence, on which a look-out houſe is kept for veſſels. Near the middle are three tombs kept conſtantly white, as land-marks into the harbour. From the end of the iſland a dangerous ledge of rocks ſhoots forth, which are not very eaſily cleared. It produces only paſture for a few cattle.

OLEA, in botany, the *olive-tree*: A genus of the monogynia order, belonging to the diandria claſs of plants; and in the natural method ranking under the 44th order, *Sepiariæ*. The corolla is quadrifid, with the ſegments nearly ovate. The fruit is a monoſpermous plum.

There are three ſpecies of the olea. 1. The *Europea*, or common olive tree, riſes with upright ſolid ſtems, branching numerouſly on every ſide, 20 or 30 feet high; ſpear-ſhaped, ſtiff, oppoſite leaves, two or three inches long, and half an inch or more broad; and at the axillas ſmall cluſters of white flowers, ſucceeded by oval fruit.

This ſpecies is the principal ſort cultivated for its fruit; the varieties of which are numerous, varying in colour, and quality.

It is a native of the ſouthern warm parts of Europe, and is cultivated in great quantities in the ſouth of France, Italy, and Portugal, for the fruit to make the olive oil, which is in ſo great repute, and is tranſported to all parts, to the great advantage of thoſe countries where the trees grow in the open ground: the green fruit is alſo in much eſteem for pickling, of which we may ſee plenty in the ſhops.

2. The *capenſis*, or cape box-leaved olive, riſes with ſhrubby ſtems, branching numerouſly from the bottom, ſix or ſeven feet high; ſmall, oval, thick, ſtiff, ſhining leaves; and at the axillas ſmall cluſters of whitiſh flowers, ſucceeded by ſmall fruit of inferior value.

3. *Olea odoratiſſima* (Indian name, *queſa;* Japaneſe name, *Skio Ran, it: Sju Ran*) is thus deſcribed by Thunberg, *bulbis fibroſis, foliis enſiformibus, ſeſſilibus, floribus pendulis.* (See Plate CCCXLIX.) The flower of the olea odoratiſſima is by ſome ſaid to give the fine flavour to the green tea; but Thunberg attributes the ſaid flavour to the *Cemellie ſeſerque.*

Olive trees are eaſily propagated by ſhoots; which, when care has been taken to ingraft them properly, bear fruit in the ſpace of eight or ten years. Thoſe kinds of olive trees which produce the pureſt oil, and bear the greateſt quantity of fruit, are ingrafted on the ſtocks of inferior kinds.

Different names are aſſigned by the French to the different varieties of the olive tree; and of theſe they reckon 19, whilſt in Florence are cultivated no fewer than 32.

Olive ſhoots are ingrafted when in flower. If the operation has been delayed, and the tree bears fruit, it is thought ſufficient to take off a ring of bark, two fingers breadth in extent, above the higheſt graff. In that caſe the branches do not decay the firſt year; they afford nouriſhment to the fruit, and are not lopped off till the following ſpring. Olive trees are commonly planted in the form of a quincunx, and in rows at a conſiderable diſtance from one another. Between the rows is is uſual to plant vines, or to ſow ſome kind of grain. It is obſerved, that olives, like many other fruit trees, bear well only once in two years. The whole art of dreſſing theſe trees conſiſts in removing the ſuperfluous wood; for it is remarked, that trees loaded with too much wood produce neither ſo much fruit nor of ſo good a quality.

Their propagation in England is commonly by layers.

The laying is performed on the young branches in ſpring. Give plenty of water all ſummer, and they will ſometimes be rooted and fit for potting off in autumn; but ſometimes they require two ſummers to be rooted effectually: when, however, they are properly rooted, take them off early in autumn, and pot them ſeparately: give water, and place them in the ſhade till they have taken freſh root; and in October remove them into the green-houſe, &c.

Thoſe you intend to plant in the open ground, as before ſuggeſted, ſhould be kept in pots, in order to have occaſional ſhelter of a garden frame two or three years, till they have acquired ſome ſize, and are hardened to the full air; then tranſplant them into a warm border againſt a wall: mulch their roots in winter, and mat their tops in froſty weather.

Olives have an acrid, bitter, extremely diſagreeable taſte: pickled (as we receive them from abroad) they prove leſs diſagreeable. The Lucca olives, which are ſmaller than the others, have the weakeſt taſte; the Spaniſh, or larger, the ſtrongeſt; the Provence, which are of a middling ſize, are generally the moſt eſteemed.

When olives are intended for preſervation, they are gathered before they are ripe. The art of preparing them conſiſts in removing their bitterneſs, in preſerving them green, and in impregnating them with a brine of aromatized ſea ſalt, which gives them an agreeable taſte. For this purpoſe different methods are employed. Formerly they uſed a mixture of a pound of quicklime, with ſix pounds of newly ſifted wood aſhes; but of late, inſtead of the aſhes, they employ nothing but a lye. This, it is alleged, ſoftens the olives, makes them more agreeable to the taſte, and leſs hurtful to the conſtitution. In ſome parts of Provence, after the olives have lain ſome time in the brine, they remove them, take out the kernel, and put a caper in its place. Theſe olives they preſerve in excellent oil; and when thus prepared, they ſtrongly ſtimulate the appetite in winter. Olives perfectly ripe are ſoft and of a dark red colour. They are then eaten without any preparation, excepting only a ſeaſoning of pepper, ſalt, and oil; for they are extremely tart, bitter, and corroſive.

The oil is undoubtedly that part of the produce of olive trees which is of greateſt value. The quality of it depends on the nature of the ſoil where the trees grow, on the kind of olive from which it is expreſſed, on the care which is taken in the gathering and preſſing of the fruit, and likewiſe on the ſeparation of the part to be extracted. Unripe olives give an intolerable bitterneſs to the oil; when they are over ripe, the oil has an unguinous taſte: it is therefore of importance to chooſe the true point of maturity. When the ſituation is favourable, thoſe ſpecies of olives are cultivated which yield fine oils; otherwiſe, they cultivate ſuch ſpecies of trees as bear a great quantity of fruit, and they extract oil from it, for the uſe of ſoaperies, and for lamps.

They gather the olives about the months of November or December. It is beſt to put them as ſoon as poſſible into baſkets, or into bags made of wool or hair, and to preſs them immediately, in order to extract a fine oil. Thoſe who make oil only for ſoaperies, let them remain in heaps for ſome time in their ſtore houſes; when afterwards preſſed, they yield a much greater quantity of oil. Thoſe even who extract oil to be uſed in food, ſometimes allow them to ferment in heaps, that they may have more oil; but this is extremely hurtful to the quality of the oil, and is the reaſon why fine oil is ſo very rare. M. Duhamel recommends not to mix ſound olives with thoſe in which a fermentation has already begun, and ſtill leſs with ſuch as are putrified: in both caſes, the oil which is extracted is of a bad quality, and unfit for preſervation. In order to have the oil in its purity, we muſt allow it to depoſite its ſediment, and then pour it off into another veſſel. The oil extracted from the pulp only of olives is the moſt perfect which can be obtained, and will keep for ſeveral years; but that which

Olea.

Oleaginous ‖ Olearius.

is extracted from the kernel only, or from the nut, or from the whole olive ground in the common way in public mills, has always more or fewer defects, loſes its limpidity in a certain time, and is very apt to become rancid. Care muſt taken likewiſe to keep the oil in proper veſſels well ſhut. After all, in the courſe of time, olive oil loſes its qualities, becomes diſagreeable to the taſte and ſmell, diminiſhes in fluidity, and at length thickens conſiderably.

The refuſe of the firſt preſſing, when ſqueezed a ſecond time, yields an oil, but thicker and leſs pure than the former. What remains after the ſecond preſſing, when mixed with a little water and placed in a pan over the fire, produces by preſſure a third oil, but of a very inferior quality. What remains after all the oil is expreſſed, is termed *grignon*, and is of no farther uſe but as fuel.

The ſediment, or *fæces*, of new oil, we name after the ancients, *amurca*: it is an excellent remedy in rheumatic affections. In Paris the wax uſed for ſhoes is commonly made of the dregs of defecated oil and ſmoke-black.

Oil of olives is an ingredient in the compoſition of a great many balſams, ointments, plaſters, mollifying and relaxing liniments. It is of an emollient and ſolvent nature; mitigates gripes of the colic, and the pains accompanying dyſentery; and is one the beſt remedies when one has chanced to ſwallow corroſive poiſons; but it by no means prevents the fatal accidents which enſue from the bite of a ſnake, as has been pretended. It is an effectual cure, as M. Bourgeois tells us, for the ſting of waſps, bees, and other inſects. A bandage ſoaked in the oil is immediately applied to the ſting, and a cure is obtained without any inflammation or ſwelling.

Olive oil is of no uſe in painting, becauſe it never dries completely. The beſt ſoap is made of it, mixed with Alicant ſalt-wort and quicklime.

Great drought, as well as much rain, is extremely injurious to the crop of olives. This fruit is much expoſed to the attacks of a worm peculiar to itſelf, and which injures it ſo much, that after the olives are gathered the produce of the oil extracted from them is diminiſhed one half.

The wood of the olive tree is beautifully veined, and has a pretty agreeable ſmell: it is in great eſteem with cabinetmakers, on account of the fine poliſh which it aſſumes. It is of a reſinous nature, and conſequently excellent for burning.

As the laurel branch is the ſymbol of glory, ſo the olive branch covered with leaves has from the moſt ancient times been the emblem of concord, the ſymbol of friendſhip and peace.

The leaves of olive trees have an aſtringent quality. Many people uſe them in making gargles for inflammations of the throat.

Theſe plants in this country muſt be kept principally in pots for moving to the ſhelter of a green-houſe in winter; for they are too tender to proſper well in the open ground in this climate: though ſometimes they are planted againſt a warm ſouth wall, and ſheltered occaſionally from froſt in winter, by mulching the roots, and matting their tops; whereby they may be preſerved, and will ſometimes produce fruit for pickling: a very ſevere winter, however, often kills or greatly injures their young branches; therefore let the principal part be potted in rich earth, and placed among the green-houſe ſhrubs, and managed as others of that kind.

Theſe trees are often ſent over from Italy to the Italian warehouſes in London, along with orange-trees, &c. where pretty large plants may be purchaſed reaſonably, which ſhould be managed as directed for orange trees that are imported from the ſame country. See Citrus.

OLEAGINOUS, ſomething that partakes of the nature of oil, or out of which oil may be expreſſed.

OLEANDER, or rose bay, *nerium*: A genus of the pentandria monogynia claſs. Its characters are theſe: The empalement of the flower is permanent and cut into five acute ſegments; the flower has one funnel-ſhaped petal, cut into five broad obtuſe ſegments, which are oblique; it hath a nectarium, terminating the tube, which is torn into hairy ſegments; it hath five ſhort awl-ſhaped ſtamina within the tube; it hath an oblong germen, which is bifid, with ſcarce any ſtyle, crowned by ſingle ſtigmas; the germen afterwards turns to two long, taper, acute-pointed pods, filled with oblong ſeeds lying over each other like the ſcales of a fiſh, and crowned with down. There are four ſpecies.

Theſe plants are generally propagated by layers in this country; for although they will take root from cuttings, yet that being an uncertain method, the other is generally preferred; and as the plants are very apt to produce ſuckers or ſhoots from their roots, thoſe are beſt adapted for laying; for the old branches will not put out roots: when theſe are laid down, they ſhould be ſlit at a joint, in the ſame manner as is practiſed in laying of carnations. There are few plants which are equal to them either to the ſight or ſmell, for their ſcent is very like that of the flowers of the white thorn; and the bunches of flowers will be very large if the plants are ſtrong.

It is called *nerium* from *νηρος*, "humid," becauſe it grows in humid places. The plant itſelf has a force which is inſuperable; for its juice excites ſo great and violent an inflammation, as immediately to put a ſtop to deglutition; and if it be received into the ſtomach, that part is rendered incapable of retaining any thing; the pernicious drug exerting its force, and purging both upwards and downwards.

Nerium in qualities reſembles the apocynum. See Apocynum. But when handled and examined upon an empty ſtomach, in a cloſe chamber, it cauſes a numbneſs coming by degrees, with a pain in the head; which ſhows that ſomething poiſonous belongs even to the ſmell, though there is no danger if it be received in the open air as may be found upon trial. Antidotes againſt its poiſon are vinegar and all acids.

OLEARIUS (Adam), miniſter to the duke of Holſtein, and ſecretary to the embaſſy ſent in 1633 to the great duke of Muſcovy and to the king of Perſia. He ſpent ſix years in this employment: and, on his return, publiſhed a relation of his journeys, with maps and figures, at Sleſwic, 1656, in folio. He wrote an *Abridgment of the Chronicles of Holſtein from 1448 to 1663*; and was appointed librarian to the duke of Holſtein, in which capacity he probably died. He has the character of an able mathematician, an adept in muſic, and a good orientaliſt, eſpecially in the Perſian language.

Olearius (Godfrey), ſon of Godfrey Olearius, D. D. ſuperintendent of Halle in Saxony, was born there in 1639. He became profeſſor of Greek at Leipſic; and ſhowed his abilities in that language by 52 exercitations on the dominical epiſtles, and upon thoſe parts of the epiſtles in the New Teſtament which are read in the public exerciſes, and which among the Lutherans are the ſubject of part of their ſermons. He diſcharged the moſt important poſts in the univerſity, and among other dignities was ten times rector of it. His learning and induſtry were diſplayed in 106 theological diſputations, 61 in philoſophy, ſome programmas upon difficult points, ſeveral ſpeeches and theological counſels; which make two thick volumes: beſide his Moral Theology, his introduction to Theology, which treats of caſes of conſcience, and his *Hermeneutica Sacra.* He lived to a good old age, dying in 1713. His eldeſt ſon of his own name was a man of genius and learning, a profeſſor in the ſame univerſity, who publiſhed ſeveral works, but died young of a conſumption before his father.

OLECRANUM, or Olecranon, in anatomy, the protuberance of the ulna, which prevents the joint of the elbow from being bent back beyond a certain length. See Anatomy, N° 51.

OLENUS, a Greek poet, older than Orpheus, came from Xanthe, a city of Lycia. He compoſed ſeveral hymns, which were ſung in the iſland of Delos upon feſtival days. Olenus is ſaid to have been one of the founders of the oracle at Delphi; to have been the firſt who filled at that place the office of prieſt of Apollo; and to have given reſponſes in verſe: but the truth of theſe aſſertions is very doubtful.

OLERON, an iſland of France, on the coaſt of Aunis and Saintonge, about five miles from the continent. It is 12 miles in length, and five in breadth; and is very fertile, containing about 12,000 inhabitants, who are excellent ſeamen. It is defended by a caſtle, which is well fortified; and there is a lighthouſe placed there for the direction of ſhips. It is 14 miles ſouth-eaſt of Rochelle. W. Long. 1. 26. N. Lat. 46. 10.

Sea Laws of Oleron, certain laws relative to maritime affairs, made in the time of Richard I. when he was at the iſland of Oleron. Theſe laws, being accounted the moſt excellent ſea laws in the world, and recorded in the black book of the admiralty. See *Selden's Mare Clauſum.*

OLEUM palmæ christi, commonly called *caſtor oil,* is extracted from the kernel of the fruit produced by the *Ricinus Americanus.* (See Ricinus). This oil has been much uſed as a purgative in medicine. It acts gently on the bowels, with little or no irritation. By many phyſicians it has been deemed a ſovereign remedy in bilious, calculous, and nephritic complaints; but its taſte is extremely nauſeous, and, when frequently uſed, it is apt to relax the tone of the bowels. It is recommended to be given in clyſters; and Dr Canvane of Bath affirms, that when children cannot be made to ſwallow any medicine, if the navel and hypochondria be rubbed with this oil, it will produce one or two phyſical ſtools. He adds, that given in ſmall draughts, or by clyſter, or by embrocation, it is an excellent and wonderful vermifuge.

OLFACTORY nerves. See Anatomy, N° 136 and 140.

OLGA, queen of Igor the ſecond monarch of Ruſſia, who flouriſhed about the year 880, having ſucceeded his father Ruric, who died in 878. Olga was born in Pleſcow, and was of the beſt family in that city. She bore him one ſon, called *Swetoſlaw.* Igor being murdered by the Drewenſes, or Drewliani, Olga revenged his death. She went afterwards, for what reaſon we know not, to Conſtantinople, where ſhe was baptized, and received the name of *Helena.*

The emperor John Zimiſces was her godfather, and fell in love with her as we are told; but ſhe, alleging their ſpiritual alliance, refuſed to marry him. Her example made ſome impreſſion upon her ſubjects, a good number of whom became converts to Chriſtianity; but none upon her ſon, who reigned for a long time after her death, which happened at Pereſlaw, in the 80th year of her age, 14 years after her baptiſm. The Ruſſians to this day rank her among their ſaints, and commemorate her feſtival on the 11th of July.

OLIBANUM, in pharmacy, a gummy reſin, the product of the *juniperus lycia* (Lin.), brought from Turkey and the Eaſt Indies, uſually in drops or tears like thoſe of maſtich, but larger; of a pale yellowiſh, and ſometimes reddiſh, colour; a moderately warm pungent taſte, and a ſtrong, not very agreeable ſmell. This drug has received many different appellations, according to its different appearances: the ſingle tears are called ſimply *olibanum* or *thus;* when two are joined together, they have been called *thus maſculum,* and when very large, *thus fœmininum:* ſometimes four or five, about the bigneſs of filberds, are found adhering to a piece of the bark of the tree which they exuded from; theſe have been named *thus corticoſum:* the finer powder which rubs off from the tears in the carriage, *mica thuris;* and the coarſer powder, *manna thuris.* This drug is not however, in any of its ſtates, what is now called *thus* or *frankincenſe* in the ſhops. See the article Thus.

Olibanum conſiſts of about equal parts of a gummy and reſinous ſubſtance; the firſt ſoluble in water, the other in rectified ſpirit. With regard to its virtues, abundance have been attributed to it, particularly in diſorders of the head and breaſt, in hæmoptoes, and in alvine and uterine fluxes: but its real effects in theſe caſes are far from anſwering the promiſes of the recommenders. Riverius is ſaid to have had large experience of the good effects of this drug in pleuriſies, eſpecially epidemic ones: he directs a ſcooped apple to be filled with a dram of olibanum, then covered and roaſted under the aſhes; this is to be taken for a doſe, three ounces of carduus water after it, and the patient covered up warm in bed; in a ſhort time, he ſays, either a plentiful ſweat, or a gentle diarrhœa, enſues, which carry off the diſeaſe. Geoffroy informs us, that he has frequently made uſe of this medicine after veneſection, with good ſucceſs; but acknowledges that it has ſometimes failed.

OLIGÆDRA, in natural hiſtory, the name of a genus of cryſtals compoſed of very few planes, as the name expreſſes. The word is compounded of ολιγος "a few,"

few," and ἑδρα "a plane." The bodies of this claſs are cryſtals of the imperfect kind; being compoſed of columns affixed irregularly to ſome ſolid body at one end, and the other terminated by a pyramid: but the column and pyramid being both pentangular, the whole conſiſts only of ten planes, and not, as the common kind, of 12.

OLIGARCHY, a form of government wherein the adminiſtration of affairs is confined to a few hands.

OLIO, or Oglio, a ſavoury diſh, or food, compoſed of a great variety of ingredients; chiefly found at Spaniſh tables.

The forms of olios are various. To give a notion of this ſtrange aſſemblage, we ſhall here add one from an approved author.

Take rump of beef, neats tongues boiled and dried, and Bologna ſauſages; boil them together, and, after boiling two hours, add mutton, pork, veniſon and bacon, cut in bits; as alſo turnips, carrots, onions, and cabbage, borage, endive, marigolds, ſorrel, and ſpinach; then ſpices, as ſaffron, cloves, mace, nutmeg, &c. This done, in another pot put a turkey or gooſe, with capons, pheaſants, wigeons, and ducks, partridges, teals, and ſtock-doves, ſnipes, quails, and larks, and boil them in water and ſalt. In a third veſſel, prepare a ſauce of white wine, ſtrong broth, butter, bottoms of artichokes, and cheſnuts, with cauliflowers, bread, marrow, yolks of eggs, mace, and ſaffron. Laſtly, Diſh the olio, by firſt laying out the beef and veal, then the veniſon, mutton, tongues, and ſauſages, and the roots over all; then the largeſt fowls, then the ſmalleſt, and laſtly pour on the ſauce.

OLISIPO, (Pliny, Antonine, Inſcriptions); a town of Luſitania, ſituated on the north ſide of the frith of the Tagus; of ſuch antiquity, that Solinus thought it was built by Ulyſſes; and Mela, probably to favour this opinion, writes, according to the common copies, *Ulyſſipo*; both of them perhaps deceived by the ſimilarity of ſound. It was a municipium, with the ſurname *Felicitas Julia*, a privilege granted by the munificence of Auguſtus, (Inſcriptions, Pliny). Now Liſbon, capital of Portugal, ſituated on the north bank of the Tagus, diſtant about ten miles from its mouth. See Lisbon.

OLIVAREZ (Count de), by name *Don Gaſpar de Guzman*, favourite and miniſter to Don Philip IV. of Spain, about 1620; a man of great parts and boundleſs ambition. Philip no ſooner became king, than he became the ſubject of this his favourite. The king had abilities, it is true, but they lay dormant; and whilſt he ſpent his time in liſtleſs inactivity, the whole government was under the direction of Olivarez. The count's management, indeed, was ſufficiently dexterous in accompliſhing his own deſigns; for by the beſt framed excuſes, and on the moſt plauſible pretexts, he removed all ſuch as he thought ſtood in his way; nor did he ſtop there, but ſometimes perſecuted his rivals even to death, of which Don Rodrigo Calderona was a melancholy inſtance, an inſtance which at that time excited univerſal compaſſion. This miniſter, in ſhort, had a genius of no common kind; added to which, he had a diſpoſition which ſpurned all controul.

He had perſecuted the late miniſtry for their puſillanimity in the management of affairs; he therefore thought it neceſſary, and it was certainly prudent, to purſue new meaſures. His ſelf-ſufficiency, though unbounded, was concealed under the veil of aſſumed modeſty, and he was careful to make it appear that he was wholly taken up with the things of his own province. His politics were of a refined perhaps, but not of a very uſeful, tendency; for his imprudence, or his wrong notions on the ſubject, made him renew a war with Holland, contrary to the univerſal opinion of the council and the people. By the ſame imprudence, or by ſomething worſe, he provoked England, and obliged her to endeavour to humble the pride and leſſen the authority of the houſe of Auſtria. Thus far he had been of little ſervice to his country, having only provoked the reſentment of the moſt powerful ſtates, particularly England, France, Holland, &c. to conſpire for its ruin. It is remarkable that Olivarez, notwithſtanding this, never loſt his credit; and indeed things ſo turned about in the end, that though Spain for a whole year was put to the ſevereſt trials, it acquired a degree of fame which ſufficiently, in the general opinion, overbalanced ſome little loſs. Olivarez too was particularly fortunate in making the peace; in which tranſaction he gained a very conſiderable advantage over Richelieu, ſo that things appeared to be ſtill in a very favourable train. Fortune, however, was not always quite ſo indulgent to the ſchemes of this miniſter: he again drew Spain into a war with Mantua, contrary to the ſentiments of the wiſeſt men; from which is juſtly dated its declenſion, if not its ruin.

On the whole, Olivarez ſeems to have been always averſe to peace; and with ſuch a reſtleſs diſpoſition, it is undoubtedly wonderful that he held his place ſo long and with ſo few complaints as he did.

It was certainly owing to his ambition and obſtinacy, that an almoſt general war was excited about the year 1627, and which, as we have ſaid, proved ſo fatal to Spain. So averſe, indeed, does he appear to have been to peace, that he uſed every means in his power to prevent the reſtoration of it in Italy; and for this very purpoſe he ſent Feria into Milan, whom he knew to be a man of ſuch a temper and abilities as ſuited his purpoſes; for he was naturally averſe to quiet. He endeavoured to break the alliances of the duke of Mantua by various ſtratagems; but they did not ſucceed: the ſchemes of Olivarez and the intrigues of Feria being totally defeated. Our miniſter had ſoon after this another cauſe of mortification, on Richelieu's being created a duke and peer of France, and unanimouſly admitted among the Venetian nobility; which could not fail to be a ſevere ſtroke on Olivarez, who conſidered him as his implacable enemy.

The people at length began to ſee and to be diſpleaſed with his conduct; and with reaſon, had they known it all, for it was in many inſtances cruel and deteſtable. Indeed the differences which at that time had ſo long ſubſiſted between France and Spain were the effect of the private animoſity between him and Richelieu. Things, however, ſo turned about, and Spain was ſo unuſually ſucceſsful, that the faults of the miniſter were overlooked for the time; but this unexpected good fortune had no other effect than that of making him

him far more inſolent than ever. He was, in every inſtance, one of the moſt headſtrong and obſtinate men in the world: he had ſet his heart on the reduction of Caſal in Italy, and he was determined on it at whatever hazard; this fooliſh enterpriſe was, however, unaccountably defeated, and the Spaniſh army experienced a total defeat.

The revolt of the Catalans, whom he wiſhed to deprive of their privileges, was the next conſequence of his folly? he had privately employed the Marquis de los Velez to extinguiſh this rebellion; but the cruelty of the meaſures uſed for this purpoſe only inflamed it the more. The revolution of Portugal, another diſaſtrous event, was alſo the reſult of his obſtinacy and rigour.

This ſeries of ill fortune, which ought to have opened the eyes of the Catholic king and his miniſters, ſeemed to infatuate both. The great ſecret by which Olivarez had governed his maſter was being the companion, or at leaſt the confidant, of his pleaſures. While he affected to deceive the world with a ſpecious appearance of religion and piety, he was not only immerſed in vice himſelf, but encouraged and promoted it in his prince, to the ſcandal of his ſubjects, and the prejudice of his affairs. At this time, of all others the moſt improper, Olivarez produced a baſtard of his, hitherto called *Julian;* he had taken ſo little care of this ſon, that, not able to ſubſiſt in Spain he had paſſed over to the Indies, where, in very mean ſtations, he had ſcarce got bread. On him he now beſtowed the name of *Don Henrico de Guzman;* and bringing him with great pomp and ſplendour to court, either flattered or forced the conſtable of Caſtile to give him his daughter; in conſideration of which alliance he was to devolve upon him his duchy of St Lucar. In the beginning of his adminiſtration, by ſome accident or other, he preſented to the king a memorial, in relation to an affair upon which his majeſty had already received one from Don Balthaſar de Zuniga: upon comparing them, they contradicted each other flatly. The king ordered a a perſon of great quality to inquire thoroughly into this buſineſs; in conſequence of which Don Balthaſar's memorial appeared to be the truth, and that of Olivarez the reverſe of it. The king was very angry; but the count regained his favour, by procuring for him the fair actreſs Calderona. By this woman he had a ſon, of whom no great notice was taken; but now, to obſcure the folly of the count duke, this youth, ſcarce in the 14th year of his age, was produced, with the title of *Don Juan of Auſtria,* and declared generaliſſimo of the army againſt Portugal; while the heir apparent to the crown, Don Balthaſar, was left under the tuition, or rather in the cuſtody of the counteſs of Olivarez; at which conduct the queen was chagrined, the people enraged, and the world in general aſtoniſhed.

His ſchemes now began to be entirely broken and defeated everywhere and in every kind; he fell under the diſpleaſure of the queen, the emperor, the grandees, and the people all at once, and experienced the diſgrace he had long merited. His ill fortune, which came upon him with the force of a torrent, did not, however, wholly overpower him; he was indeed obliged to conceal himſelf, in order to avoid the rage of the populace: but he had ſtill confidence enough to offer an apology for his conduct, which poſſeſſed no inconſiderable ſhare of wit and humour, well tempered with ſpirit and maſterly reaſoning. It was not, however, of any conſequence to him; for he was baniſhed to Toro, where, worn out by infirmities, or overcome by deſpair, he ended his days about the year 1645.

OLIVE, in botany. See OLEA.

Plate CCCXLVII.

Olive Preſs. In order to obtain the olive oil, the olives are firſt bruiſed in a rough trough, under a millſtone, rolling perpendicularly over them; and when ſufficiently maſhed, put into the maye or trough, *m,* of an olive preſs, where *aa* are the upright beams, or cheeks; *b,* the female, and *c,* the male ſcrew; *f,* the board on which the ſcrew preſſes; *g,* a cubical piece of wood, called a *block; h,* the peel, a circular board, to be put under the block. By turning the ſcrew, all the liquor is preſſed out of the maſhed olives, and is called *virgin oil;* after which, hot water being poured upon the remainder in the preſs, a coarſer oil is obtained. Olive oil keeps only about a year, after which it degenerates.

Olive Colour, a yellow mingled with black.

OLIVE (Peter John), was born in France, and died in 1297, in the fiftieth year of his age. In his youth he wrote a book in praiſe of the Virgin Mary, which was condemned during the pontificate of Nicholas III. as containing ſome things too extravagant. He afterwards was frequently accuſed by the brothers of his order, whoſe reſentment he had drawn upon himſelf by his ſevere reproofs of their luxury, and his endeavours to recal them to the poverty and rigour of their firſt inſtitution. After his death his body was dug up, he was condemned as a heretic, and his writings were burnt, and remained prohibited till the time of Sixtus IV. who having ordered them to be examined, declared they contained nothing expreſsly contrary to the Catholic faith. The propoſitions condemned by John are mentioned by Emmericus, in his Directory of the Inquiſition, under twenty-two heads. The chief of them are, "That the Pope was the myſtical Antichriſt; that St Francis was the angel in the Revelation ſaid to have the mark of the living God, and that his rule was the true goſpel; that the perfect ſtate of the church began with St Francis; and that Chriſt and his apoſtles had no property, either in common or in particular, but only the uſufruct of what they enjoyed."

OLIVER (Iſaac), an excellent Engliſh painter, born in 1556, eminent both for hiſtory and portraits. Several fine miniatures of this maſter are to be ſeen in the collections of our nobility and gentry; ſome of them portraits of himſelf. As he was a very good deſigner, his drawings are finiſhed in an extraordinary degree of perfection; many being copies after Parmegiano. Rubens and Vandyck painted James I. after a miniature of Oliver's, which is a ſufficient teſtimony of his merit. He died in 1617.

OLIVER (Peter), the ſon and diſciple of Iſaac Oliver, was born in 1601. He arrived at a degree of perfection in miniature portaits confeſſedly ſuperior to his father, or any of his cotemporaries, as he did not confine his ſubjects to a head only. In the collections of Charles I. and James II. there were 13 hiſtorical ſubjects painted by this Oliver; of which ſeven are ſtill preſerved in the cloſet of Queen Caroline at Kenſington; and a capital painting of his wife is in the poſſeſſion of the ducheſs of Portland. He died in 1660.

OLIVET, or *Mount of Olives* (anc. geog.), was ſituated to the eaſt of the city of Jeruſalem, and parted from the city only by the brook Kidron, and by the valley of Jehoſhaphat, which ſtretches out from the north to the ſouth. It was upon this mount that Solomon built temples to the gods of the Ammonites (1 Kings xi. 7.) and of the Moabites, out of complaiſance to his wives, who were natives of theſe nations. Hence it is that the Mount of Olives is called the *mountain of corruption* (2 Kings xxiii. 13.) Joſephus ſays, that this mountain is at the diſtance of five ſtadia, or furlongs, from Jeruſalem, which make 625 geometrical paces, or the length of a Sabbath day's journey, ſays St Luke (Acts i. 12.) The Mount of Olives had three ſummits, or was compoſed of three ſeveral mountains, ranged one after another from north to ſouth. The middle ſummit is that from whence our Saviour aſcended into heaven. It was upon that towards the ſouth that Solomon built temples to his idols. The ſummit which is moſt to the north is diſtant two furlongs from the middlemoſt. This is the higheſt of the three, and is commonly called Galilee.

In the time of King Uzziah, the Mount of Olives was ſo ſhattered by an earthquake, that half of the earth that was on the weſtern ſide fell down, and rolled four furlongs or 500 paces from thence, towards the mountain which was oppoſite to it on the eaſt; ſo that the earth blocked up the highways, and covered the king's gardens.

Mr Maundrell tells us that he and his company going out of Jeruſalem at St Stephen's gate, and croſſing the valley of Jehoſhaphat, began immediately to aſcend the mountain; that being got above two-thirds of the way up, they came to certain grottos cut with intricate windings and caverns under ground, which were called the ſepulchres of the prophets; that a little higher up were twelve arched vaults under ground, ſtanding ſide by ſide, and built in memory of the apoſtles, who are ſaid to have compiled their creed in this place; that ſixty paces higher they came to the place where Chriſt is ſaid to have uttered his prophecy concerning the final deſtruction of Jeruſalem; and a little on the right hand, to another, where he is ſaid to have dictated a ſecond time the Lord's prayer to his diſciples; that ſomewhat higher is the cave of a ſaint called *Pelagia*; a little above that, a pillar denoting the place where an angel gave the Bleſſed Virgin three days warning of her death; and at the top of all, the place of our bleſſed Lord's aſcenſion.

OLIVETAN (Robert), related to the famous Calvin, printed at Neufchatel in 1535, in folio, a verſion of the Bible into French, the firſt which had been tranſlated from the original Hebrew and Greek. It is written in an uncouth and barbarous ſtyle, and is far from being faithful. The characters in which it is printed are Gothic, and the language of it is no leſs ſo. It is valued only becauſe it is rare to be found. Calvin is thought to have had a very conſiderable ſhare in this tranſlation. Olivetan ſurvived his publication but a ſhort time; for he was poiſoned at Rome the year after, of which his tranſlation is alleged to have been the cauſe. Olivetan's Bible, reviſed by John Calvin and N. Malinger, was reprinted at Geneva, in 1540, in quarto. This edition is ſtill rarer than the former. It is called the *Bible de l'Epée*, becauſe the printer had a ſword for his ſign.

OLIVIER (Claude Matthieu), advocate of the parliament of Aix, was born at Marſeilles in 1701, and appeared at the bar with eclat. He had a chief hand in the eſtabliſhment of the academy of Marſeilles, and was one of its original members. He poſſeſſed a quick and lively genius. A few hours retirement from ſociety and from his pleaſures were frequently ſufficient to enable him to ſpeak and write, even on important cauſes; but his works commonly bore marks of haſte. Given to exceſs in every thing, he would employ a fortnight in ſtudying the Code and the Digeſt, or in ſtoring his mind with the beauties of Demoſthenes, Homer, Cicero, or Boſſuet; and then abandon himſelf for another fortnight, frequently a whole month, to a life of frivolity and diſſipation. He died in 1736, at the age of 35. He publiſhed 1. *L'Hiſtoire de Philippe roi de Macedoine, et pere d'Alexandre le Grand*, 2 vols. 12mo. No writer has ſo ably handled the hiſtory of the age of Philip, the intereſts of the different nations of Greece, and their manners and cuſtoms: but the conduct of the work is extremely defective. The digreſſions are too frequent, and often tedious. The ſtyle is in no reſpect ſuitable to a hiſtory. It is in general dry, unconnected, and like the ſtyle of a diſſertation. Sometimes, however, we find in it paſſages full of fire and beauty, and turns of expreſſion truly original. A diſeaſe of the brain, with which he was attacked, and under which he laboured ſeveral years, prevented him from putting his laſt hand to the work. 2. *Mémoire ſur les ſecours donnés aux Romains par les Marſeillois pendant la 2de Guerre Punique.* 3. *Mémoire ſur les ſecours donnés aux Romains par les Marſeillois durant la Guerre contre les Gaulois.*

OLMUTZ, a town of Germany, in Moravia, with a biſhop's ſee, and a famous univerſity. The public buildings are very handſome, particularly the Jeſuits college. It is a populous, trading, and very ſtrong place; and yet it was taken, with the whole garriſon, by the king of Pruſſia in 1741. In July 1758 he beſieged it again; and when he had almoſt taken the place he was obliged to raiſe the ſiege, to go and meet the Ruſſian army. It is ſeated on the river Morave. E. Long. 17. 35. N. Lat. 49. 30.

OLOCENTROS, in natural hiſtory, a name given by the old Greeks to a ſmall animal of the ſpider kind, whoſe bite was accounted mortal. It is the ſame with the ſolipuga, ſo called from its ſtinging, or biting moſt violently, in places, or ſeaſons, where the ſun had the moſt power, as Africa, &c. The name *ſoliſuga* was a corrupt way of writing that word; and this ſeems alſo a falſe way of writing the word *helioccntros*, which ſignifies the ſame as ſolipuga.

OLYMPIA (Maldachini Donna), a woman of a very uncommon character. She flouriſhed about the middle of the laſt century. She was ſiſter-in-law to Pope Innocent X. and had the addreſs to acquire an unlimited power over this vain, weak, and injudicious eccleſiaſtic. Her ſon Camillo was promoted to the cardinalate, under the title of Pamphilio; but falling in love with the Princeſs Roſſana, a beautiful young widow, he laid aſide his hat, and married. The crime, if it was one, was eſteemed by the Romans in general at leaſt venial. The pope, however, was diſpleaſed; and Olympia procured their baniſhment, being afraid leſt her daughter-in-law ſhould leſſen her authority in the *ſacred court.* This authority, equally unnatural and uncommon, reflected neither honour on her who held it, nor on the man who allowed her to hold it. Such elevated ſituations, however, whether they are the reward of merit, the effect of chance, or acquired by cunning, are ſeldom very ſecure. Olympia, who had procured the diſgrace of many who did not deſerve it, and who had herſelf long merited ſuch a fate, at length experienced both diſgrace and baniſhment. This was obtained by means of Cardinal Panzirollo, a great favourite of the pope's. The immediate cauſe of it was this: The pope had determined, in order to leſſen his own trouble, to adopt a nephew, and to make him a *Cardinal Patron,* in order to give audience to ambaſſadors and miniſters, and in his abſence to preſide at the council. For this purpoſe, at the recommendation of his favourite, his holineſs made choice of Aſtalli, brother of the marquis Aſtalli, who had married a niece of Olympia. Olympia indeed was ſlightly conſulted on the affair, and ſhowed no diſapprobation of the appointment. The pope, however, no ſooner got him fixed in his new office, than he ſhowed his own weakneſs by repenting of it. Olympia too was diſpleaſed, and by her ſolicitations procured the diſgrace of Aſtalli, before he had enjoyed either the honours or emoluments of his office. Panzirollo, however, ſoon managed matters ſo as to turn the ſcales: he prevailed on the pope again to countenance and honour Aſtalli; and, what was more, had influence ſufficient to perſuade him to diſgrace Olympia, and to baniſh her the court. She had indeed abuſed her authority in a moſt ſcandalous manner, and had gained ſuch an abſolute aſcendant over the pope, that in every thing his will had been ſubſervient to her dictates.—Her avarice and ambition were unbounded: ſhe diſpoſed of all benefices, which were kept vacant till ſhe fully informed herſelf of their value: ſhe rated an office of 1000 crowns for three years, at one year's revenue, and if for life, at 12 years purchaſe, one half of which ſum ſhe required to be paid in advance: ſhe gave audience upon public affairs, enacted new laws, abrogated thoſe of former popes, and ſat in council with Innocent, with bundles of memorials in her hands. It was generally ſaid that they lived together in a criminal correſpondence, and that ſhe had charmed him by ſome ſecret incantation. In the Proteſtant countries the loves and intrigues of Innocent and Donna Olympia were repreſented upon the ſtage; and ſevere ſarcaſms were daily put into the hands of Paſquin at Rome.—As ſhe had uſurped ſuch an abſolute authority, the new cardinal nephew ſaw the neceſſity of ruining her credit; he therefore ſeconded the endeavours of Panzirollo.—He inſinuated to the pope, that his reputation had ſuffered greatly among the Catholics by her ſcandalous proceedings, and that his nuncios were treated with diſreſpect and contempt at the courts of the emperor, France, and Spain. Upon theſe repreſentations, Innocent at length, but with great reluctance, baniſhed Olympia, and was reconciled to Prince Camillo and the Princeſs Roſſana; though ſome authors affirm that her baniſhment was no more than a political retreat, and that ſhe ſtill in private directed the affairs of the pope. A woman of Olympia's character, however, with ſuch unbounded ambition, ſuch an extravagant luſt for power, and ſuch an ambitious deſire of wealth, and who had once poſſeſſed ſo great an aſcendency over ſuch a man as Innocent, was not to be ſo eaſily put off. She was baniſhed in 1650; but in 1653, ſhe again aſſumed the ſupreme direction of affairs juſt as before her diſgrace. She again accompliſhed the diſgrace of Aſtalli, and procured the promotion of Azzolini to the office of ſecretary of the briefs. In 1654, his holineſs reſigned himſelf entirely into the hands of this aſſuming woman; who, obſerving his infirmities daily increaſing, redoubled her rapacity, diſpoſing of benefices to the higheſt bidders in all parts of Italy. She was again, however, in hazard of being diſplaced by a new favourite, *viz.* the cardinal de Retz; and had not the pope's diſſolution prevented it, it would in all probability quickly have taken place. During his laſt illneſs he received nothing but from the hands of Donna Olympia, who was at great pains to prolong his life, watched continually at his bed ſide, and prevented the ambaſſadors or others from diſturbing him with diſcourſes upon buſineſs. She is ſaid, during the laſt ten days of his life, when he continued without the uſe of reaſon, to have amaſſed about half a million of crowns. She did not find the ſucceeding pope (Alexander VII.) ſo eaſy to be played upon as his weak predeceſſor: a number of memorials were ſent in againſt her, and his holineſs was well diſpoſed to attend to them: he ordered her to retire from Rome, and at the ſame time began to examine witneſſes reſpecting her conduct. She was cut off, however, before the trial was finiſhed, by the plague, which, in 1636, afflicted Rome and its neighbourhood. Her eſtate was not confiſcated as was generally expected; and the prince Pamphilio was allowed to ſucceed her. The pope only reſerved for his own relations about a million of crowns.

Olympia (anc. geog.), with the ſurname *Piſatis* (Strabo); ſo called from the territory of Piſa in Elis; deſcribed by Strabo, "as the temple of Jupiter Olympius, before which ſtands a grove of wild olive trees, in which is the ſtadium, or foot-courſe, ſo called becauſe the eighth part of a mile; and by which the Alpheus, coming down from Arcadia, runs." Olympia, however, was famous not merely for the temple of Jupiter, but alſo for a temple of Juno, 63 feet long, with columns round it of the Doric order; and a Metroum or temple of the mother of the gods, a large Doric edifice; with holy treaſuries. Theſe, and the porticoes, a gymnaſium, prytaneum, and many more buildings, chiefly in the encloſure, with the houſes of the prieſts and other inhabitants, made Olympia no inconſiderable place. The ſtadium was in the grove of wild olive trees, before the great temple; and near it was the hippodrome or courſe for the races of horſes and chariots. The Alpheus flowed by from Arcadia with a copious and very pleaſant ſtream, which was received on the coaſt by the Sicilian ſea.

The temple of Jupiter was of the Doric order, 68 feet high to the pediment, 95 wide, and 230 long; the cell encompaſſed with columns. It was erected with the country ſtone; the roof not of earth baked, but of Pentelic marble; the ſlabs diſpoſed as tiles; the way to it up a winding ſtaircaſe. The two pediments were enriched with ſculpture; and one had over the centre a ſtatue of Victory gilded; and underneath a votive buckler of gold. At each corner was a gilded vaſe. Above the columns were fixed 21 gilded bucklers, offered at the concluſion of the Achæan war by the Roman general Mummius. The gates in the two fronts were of braſs, and over them were carved the labours of Hercules. Within the cell were double colonnades, between which was the approach to the image.

The Jupiter of Olympia was accounted alone ſufficient to immortalize its maker, Phidias. It was of ivory and gold, the head crowned with olive. In the right hand was a ſtatue of Victory; in the left a flowered ſceptre, compoſed of various metals, on which was an eagle. The ſandals were of gold, as alſo the veſtment, which was curiouſly emboſſed with lilies and animals. The throne was gold inlaid with ebony and ivory, and ſtudded with jewels, intermixed with paintings and exquiſite figures in relievo. The pillars between the feet contributed to its ſupport. Before it were walls, ſerving as a fence, decorated principally with the exploits of Hercules; the portion oppoſite to the door of a blue colour. It was the office of a family deſcended from Phidias, called *phædruntæ* or *the poliſhers*, to keep the work bright and clean. The veil or curtain was cloth rich with the purple dye of Phœnicia and with Aſſyrian embroidery, an offering of King Antiochus, and was let down from above by looſening the ſtrings. The image impreſſed on the ſpectator an opinion that it was higher and wider than it meaſured. Its magnitude was ſuch, that though the temple was very large, the artiſt ſeemed to have erred in the proportions. The god, ſitting, nearly touched the ceiling with his head; ſuggeſting an idea, that if he were to riſe up, he would deſtroy the roof. A part of the pavement before it was of black marble, encloſed in a rim of Parian or white, where they poured oil to preſerve the ivory.

The altar of Jupiter Olympius was of great antiquity, and compoſed of aſhes from the thighs of the victims, which were carried up and conſumed on the top with wood of the white poplar tree. The aſhes alſo of the prytaneum, in which a perpetual fire was kept on a hearth, were removed annually on a fixed day, and ſpread on it, being firſt mingled with water from the Alpheus. The cement, it was affirmed, could be made with that fluid only; and therefore this river was much reſpected, and eſteemed the moſt friendly of any to the god. On each ſide of the altar were ſtone ſteps. Its height was 22 feet. Girls and women, when allowed to be at Olympia, were ſuffered to aſcend the baſement, which was 125 feet in circumference. The people of Elis ſacrificed daily, and private perſons as often as they choſe.

Religion flouriſhed at Olympia, and many deities were worſhipped beſides Jupiter. Pauſanias has enumerated above 60 altars of various ſhapes and kinds. One of the unknown gods ſtood by the great altar. The people of Elis offered on all theſe monthly; laying on them boughs of olive; burning incenſe, and wheat mixed with honey; and pouring libations of ſuch liquors as the ritual preſcribed. At the latter ceremony ſometimes a form of prayer was uſed, and they ſung hymns compoſed in the Doric dialect.

Olympia was ſituated on an eminence, between two mountains called *Oſſa* and *Olympus*. Though its ancient ſplendour is gone, the place reminds the traveller of of what it once was. It is in the Morea, being now a ſmall place called *Longinico*, 50 miles ſouth of Lepanto, in E. Long. 22. 0. N. Lat. 37. 40.

OLYMPIAD, the ſpace of four years, whereby the Greeks reckoned time.—The firſt Olympiad fell, according to the accurate and learned computation of ſome of the moderns, exactly 776 years before the firſt year of Chriſt, or 775 before the year of his birth, in the year of the Julian period 3938, and 22 years before the building of the city of Rome. The games were exhibited at the time of the full moon next after the ſummer ſolſtice; therefore the Olympiads were of unequal length, becauſe the time of the full moon differs 11 days every year, and for that reaſon they ſometimes began the next day after the ſolſtice, and at other times four weeks after. The computation by Olympiads ceaſed, as ſome ſuppoſe, after the 364th, in the year 440 of the Chriſtian era. It was univerſally adopted not only by the Greeks, but by many of the neighbouring countries; though ſtill the Pythian games ſerved as an epoch to the people of Delphi and to the Bœotians; the Nemæan games to the Argives and Arcadians; and the Iſthmian to the Corinthians and the inhabitants of the Peloponneſian iſthmus. To the Olympiads hiſtory is much indebted. They have ſerved to fix the time of many momentous events; and indeed before this method of computing time was obſerved, every page of hiſtory is moſtly fabulous, and filled with obſcurity and contradiction, and no true chronological account can be properly eſtabliſhed and maintained with certainty.

OLYMPIAS, a celebrated woman, who was daughter of a king of Epirus, and who married Philip king of Macedonia, by whom ſhe had Alexander the Great. Her haughtineſs, and more probably her infidelity, obliged Philip to repudiate her, and to marry Cleopatra, the niece of King Attalus. Olympias was ſenſible of this injury, and Alexander ſhowed his diſapprobation of his father's meaſures, by retiring from the court to his mother. The murder of Philip, which ſoon followed this diſgrace, and which ſome have attributed to the intrigues of Olympias, was productive of the greateſt extravagances. The queen paid the greateſt honour to her huſband's murderer. She gathered his mangled limbs, placed a crown of gold on his head, and laid his aſhes near thoſe of Philip. The adminiſtration of Alexander, who had ſucceeded his father, was in ſome inſtances offenſive to Olympias; but when the ambition of her ſon was concerned, ſhe did not ſcruple to declare publicly that Alexander was not the ſon of Philip, but that he was the offspring of an enormous ſerpent who had ſupernaturally introduced himſelf into her bed. When Alexander was dead, Olympias ſeized the government of Macedonia; and, to eſtabliſh her uſurpation, ſhe cruelly put to death Aridæus, with his wife Eurydice, as alſo Nicanor the brother of Caſſander, with 100 leading men of Macedon, who were inimical to her intereſt. Such barbarities did not long remain unpuniſhed: Caſſander beſieged her in Pydna, where ſhe had retired with the remains of her family, and ſhe was obliged to ſurrender after an obſtinate ſiege. The conqueror ordered her to be accuſed, and to be put to death. A body of 200 ſoldiers were ordered to put the bloody commands into execution, but the ſplendour and majeſty of the queen diſarmed their courage; and ſhe was at laſt maſſacred by thoſe whom ſhe had cruelly deprived of their children, about 316 years before the Chriſtian era.

OLYMPIC GAMES, were ſolemn games among the ancient Greeks, ſo called from Olympian Jupiter, to whom they were dedicated; and by ſome ſaid to be firſt inſtituted by him, after his victory over the ſons of Titan; others aſcribe their inſtitution to Hercules, not the ſon of Alcmena, but one of much greater antiquity; others to Pelops; and others to Hercules the ſon of Alcmena. By whomſoever they were inſtituted, we know that, at a period rather early, they had fallen into diſuſe. The wars which prevailed among the Greeks, for a while, totally interrupted the religious ceremonies and exhibitions with which they had been accuſtomed to honour the common gods and heroes; but the Olympic games were reſtored on the following occaſion. Amidſt the calamities which afflicted or threatened Peloponneſus, Iphitus, a deſcendant of Oxylus, to whom the province of Eleia * had fallen in the general partition of the peninſula, applied to the Delphic oracle. The prieſts of Apollo, ever diſpoſed to favour the views of kings and legiſlators, anſwered agreeably to his wiſh, that the feſtivals anciently celebrated at Olympia, on the Alpheus, muſt be renewed, and an armiſtice proclaimed for all the ſtates willing to partake of them, and deſirous to avert the vengeance of heaven. Fortified by this authority, and aſſiſted by the advice of Lycurgus, Iphitus took meaſures, not only for reſtoring the Olympic ſolemnity, but for rendering it perpetual. The injunction of the oracle was ſpeedily diffuſed through the remoteſt parts of Greece by the numerous votaries who frequented the ſacred ſhrine. The armiſtice was proclaimed in Peloponneſus, and preparations were made in Eleia for exhibiting ſhows and performing ſacrifices. In the heroic ages, feats of bodily ſtrength and addreſs were deſtined to the honour of deceaſed warriors; hymns and ſacrifices were reſerved for the gods: but the flexible texture of Grecian ſuperſtition, eaſily confounding the expreſſions of reſpectful gratitude and pious veneration, enabled Iphitus to unite both in his new inſtitution.

The feſtival, which laſted five days, began and ended with a ſacrifice to Olympian Jove. The intermediate time was chiefly filled up by the gymnaſtic exerciſes, in which all freemen of Grecian extraction were invited to contend, provided they had been born in lawful wedlock, and had lived untainted by any infamous immoral ſtain. The preparation for this part of the entertainment was made in the gymnaſium of Elis, a ſpacious edifice, ſurrounded by a double range of pillars, with an open area in the middle. Adjoining were various apartments, containing baths, and other conveniences for the combatants. The neighbouring country was gradually adorned with porticoes, ſhady walks and groves, interſperſed with ſeats and benches; the whole originally deſtined to relieve the fatigues and anxiety of the candidates for Olympic fame; and frequented in later times, by ſophiſts and philoſophers, who were fond to contemplate wiſdom, and communicate knowledge, in thoſe delightful retreats. The order of the athletic exerciſes, or combats, was eſtabliſhed by Lycurgus, and correſponded almoſt exactly to that deſcribed by Homer, in the 23d book of the Iliad, and eighth of the Odyſſey. Iphitus, we are told, appointed the other ceremonies and entertainments; ſettled the regular return of the feſtival at the end of every fourth year, in the month of July; and gave to the whole ſolemnity that form and arrangement, which it preſerved with little variation above a thouſand years; a period exceeding the duration of the moſt famous kingdoms and republics of antiquity. Among the benefactors of Olympia, at a much later period, was reckoned Herod, who was afterwards king of Judæa. Seeing, on his way to Rome, the games neglected or dwindling into inſignificance from the poverty of the Eleans, he diſplayed vaſt munificence as preſident, and provided an ample revenue for their future ſupport and dignity.

The care and management of the Olympics belonged for the moſt part to the Eleans; who on that account enjoyed their poſſeſſions without moleſtation, or fear of war or violence. They appointed a certain number of judges, who were to take care that thoſe who offered themſelves as competitors ſhould perform their preparatory exerciſes; and theſe judges, during the ſolemnity, ſat naked, having before them a crown of victory, formed of wild olive, which was preſented to whomſoever they adjudged it. Thoſe who were conquerors were called *Olympionices*, and were loaded with honours by their countrymen. At theſe games women were not allowed to be preſent; and if any woman was found, during the ſolemnity, to have paſſed the river Alpheus, ſhe was to be thrown headlong from a rock. This, however, was ſometimes neglected; for we find not only women preſent at the celebration, but alſo ſome among the combatants, and ſome rewarded with the crown. The preparations for theſe feſtivals were great. No perſon was permitted to enter the liſts, if he had not regularly exerciſed himſelf ten months before the celebration at the public gymnaſium of Elis. No unfair dealings were allowed; whoever attempted to bribe his adverſary was ſubjected to a ſevere fine; and even the father and relations were obliged to ſwear that they would have recourſe to no artifice which might decide the victory in favour of their friends. No criminals, nor ſuch as were connected with impious and guilty perſons, were ſuffered to preſent themſelves as combatants. The wreſtlers were appointed by lot. Some little balls ſuperſcribed with a letter were thrown into a ſilver urn, and ſuch as drew the ſame letter were obliged to contend one with the other. He who had an odd letter remained the laſt; and he often had the advantage, as he was to encounter the laſt who had obtained the ſuperiority over his adverſary. In theſe games were exhibited running, leaping, wreſtling, boxing, and the throwing of the quoit, which was called altogether *πενταθλον*, or *quinquertium*. Beſides theſe, there were horſe and chariot races, and alſo contentions in poetry, eloquence, and the fine arts. The only reward that the conqueror obtained was a crown of olive. This, as ſome ſuppoſe, was in memory of the labours of Hercules, which were accompliſhed for the univerſal good of mankind, and for which the hero claimed no other reward but the conſciouſneſs of having been the friend of mankind. So ſmall and trifling a reward ſtimulated courage and virtue, and was the ſource of greater

* *Gillies Hiſtory of Greece.*

greater honours than the moſt unbounded treaſures. The ſtatues of the conquerors, called *Olympionicæ*, were erected at Olympia in the ſacred wood of Jupiter.

Their return home was that of a warlike conqueror; they were drawn in a chariot by four horſes, and everywhere received with the greateſt acclamations. Their entrance into their native city was not through the gates; to make it more grand and more ſolemn, a breach was made in the walls. Painters and poets were employed in celebrating their names; and indeed the victories ſeverally obtained at Olympia are the ſubjects of the moſt beautiful odes of Pindar. The combatants were naked. A ſcarf was originally tied round their waiſt; but when it had entangled one of the adverſaries, and been the cauſe that he loſt the victory, it was laid aſide, and no regard was paid to decency. The Olympic games were obſerved every fifth year, or, to ſpeak with greater exactneſs, after a revolution of four years, and in the firſt month of the fifth year, and they continued for five ſucceſſive days. As they were the moſt ancient and moſt ſolemn of all the feſtivals of the Greeks, it will not appear wonderful, that they drew ſo many people, not only inhabitants of Greece, but of the neighbouring iſlands and countries.

Such is the account of Grecian writers, who have, doubtleſs, often aſcribed to poſitive inſtitution many inventions and uſages naturally reſulting from the progreſſive manners of ſociety. When we come to examine the Elean games in their more improved ſtate, together with the innumerable imitations of them in other provinces of Greece, there will occur reaſons for believing, that many regulations, referred by an eaſy ſolution to the legiſlative wiſdom of Iphitus or Lycurgus, were introduced by time or accident, continued through cuſtom, improved by repeated trials, and confirmed by a ſenſe of their utility †. Yet ſuch an inſtitution as the Olympiad, even in its leaſt perfect form, muſt have been attended with manifeſt advantages to ſociety. It is ſufficient barely to mention the ſuſpenſion of hoſtilities which took place, not only during the celebration of the feſtival, but a conſiderable time both before and after it. Conſidered as a religious ceremony, at which the whole Grecian name was invited, and even enjoined, to aſſiſt, it was well adapted to facilitate intercourſe, to promote knowledge, to ſoften prejudice, and to haſten the progreſs of civilization and humanity. Greece, and particularly Peloponneſus, was the centre from which the adventurous ſpirit of its inhabitants had diffuſed innumerable colonies through the ſurrounding nations. To theſe widely ſeparated communities, which, notwithſtanding their common origin, ſeemed to have loſt all connexion and correſpondence, the Olympiad ſerved as a common bond of alliance and point of re-union. The celebrity of this feſtival continually attracted to it the characters moſt diſtinguiſhed for genius and enterpriſe, whoſe fame would have otherwiſe been unknown and loſt in the boundleſs extent of Grecian territory. The remote inhabitants, not only of European Greece, but of Aſia and Africa, being aſſembled to the worſhip of common gods, were formed to the ſenſe of a general intereſt, and excited to the purſuit of national honour and proſperity. Strangers of ſimilar diſpoſitions might confirm in Elis the ſacred and indiſſoluble ties of hoſpitality. If their communities were endangered by any barbarous power, they might here ſolicit aſſiſtance from their Grecian brethren. On other occaſions they might explain the benefits which, in peace or war, their reſpective countries were beſt qualified to communicate. And the Olympic feſtival might thus ſerve the purpoſe of reſident ambaſſadors, and other inſtitutions alike unknown to antiquity.

OLYMPUS, the name of ſeveral mountains.—One bounding Bithynia on the ſouth.—Another in the iſland of Cyprus, on whoſe top was a temple of Venus, which women were not permitted either to enter or to ſee (Strabo.)—A third, Olympus of Galatia (Livy). —A fourth, of Lycia, with a noble cognominal town, near the ſea coaſt (Strabo, Cicero), extinct in Pliny's time, there remaining only a citadel: the town was deſtroyed by P. Servilius Iſauricus (Florus), having been the retreat of pirates. From this mountain there was an extenſive proſpect of Lycia, Pamphilia, and Piſidia (Strabo).—A fifth, Olympus of Myſia (Ptolemy); thence ſurnamed *Olympena*, anciently *Minor*; one of the higheſt mountains, and ſurnamed *Myſius* (Theophraſtus;) ſituated on the Propontis, and thence extending more inland.—A ſixth, on the north of Theſſaly, or on the confines of Macedonia; famous for the fable of the giants (Virgil, Horace, Seneca); reckoned the higheſt in the whole world, and to exceed the flight of birds (Apuleius), which is the reaſon of its being called *heaven*, than which nothing is higher: the ſerenity and calmneſs which reign there are celebrated by Homer, Lucan, and Claudian.

OLYRA, in botany: A genus of the triandria order, belonging to the monœcia claſs of plants; and in the natural method ranking under the 4th order, *Gramina*. The male calyx is a biflorous and ariſtated glume; the corolla a beardleſs glume; the female calyx is an uniflorous, patulous, and ovate glume; the ſtyle is bifid, and the ſeed cartilaginous.

OMAR (Ebn Al Khattab) ſucceſſor of Abu Becr. —The Mohammedan impoſture, like every other falſehood of its kind, copies after the truth as far as was thought convenient or proper; and miracles being the grand proof of revelation, it was to be expected that all pretences to that ſhould aſſume at leaſt the appearances of them. Few ſyſtems of faith are more abſurd than Mohammed's; yet, though he diſclaimed miracles, it was ſupported, as we are told by latter writers, by a variety of them, which, however, unfortunately for the creed they were contrived to ſupport, are too trifling, abſurd, and contradictory, to deſerve the ſmalleſt attention.

They tell us, but upon grounds too vague and indeterminate to command belief, that Omar was miraculouſly converted to this faith: a man he is reported to have been, before this event, truly reſpectable, and in particularly a violent oppoſer of the Arabian prophet. Mohammed, it ſeems, felt this oppoſition, and regretted it; he therefore, with the fervour, and, as it happened, with the ſucceſs of a true prophet, according to his followers account, prayed for the converſion of this his dangerous antagoniſt. Omar, it is ſaid, had no ſooner read the 20th chapter of the Koran than he was convinced: upon which he inſtantly repaired to Mohammed and his followers, and declared his converſion. It is ſaid, that at one time he intended to murder

† Gillies's Hiſtory of Greece.

murder the prophet; and various cauſes are aſſigned for the prevention of this ſhocking piece of ſacrilege. After his wonderful converſion, the Mohammedan writers inform us that he was ſurnamed *Al Faruk*, or the "divider;" becauſe, ſay they, when a certain Moſlem was condemned by Mohammed for his iniquitous treatment of a Jew, and appealed afterwards from the ſentence of the prophet to Omar, he cut him in two with his ſcimitar, for not acquieſcing in the deciſion of ſo upright a judge: which circumſtance when Mohammed heard, he gave him the ſurname of *Al Faruk*, or "the divider;" becauſe, by this action, he had ſhown himſelf capable of perfectly diſtinguiſhing between truth and falſehood. Al Kodai affirms, that 39 of Omar's adherents followed his example the ſame day he profeſſed himſelf a votary of Mohammed. The converſion of Hamza and Omar Ebn Al Khattab happened in the year preceding the firſt flight of the Moſlems into Ethiopia, or the fourth year of Mohammed's miſſion, according to Abulfeda. He was unqueſtionably a great acquiſition to the prophet, and enabled him to carry on his ſchemes to far more purpoſe than he could poſſibly have done without him, or if he had continued his enemy. Omar at length found his ſervices in the cauſe he had undertaken ſufficiently honoured and amply rewarded; for on the death of Abu Beer, who had ſucceeded the Impoſtor himſelf, he was promoted to the regal and pontifical dignity. The title firſt aſſigned him was the *caliph of the caliph of the apoſtle of God;* or in other words *the ſucceſſor of the ſucceſſor of Mohammed:* but the Arabs conſidering that this title, by the addition to be annexed to it at the acceſſion of every future caliph, would be too long, they, by univerſal conſent, ſaluted him *the emperor of the believers;* which illuſtrious title, at this juncture conferred on Omar, deſcended afterwards to all the ſucceſſors of that prince. Our readers will not expect us to follow the caliph with minute exactneſs through the tranſactions of his reign. This would indeed ſwell our article beyond all proportion. We ſhall therefore confine ourſelves to ſome of the leading facts.

His arms appear to have been particularly ſucceſsful; the Perſians he conquered, and Jeruſalem ſubmitted to his power; nor does he appear to have been checked in a ſingle inſtance. In conſequence, however, of his ſucceſs, an attempt was made to aſſaſſinate him. The fact is thus related: Wathek Ebn Moſafer, a reſolute young Arab, was procured by the king of Ghaſſan, and ſent to Medina for this very purpoſe. Some time after his arrival, obſerving Omar to fall aſleep under a tree on which he had placed himſelf, ſo as not to be diſcovered by any perſon, he drew his dagger, and was upon the point of ſtabbing him, when, lifting up his eyes, he ſaw a lion walking round about him, and licking his feet. Nor did the lion ceaſe to guard the caliph till he awoke; but then inſtantly went away. This phenomenon ſtruck Wathek with a profound reverence for Omar, whom he now revered as the peculiar care of heaven. He therefore came down from the tree, on which the lion had forced him to remain, kiſſed the caliph's hand, confeſſed his crime, and embraced the Mohammedan religion; being ſo ſtrongly affected with the wonderful deliverance he had been an eye witneſs of. His life, however, was at length ended by aſſaſſination; for about two years after the concluſion of the Nohawandian war, in which the Arabs probably ſtill farther extended their conqueſts, though no account of their military operations during that period has reached us, that is, in the 23d year of the Hegira, according to Abu Jaafar Al Tabari, the caliph Omar Ebn Al Khattab was aſſaſſinated by a Perſian ſlave; of which horrid fact the Arab writers have handed down the following particulars: Abu Lulua, a Perſian of the Magian ſect, whoſe name was *Firuz*, one of Al Mogheira Ebn Al Shaabah's ſlaves, was obliged by his maſter to pay daily two dirhems, in conformity to the Mohammedan cuſtom, for the free exerciſe of this religion. Firuz reſenting this treatment, complained of it to the caliph, and deſired that ſome part at leaſt of the tribute exacted of him might be remitted; but this favour being refuſed by Omar, the Perſian threatened his deſtruction; which he ſoon after effected, by ſtabbing him thrice in the belly with a dagger, while he was in the moſque at Medina performing his morning devotions. The Arabs then preſent perceiving that the villain had imbrued his hands in the blood of their ſovereign, immediately ruſhed upon him; but he made ſo deſperate a defence, that he wounded 13 of the aſſailants, and ſeven of them mortally. At laſt one of the caliph's attendants threw his veſt over him, and ſeized him; upon which he ſtabbed himſelf and ſoon after expired. According to Theophanes, this Firuz was an apoſtate or renegade, and conſequently had before embraced the Mohammedan religion: but this aſſertion is by no means probable; becauſe on his becoming a convert to Iſlamiſm, he muſt have been manumitted by his maſter, and on his relapſing into Magiſm, he would have been put to death by the caliph's order: neither of which particulars are conſiſtent with what we find related by the Arab hiſtorians, and even by our Greek chronographer himſelf. Omar languiſhed three days and then died, in the month of Dhu'lhajja, and the 23d year of the Hegira, which began in the year of our Lord 643. Authors are not agreed with regard to the duration of his caliphate. The Arab hiſtorians, whom we are inclined to follow, ſay that he reigned between 10 and 11 years. Theophanes affirms, that he was murdered in the 12th year of his caliphate, and Dionyſius Telmarenſis extends the length of his reign to 12 complete years. Only one of the wounds given him by Firuz was mortal, and that he received under his navel. At his death he was 63 years old; which, as we are told by an Arab author, was the age of Mohammed himſelf, Abu Beer, and Ayeſha, one of the prophet's wives, when they died. When Omar fell in the moſque, Abd'alrahman Ebn Awf, one of Mohammed's firſt converts, ſupplied his place during the remainder of the ſervice; and three days before his death, Sahib Ebn Tarſib, at his command, officiated for him. His body was interred in Ayeſha's apartment, near that of the prophet Mohammed. We are informed by Eutychius, that during his caliphate he performed the pilgrimage to Mecca nine times. His extenſive conqueſts made the Moſlem empire one of the moſt powerful and formidable monarchies in the world. His diſpoſition is repreſented to us, with evident partiality indeed, as one of the beſt poſſible, and his temperance has always been highly extolled.

OMBI, a city of ancient Egypt, afterwards called *Arſinoe* and *Crocodilopolis*, was the capital of one of the nomes into which that country was divided, and is remarkable, in the annals of idolatry, for the hatred of its inhabitants to the religion of their neighbours the citizens of Tentyra.

The genius of paganiſm was ſo complying with reſpect to the objects of religious worſhip, that although each nation, each city, and almoſt every family, had its own tutelar god, we know not a ſingle inſtance, out of Egypt, of one tribe of Pagans perſecuting another for worſhipping gods different from theirs. The Jews and Chriſtians were indeed perſecuted by the Romans, not however for worſhipping the true God, but becauſe, together with him, they would not worſhip Jupiter, Juno, and all the rabble of heathen divinities.

The reaſon of the almoſt univerſal tolerance of idolaters to one another, and of the intolerance of all to the Jews and Chriſtians, is very obvious. Not a ſingle Pagan, a very few philoſophers perhaps excepted, ever thought of paying his adoration to the Supreme and ſelf-exiſtent Being, but to inferior divinities, to whom it was ſuppoſed that the care of particular perſons, families, cities, and nations was conſigned by the God of the univerſe. The conſequence was, that, as no perſon denied the divinity of his neighbour's object of worſhip, an intercommunity of gods was everywhere admitted, and all joined occaſionally in adoring the gods of the various nations. By the Jews and Chriſtians this communion was rejected as in the higheſt degree impious; and it could not well be maintained between the citizens of Ombi and thoſe of Tentyra.

That brutes were worſhipped in Egypt is univerſally known (See POLYTHEISM); and Diodorus the Sicilian informs us, in a paſſage quoted by Euſebius *, that "the cities and nomes of Egypt being at one time prone to rebellion, and to enter into conſpiracies againſt monarchical government, one of their moſt politic kings contrived to introduce into the neighbouring nomes the worſhip of different animals; ſo that while each reverenced the deity which itſelf held ſacred, and deſpiſed that which its neighbours had conſecrated, they could hardly be brought to join cordially in one common deſign to the diſturbance of the government."

In this diſtribution of gods he conferred upon Ombi the *crocodile*, and upon Tentyra the mortal enemy of that monſter, the *ichneumon*. The conſequence of which was, that while the Ombites worſhipped the crocodile, the Tentyrites took every opportunity of ſlaughtering him, inſomuch that, according to Strabo, the very voice of an inhabitant of Tentyra put the crocodile to flight. This, we confeſs, is a very improbable fact; but it is certain that the mutual hatred of thoſe cities, on account of their hoſtile gods, roſe to ſuch a height, that whenever the inhabitants of the one were engaged in the more ſolemn rites of their religion, thoſe of the other were ſure to embrace the opportunity of ſetting fire to their houſes, and rendering them every injury in their power to inflict. And what may, to a ſuperficial thinker, appear extraordinary, though it will excite no wonder in the breaſt of him who has ſtudied mankind, this animoſity continued between the inhabitants of the two cities long after the crocodile and ichneumon had loſt their divinity.

The conduct of the Egyptian monarch was admirably calculated for preventing the nation from combining againſt the government; and it extended its influence over the whole kingdom. Diodorus informs us, that he aſſigned to each nome an animal to worſhip, which was hated, killed, and ſometimes fed upon by the inhabitants of the neighbouring nome; and we know upon higher authority than his, that the Iſraelites could not offer ſacrifices in Egypt, becauſe the bullock was deemed ſacred over the whole country.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five perſons, but generally by three. When three play at this game, nine cards are dealt to each party; the whole ombre pack being only 40; becauſe the eights, nines, and tens, are thrown out of the pack. There are two ſorts of counters for ſtakes, the greater and the leſſer; the laſt having the ſame proportion to the other as a penny to a ſhilling: of the greater counters each man ſtakes one for the game; and one of the leſſer for paſſing for the hand, when eldeſt, and for every card taken in. As to the order and value of the cards, the ace of ſpades, called *ſpadillo*, is always the higheſt trump, in whatſoever ſuit the trump be; the *manille*, or black duce, is the ſecond; and the *baſto*, or ace of clubs, is always the third: the next in order is the king, the queen, the knave, the ſeven, the ſix, the five, four, and three. Of the black there are 11 trumps; of the red, 12. The leaſt ſmall cards of the red are always the beſt, and the moſt of the black; except the duce and red ſeven, both of which are called the *manilles*, and are always ſecond when the red is a trump. The red ace, when a trump, enters into the fourth place, and is called *punto*, otherwiſe it is only called an ace. The three principal cards are called *matadores*; which have this privilege, that they are not obliged to attend an inferior trump when it leads; but for want of a ſmall trump, the perſon may renounce trumps, and play any other card; and when theſe are all in the ſame hand, the others pay three of the greater counters a-piece; and with theſe three for a foundation, he may count as many matadores as he has cards in an uninterrupted ſeries of trumps; for all which the others are to pay one counter a-piece. He who hath the firſt hand is called *ombre*, and has his choice of playing the game, of naming the trump, and of taking in as many and as few cards as he pleaſes; and after him the ſecond, &c. But if he does not name the trump before he looks on the cards he has taken in, any other may prevent him, by naming what trump he pleaſes. He that has the firſt hand ſhould neither take in, nor play, unleſs he has at leaſt three ſure tricks in his hand: for, as he wins the game who wins moſt tricks, he that can win five of the nine has a ſure game; which is alſo the caſe if he wins four, and can ſo divide the tricks as that one perſon may win two, and the other three.

If a perſon plays without diſcarding or changing any cards, this is called *playing ſans prendre*; and if another wins more tricks than he, he is ſaid to *win codille*. The over-ſights in the courſe of the game are called which tranſlation [illegible] mly juſt. But how the Aſſyrians could export [illegible] ry from the iſles of Kittim, and faſhion it into [illegible] ches for the Tyrian mariners, is, in my opinion, [illegible] oblem of no eaſy ſolution. The fact is, Aſhurim [illegible] uld be Aſherim, that is, the company of the m[illegible] f Aſher. The tribe of Aſher obtained its inh[illegible] ince in the neighbourhood of Tyre; (ſee Joſh. xi[illegible] 28.) ‘And Hebron, and R[illegible] b, and Hammon [illegible] Canah, unto Zidon the great.’ The companies [illegible] the tribe of the Aſherites then, and not the Aſh[illegible], were the people who manufactured the benche[illegible] queſtion.

---

* Prep. Evang. p. 32. Steph. ed.

“ [illegible] that as it may, the ivory of which theſe implemen[illegible] were formed was imported from the iſles of [illegible] im, that is, from Greece and its neighbourhood. [illegible] e iſlands, it is certain, never produced ivory. [illegible] hey muſt therefore have imported it from ſome other country; but no other country, to which the Greeks and their neighbours could have extended their commerce, except the north of Africa, produced that commodity. The concluſion then is, that the maritime ſtates of Aſia Minor, Greece, and probably the Hetruſcans on the weſt coaſt of Italy, carried on a gainful commerce with Spain and Barbary at a very early period.

“ We have now ſeen that the original Tarſhiſh on the coaſt of Aſia Minor did not produce the metals imported by Solomon’s fleet; that no Tarſhiſh is to be found in the eaſtern parts of the globe; that the Tarſhiſh we are in queſt of was undoubtedly ſituated ſomewhere towards the weſt of Judea: we have ſhown that the mercantile people of Aſia Minor, Greece, and probably of Italy, actually imported ſome of thoſe articles from the coaſt of Africa; we have hazarded a conjecture, that Spain was the modern Tarſhiſh, and that very country from which Solomon imported his ſilver, and the Tyrians their ſilver, iron, tin, and lead. Let us now make a trial whether we cannot exhibit ſome internal proofs in ſupport of the hypotheſis we have above adopted.

“ The ancients divided Spain into three parts, Bætica, Luſitania, and Tarraconenſis. Bætica is the modern Andaluſia. It ſtretched along the Fretum Herculeum, or Straits of Gibraltar, to the mouth of the Guadalquiver. This region is thought by ſome to have been the Elyſian Fields of the poets. The river Bætis, which divides it, is called *Tarteſſus* by Ariſtotle, Steſichorus, Strabo, Pauſanias, Steph. Byzant. and Avianus. Here too we have a city and a lake of the ſame name. But Tarteſſus is poſitively the very ſame with Tarſhiſh. The Phœnicians, by changing *ſchin* into *thau*, made it Tartiſh. The Greeks manufactured the reſt, by changing Tartiſh into Tartis, and in proceſs of time into ταρτησσος. That the Phœnicians actually changed *ſchin* into *thau* is certain; for Plutarch tells us in the life of Sylla, that in their language an ox was called *thor*, which is, no doubt, the ſame with the Hebrew *ſhor*.

10 arſhiſh paniſh Bæ-

“ From this deduction, it appears highly probable at leaſt, that the Spaniſh Bætica was originally called *Tarſhiſh*. Indeed this ſimilarity of names has operated ſo powerfully on the learned Bochart, and on ſome other moderns of no mean figure, that they have poſitively affirmed, as Joſephus had done before them, that the patriarch Tarſhiſh actually ſettled in that country. This I ſhould think not altogether probable; but that his deſcendants who ſettled on the coaſt of Aſia Minor colonized Bætica, and carried on an uninterrupted commerce to that country, along with the Phœnicians, for many centuries after it was peopled, and that from the circumſtances above narrated, it was denominated *Tarſhiſh*, are facts too palpable to admit of contradiction.

“ Let us now ſee whether this Bætica, where I have endeavoured to fix the ſituation of the Tarſhiſh of the Scriptures, was actually furniſhed with thoſe articles of commerce which are ſaid to have been imported from that country. To enlarge on this topic would be altogether ſuperfluous. Diodorus Siculus, Strabo, Polybius, Pliny, Solinus, and, in one word, all the Greek and Roman hiſtorians who have mentioned that region, have unanimouſly exhibited it as the native land of ſilver, iron, and tin: to theſe, contrary to the opinions of the celebrated modern traveller, they likewiſe add gold in very large quantities.”

Our author having thus aſcertained the ſituation of Tarſhiſh, proceeds to prove, by a maſs of evidence too large for our inſertion, that the Edomites and Tyrians had doubled the Cape, and almoſt encompaſſed Africa, long before the era of Solomon. Then referring to 1 Kings, chap. ix. and x. 2 Chron. viii. ix. 2 Kings xxii. and 2 Chron. xx. he obſerves, that from theſe authorities it appears indubitable, that the fleets of Solomon and Hiram ſailed from Eloth and Ezion-geber; that the voyages to Ophir and Tarſhiſh were exactly the ſame, performed at one and the ſame time, by the very ſame fleet; which muſt neceſſarily have encompaſſed the peninſula of Africa before it could arrive at the country of Tarſhiſh. This being the caſe, the traders might eaſily enough collect the gold on the coaſt of Guinea, or on what is now vulgarly called the *Gold Coaſt*. The ivory they might readily enough procure on the Barbary coaſt, oppoſite to Tarſhiſh. In Africa, too, they might hunt apes, monkies, baboons, &c.; and peacocks, or rather parrots, and parroquets, they might ſurpriſe in the foreſts which abounded on the coaſt. In Spain, ſilver, iron, lead, and tin, were, one may ſay, the native produce of the ſoil. Even at this early period, the Phœnician navigators had diſcovered the Caſſiterides, or Scilly iſlands and Cornwall; and from that region, in company with the merchants, may have ſupplied them with that rare commodity.

“ I have ſuppoſed that the navy of Solomon and Hiram collected their gold in the courſe of their voyage ſomewhere on the coaſt of Africa, beyond the Cape, for the following reaſons: Had they found the golden fleece at Sofala (A), or any part of the coaſt of Africa, they would have choſen to return and unlade at Eloth or Ezion-geber, rather than purſue a long and dangerous courſe, quite round Africa, to Tarſhiſh; to which laſt country they might have ſhaped their

---

(A) That Sofala oppoſite to the iſland of Madagaſcar was Ophir, was an ancient conjecture. See Bochart, Chan. L. II. Cap. 27. p. 160. 4to.

courſe much more commonly from Zidon, Tyre, Joppa, &c. But being obliged to double the Cape in queſt of ſome of theſe articles which they were enjoined to import, they puſhed onward to Tarſhiſh, and returned by the Pillars of Hercules to Tyre, or perhaps to Joppa, &c. Their next voyage commenced from one or other of theſe ports, from which they directed their courſe to Tarſhiſh; and having taken in part of their lading there, they afterwards coaſted round Africa, and ſo arrived once more at Eloth or Ezion-geber.

"Let us now attend to the ſpace of time in which theſe voyages were performed. We are told expreſsly (2 Chron. ix. 21.) that once every three years came the ſhips of Tarſhiſh, &c. This is exactly the time one would naturally imagine neceſſary to perform ſuch a diſtant voyage, at a period when navigation was ſtill in its infancy, and mariners ſeldom adventured to loſe ſight of the coaſt. Of this we have an irrefragable proof in the hiſtory of a voyage round the very ſame continent, undertaken and accompliſhed in the very ſame ſpace of time, about two centuries after.

"We learn from Herodotus, L. II. cap. 149. that [illegible] of the latter kings of Egypt, whom the Scripture calls *Pharaoh Necho*, built a great number of ſhips, both on the Red ſea and the Mediterranean. The ſame hiſtorian, Lib. IV. cap. 42. informs us, that this enterpriſing monarch projected a voyage round the the continent of Africa, which was actually accompliſhed in the ſpace of three years. In the conduct of this enterpriſe, he employed Phœnician mariners, as Solomon had done before him. Theſe, we may ſuppoſe, were aſſiſted in the courſe of this navigation by charts or journals, or at leaſt by traditional accounts derived from their anceſtors: 'Theſe navigators (ſays the hiſtorian) took their departure from a port on the Red ſea, and ſailing from thence into the ſouthern ocean, and, in the beginning of autumn, landing on the coaſt of Africa, there they ſowed ſome grain which they had carried out with them on board their veſſels. In this place they waited till the crop was ripened; and, having cut it down, they proceeded on their voyage, Having ſpent two years in this navigation, in the third they returned to Egypt, by the Pillars of Hercules. Theſe mariners, adds the author, reported a fact, which, for [illegible] part, he could by no means believe to be true, namely, that in one part of their courſe their ſhadows fell on their right; a circumſtance which gives conſiderable weight to the truth of the relation.

"Let it now be obſerved, that Phœnician mariners navigated the fleet of Solomon: the ſame people conducted that of Necho: the fleet of Necho ſpent three years in the courſe of its voyage; that of Solomon did the ſame in its courſe about two centuries before: the fleet of Necho ſailed from a port on the Red ſea; that of Solomon took its departure from Eloth or Ezion-geber, ſituated on the ſame ſea: the fleet of the former returned by the Pillars of Hercules; that of the latter, according to the hypotheſis, purſued the very ſame route. Such a coincidence of ſimilar circumſtances united with thoſe adduced in the preceding part of this article, ſeem to prove almoſt to a demonſtration, that the navy of Hiram and Solomon performed a voyage round Africa, in that age, in the ſame manner as that of Necho did two centuries after.

"Upon the whole, I conclude, that the original Ophir, which is really Aufir or Aufr, was ſituated on the ſouth of Arabia Felix, between Saba and Havilah, which laſt was encompaſſed by one of the branches of the river of Paradiſe: that the name Ophir, i. e. Aufr, was, in conſequence of its reſemblance, in proceſs of time transferred to a region on the coaſt of Africa; and that from it firſt *Afer* and then Africa was denominated: that the primitive Tarſhiſh was Cilicia, and that the Jews applied this name to all the commercial ſtates on the coaſt of Aſia Minor, and perhaps of Italy, there being ſtrong preſumptions that the Tyrrhenians were coloniſts from Tarſhiſh; that Bætica, and perhaps ſome other regions of Spain, being planted with colonies from Tarſhiſh, likewiſe acquired the name of Tarſhiſh; that the Tyrians were ſtrictly connected with the merchants of Tarſhiſh in their commercial enterpriſes; that Tarſhiſh was certainly ſituated weſtward from Judea, Phœnicia, &c.; that no other country in the weſtern quarters produced the commodities imported by the two kings, except Spain and the oppoſite coaſts; that this country, in thoſe ages, produced not only ſilver, iron, tin, and lead, but likewiſe gold in great abundance; that the merchants of Kittim imported ivory, of which the Aſherites made benches for the Tyrians; which commodity they muſt have purchaſed on the coaſt of Barbary, where the Jews and Phœnicians would find the ſame article; that Tarſhiſh being ſituated in Spain, it was impoſſible for a fleet ſailing from Eloth or Ezion-geber, to arrive at that country without encompaſſing Africa; that, of courſe, the fleet in queſtion did actually encompaſs that continent; that the Ophir of Solomon muſt have been ſituated ſomewhere on the coaſt of Africa, to the weſt of the Cape, becauſe from it the courſe to Tarſhiſh was more eligible than to return the ſame way back to Ezion-geber."

11 Ophir ſituated on the coaſt of Africa, weſt of the Cape.

Our author ſupports this concluſion by many other arguments and authorities, which the limits preſcribed us will not permit us to detail; but perhaps the article might be deemed incomplete if we did not ſhow how he obviates an objection that will readily occur to his theory. "If the original Ophir was ſeated on the coaſt of Arabia Felix, and the modern region of the ſame name on the weſt coaſt of Africa, it may be made a queſtion, how the latter country came to be denominated from the former? Nothing (ſays our author) can be more eaſy than to anſwer this queſtion. The practice of adapting the name of an ancient country to a newly diſcovered one, reſembling the other in appearance, in ſituation, in figure, in diſtance, in the nature of the climate, productions, &c. has ever been ſo common, that to produce inſtances would be altogether ſuperfluous. The newly diſcovered region on the coaſt of Africa abounded with the ſame ſpecies of commodities by which the original one was diſtinguiſhed; and of courſe, the name of the latter was annexed to the former."

12 An objection anſwered.

Whether Mr Bruce's hypotheſis, or Dr Doig's, reſpecting the long diſputed ſituation of Solomon's *Ophir*, be the true one, it is not for us to decide. Both are plauſible, both are ſupported with much ingenuity and uncommon erudition; but we do not think that the arguments of either writer furniſh a complete confutation of thoſe adduced by the other. *Sub judice lis eſt.*

OPHIRA, in botany. A genus of the monogynia order, belonging to the octandria claſs of plants. The involucrum is bivalve and triflorous; the corolla tetrapetalous above; the berry unilocular.

OPHITES, in natural hiſtory, a ſort of variegated marble, of a duſky green ground, ſprinkled with ſpots of a lighter green, otherwiſe called *ſerpentine.* See the article MARBLE.

OPHITES, in church hiſtory, Chriſtian heretics, ſo called both from the veneration they had for the ſerpent that tempted Eve, and the worſhip they paid to a real ſerpent: they pretended that the ſerpent was Jeſus Chriſt, and that he taught men the knowledge of good and evil. They diſtinguiſhed between *Jeſus* and *Chriſt:* Jeſus, they ſaid, was born of the Virgin, but Chriſt came down from heaven to be united with him; Jeſus was crucified, but Chriſt had left him to return to heaven. They diſtinguiſhed the God of the Jews, whom they termed *Jaldabaoth*, from the ſupreme God: to the former they aſcribed the body, to the latter the ſoul of men. They had a live ſerpent, which they kept in a kind of cage; at certain times they opened the cage door, and called the ſerpent: the animal came out, and mounting upon the table, twined itſelf about ſome loaves of bread; this bread they broke and diſtributed it to the company, who all kiſſed the ſerpent: this they called their *Euchariſt.*

OPHRYS, TWYBLADE: A genus of the diandria order, belonging to the gynandria claſs of plants; and in the natural method ranking under the 7th order, *Orchideæ.* The nectarium is a little carinated below. The ſpecies are numerous; but the moſt remarkable are the following:

1. The *ovata, oval-leaved ophrys,* or *common twyblade*, hath a bulbous, fibrated root; crowned by two oval, broad, obtuſe, veined, oppoſite leaves; an erect, ſucculent, green ſtalk, ſix or eight inches high, naked above, and terminated by a looſe ſpike of greeniſh flowers, having the lip of the nectarium bifid. The flowers of this ſpecies reſemble the figure of gnats.

2. The *ſpiralis, ſpiral orchis*, or *triple ladies treſſes*, hath bulbous, oblong, aggregated roots; crowned by a cluſter of oval, pointed, ribbed leaves; erect ſimple ſtalks, half a foot high; terminated by long ſpikes of white odoriferous flowers, hanging to one ſide, having the lip of the nectarium entire, and crenated.

3. The *nidus avis*, or *bird's neſt*, hath a bulbous, fibrated, cluſtered root: upright, thick, ſucculent ſtalks, a foot high, ſheathed by the leaves, and terminated by looſe ſpikes of pale brown flowers: having the lip of the nectarium bifid.

4. The *anthropophora, man-ſhaped ophrys*, or *man-orchis*, hath a roundiſh bulbous root, crowned with three or four oblong leaves; upright thick ſtalks, riſing a foot and a half high; adorned with narrow leaves, and terminated by looſe ſpikes of greeniſh flowers, repreſenting the figure of a naked man; the lip of the nectarium linear tripartite, with the middle ſegment longeſt and bifid. There is a variety with browniſh flowers tinged with green.

5. The *inſectifera*, or *inſect-orchis*, hath two roundiſh bulbous roots, crowned with oblong leaves; erect leafy ſtalks, from ſix to 10 or 12 inches high, terminated by ſpikes of inſect-ſhaped greeniſh flowers, having the lip of the nectarium almoſt five-lobed. This wonderful ſpecies exhibits flowers in different varieties, that repreſent ſingular figures of flies, bees, and other inſects; and are of different colours in the varieties.

6. The *monorchis*, or *muſky ophrys*, hath a roundiſh bulbous root; crowned with three or four oblong leaves; an erect naked ſtalk, ſix inches high; terminated by a looſe ſpike of yellowiſh, muſky ſcented flowers.

All theſe ſix ſpecies of ophrys flower in ſummer, at different times in different ſorts, from May until July; and in moſt of the ſorts exhibit a ſingularly curious appearance. The plants are all perennial in root, which are of the bulbous fleſhy kind, from which the flower-ſtalks riſe annually in ſpring, and decay in autumn; at which period is the proper time for removing the roots from one place to another. They all grow wild in Britain, &c.; are reſidents of woods, bogs, marſhy grounds, ſterile paſtures, chalky ſoils, and the like places, where they flouriſh and diſplay their ſingular flowers in great abundance, from which places they are introduced into gardens for variety; and having procured ſome plants at the proper ſeaſon, and planted them in ſoils and ſituations ſomewhat ſimilar to that where they naturally grow, the roots will abide for ſeveral years, and flower annually.

As to their propagation, it may be tried by ſeed in a ſhady border, as ſoon as it is ripe; likewiſe by offſets from the root, though they multiply ſparingly in gardens: however, roots of ſome ſtanding may be examined at the proper ſeaſon, and any offſets ſeparated and planted in the proper places.

OPHTHALMOSCOPY, a branch of phyſiognomy, which deduces the knowledge of a man's temper and manner from the appearance of his eyes.

OPHTHALMIA, in medicine, an inflammation of the membranes which inveſt the eye; eſpecially of the adnata, or albugineous coat. See MEDICINE, Nº 175.

OPIATES, medicines of a thicker conſiſtence than a ſyrup, prepared with opium ſcarcely fluid. They conſiſt of various ingredients, made up with honey or ſyrup; and are to be uſed for a long time either for purgative, alterative, or corroborative intentions.

The word *opiate* is alſo uſed, in general, for any medicine given with an intention to procure ſleep, whether in the form of electuaries, drops, or pills.

OPINION is that judgment which the mind forms of any propoſition for the truth or falſehood of which there is not ſufficient evidence to produce ſcience or abſolute belief.

That the three angles of a plane triangle are equal to two right angles, is not a matter of *opinion*, nor can it with propriety be called an object of the mathematician's *belief:* he does more than belive it; he *knows* it to be true. When two or three men, under no temptation to deceive, declare that they were witneſſes of an uncommon, though not preternatural event, their teſtimony is complete evidence, and produces abſolute *belief* in the minds of thoſe to whom it is given;

but it does not produce *ſcience* like rigid demonſtration. The fact is not doubted, but thoſe who have it on report do not *know* it to be true, as they know the truth of propoſitions intuitively or demonſtrably certain. When one or two men relate a ſtory including many circumſtances to a third perſon, and another comes who poſitively contradicts it either in whole or in part, he to whom thoſe jarring teſtimonies are given, weighs all the circumſtances in his own mind, balances the one againſt the other, and lends an aſſent, more or leſs wavering, to that ſide on which the evidence appears to preponderate. This aſſent is his *opinion* reſpecting the facts of which he has received ſuch different accounts*.

Opinions are often formed of events not yet in being. Were an officer from the combined armies, which are juſt now † beſieging Valenciennes, to come into the room where we are writing, and tell us that thoſe armies are in good health and high ſpirits; that every ſhot which they fire upon the fortreſs produces ſome effect; and that they have plenty of excellent proviſions, whilſt the beſieged are periſhing by hunger; we ſhould abſolutely *believe* every fact which he had told us upon the evidence of his teſtimony; but we could only be of *opinion* that the garriſon muſt ſoon ſurrender. In forming opinions of this kind, upon which, in a great meaſure depends our ſucceſs in any purſuit, every circumſtance ſhould be carefully attended to, and our judgments guided by former experience. Truth is a thing of ſuch importance to man, that he ſhould always purſue the beſt methods for attaining it; and when the object eludes all his reſearches, he ſhould remedy the diſappointment, by attaching himſelf to that which has the ſtrongeſt reſemblance to it; and that which moſt reſembles truth is called *probability*, as the judgment which is formed of it is termed *opinion*. See Probability.

† July 1793.

OPITS, or **Opitius** (Martin), a celebrated German poet, born at Breſlaw. He acquired great fame by his Latin, and more by his German poems; and, retiring to Dantzic, wrote a hiſtory of the ancient Daci: he died of the plague in 1639.

Opits (Henry), a learned Lutheran divine, born at Altenburg in Miſnia in 1642. He was profeſſor of theology and of the oriental languages at Kiel, where he acquired great reputation by a variety of excellent works concerning oriental literature and Hebrew antiquities. He died in 1712.

OPIUM, in the materia medica, is an inſpiſſated juice, partly of the reſinous and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a denſe texture, and not perfectly dry; but, in general, eaſily receives an impreſſion from the finger: its colour is a browniſh yellow, ſo very dark and duſky that at firſt it appears black: it has a dead and faint ſmell, and its taſte is very bitter and acrid. It is to be choſen moderately firm, and not too ſoft; its ſmell and taſte ſhould be very ſtrong, and care is to be taken that there be no dirty or ſtony matter in it.

Opium is the juice of the papaver album, or white poppy, with which the fields of Aſia Minor are in many places ſown, as ours are with corn. When the heads are near ripening, they wound them with an inſtrument that has five edges, which on being ſtuck into the head makes at once five long cuts in it; and from theſe wounds the opium flows, and is next day taken off by a perſon who goes round the field, and put up in a veſſel which he carries faſtened to his girdle; at the ſame time that this opium is collected, the oppoſite ſide of the poppy head is wounded, and the opium collected from it the next day. They diſtinguiſh, however, the produce of the firſt wounds from that of the ſucceeding ones; for the firſt juice afforded by the plant is greatly ſuperior to what is obtained afterwards. After they have collected the opium, they moiſten it with a ſmall quantity of water or honey, and work it a long time upon a flat, hard, and ſmooth board, with a thick and ſtrong inſtrument of the ſame wood, till it becomes of the conſiſtence of pitch; and then work it up with their hands, and form it into cakes or rolls for ſale.

Opium at preſent is in great eſteem, and is one of the moſt valuable of all the ſimple medicines. In its effects on the animal ſyſtem, it is the moſt extraordinary ſubſtance in nature. It touches the nerves as it were by magic and irreſiſtible power, and ſteeps the ſenſes in forgetfulneſs; even in oppoſition to the determined will of the philoſopher or phyſiologiſt, appriſed of its narcotic effect.

Leake's E ſay on the Diſeaſes o the Viſcer

The modification of matter is infinite; and who ſhall truly ſay by what peculiar or ſpecific configuration of its parts, opium, even in the quantity of a ſingle grain, adminiſtered to the human body, ſhall aſſuage the moſt raging pain, and procure profound ſleep?

The action of matter upon matter, thus exemplified in the effect of opium on the animal ſyſtem, is not leſs aſtoniſhing and incomprehenſible, than that of ſpirit upon matter, or the agency of mind on the motive powers of the body.

The firſt effects of opium are like thoſe of a ſtrong, ſtimulating cordial, but are ſoon ſucceeded by univerſal languor or irreſiſtible propenſity to ſleep, attended with dreams of the moſt rapturous and enthuſiaſtic kind. After thoſe contrary effects are over, which are generally terminated by a profuſe ſweat, the body becomes cold and torpid; the mind penſive and deſponding; the head is affected with ſtupor, and the ſtomach with ſickneſs and nauſea.

It is not our buſineſs, neither is it in our power, to reconcile that diverſity of opinion which has lately prevailed concerning the manner in which opium produces its effects; or to determine whether it acts ſimply on the brain and nerves, or, according to the experiments of Fontana, on the maſs of blood only.

Opium is the moſt ſovereign remedy in the materia medica, for eaſing pain and procuring ſleep, and alſo the moſt certain antiſpaſmodic yet known; but, like other powerful medicines, becomes highly noxious to the human conſtitution, and even mortal, when improperly adminiſtered. Its liberal and long-continued uſe has been obſerved greatly to injure the brain and nerves, and to diminiſh their influence on the vital organs of the body. By its firſt effects, which are exhilarating, it excites a kind of temporary delirium, which diſſipates and exhauſts the ſpirits: and, by its ſubſequent narcotic power, occaſions confuſion of ideas and loſs of memory, attended with nauſea, giddineſs, Opium. headach, and conſtipation of the bowels; in a word, it ſeems to ſuſpend or diminiſh all the natural ſecretions and excretions of the body, that of perſpiration only excepted.

Thoſe who take opium to exceſs become enervated and ſoon look old; when deprived of it, they are faint, and experience the languor and dejection of ſpirits common to ſuch as drink ſpirituous liquors in exceſs; to the bad effects of which it is ſimilar, ſince, like thoſe, they are not eaſily removed without a repetition of the doſe.

By the indiſcriminate uſe of that preparation of opium called *Godfrey's cordial*, many children are yearly cut off; for it is frequently given doſe after doſe, without moderation, by ignorant women and mercenary nurſes, to ſilence the cries of infants and lull them to ſleep, by which they are at laſt rendered ſtupid, inactive, and rickety.

Opium is univerſally known to be uſed as a luxury in the Eaſt. Mr Groſe informs us, that moſt of the hard labouring people at Surat, and eſpecially the porters, take great quantities of this drug, which, they pretend, enables them to work, and carry heavier burdens than they otherwiſe could do. Some of theſe, our author aſſures us, will take more than an ounce at a time without detriment. Many people in opulent circumſtances follow the ſame cuſtom, but with very different motives. Some uſe it merely for the ſake of the pleaſing delirium it occaſions; others for venereal purpoſes, as by this means they can lengthen the amorous congreſs as much as they pleaſe, though they thus are certain to bring on an abſolute impotency and premature old age at laſt. For this purpoſe it is uſually taken in milk; and when they have a mind to check or put an end to its operation, they ſwallow a ſpoonful or two of lime juice, or any ſimilar acid.

Beſides theſe effects of opium, it is ſaid by the Indians to have a very ſingular one in bringing on a ſeeming heavineſs of the head and ſleepineſs of the eye, at the ſame time that it really produces great watchfulneſs. It is alſo conſidered as a great inſpirer of courage, or rather inſenſibility to danger; ſo that the commanders make no ſcruple of allowing large quantities of it to the ſoldiers when they are going to battle or engaged in any hazardous enterpriſe.

The beſt opium in the world is ſaid to come from Patna on the river Ganges, where, at leaſt, the greateſt traffic of it is made, and from whence it is exported all over India; though in ſome parts, eſpecially on the Malay coaſts, it is prohibited under pain of death, on account of the madneſs, and murders conſequent upon that madneſs, which are occaſioned by it; notwithſtanding which ſevere prohibition, however, it is plentifully ſmuggled into all theſe countries.—The ſoil about the Ganges is accounted beſt for producing the ſtrongeſt kind of opium; of which the following remarkable inſtance is related. "A nabob of theſe parts having invited an Engliſh factory to an entertainment, a young gentleman, a writer in the Company's ſervice, ſauntering about the garden, plucked a poppy and ſucked the head of it. In conſequence of this he fell into a profound ſleep; of which the nabob being appriſed, and likewiſe informed of the particular bed out of which he had taken the flower, expreſſed his ſorrow; acquainting his friends at the ſame time that the poiſon was too ſtrong to admit of any remedy; which accordingly proved true, and the unfortunate gentleman never awaked."

Opium applied externally is emollient, relaxing, and diſcutient, and greatly promotes ſuppuration: if long kept upon the ſkin, it takes off the hair, and always occaſions an itching in it: ſometimes it exulcerates it, and raiſes little bliſters, if applied to a tender part. Sometimes, on external application, it allays pain, and even occaſions ſleep: but it muſt by no means be applied to the head, eſpecially to the ſutures of the ſkull; for it has been known to have the moſt terrible effects in this application, and even to bring on death itſelf.

An experimental inquiry into the properties of opium, &c.

It appears, too, from ſome curious experiments made by Dr Leigh, to act as the moſt powerful of all ſtyptics. "Having laid bare the crural artery of a rabbit (ſays the Doctor), I divided it, when the blood inſtantly flew out with conſiderable velocity; ſome of a ſtrong ſolution was then applied to the divided artery, the ends of which in a ſhort ſpace of time contracted, and the hæmorrhagy ceaſed. The ſame experiment was performed on the brachial artery with like ſucceſs."

The effects of a ſtrong ſolution of opium upon the heart, appears from the ſame experiments to be very extraordinary. "I opened the thorax of a rabbit (ſays the Doctor), and by diſſection placed the heart in full view; the aorta was then divided, and the animal bled till it expired. After the heart had remained motionleſs ten minutes, and every appearance of life had ceaſed for the ſame length of time, I poured on the heart a quantity of my ſtrong ſolution; it was inſtantly thrown into motion, which continued two minutes: I then added more of the ſolution, and the action was again renewed. By thus repeating my applications, the motions of the heart were ſupported more than ten minutes. I afterwards opened the thorax of a rabbit, and, without doing any injury to the large blood veſſels, placed the heart in view. A quantity of my ſtrong ſolution was then applied to it, which ſo accelerated the motions as to render it impoſſible to number them: by renewing the application, theſe were continued for ſome conſiderable time. The ſurface of the heart now appeared uncommonly red, and continued ſo ſome time."

Opium contains gum, reſin, eſſential oil, ſalt, and earthy matter; but its *narcotic* or ſomniferous power has been experimentally found to reſide in its *eſſential oil*.

Opium, Opobalſamum.

OPOBALSAMUM, in the materia medica. Opobalſam, or balm of Gilead. See Amyris.

Mr Bruce, the celebrated traveller, whom we have frequently had occaſion to introduce to our readers with that praiſe to which we think his labours have fully entitled him, employs ſeveral pages of his Appendix in aſcertaining the antiquity and native ſoil of the balſam tree, with other particulars of that nature; after which he gives us the following account of the opobalſamum, or juice flowing from it: "At firſt when it is received into the bottle or vaſe from the wound from whence it iſſues, it is of a light yellow colour, apparently turbid, in which there is a whitiſh caſt, which I apprehend are the globules of air that pervade the whole of it in its firſt ſtate of fermentation; it then appears very light upon ſhaking. As it ſettles and cools, it turns clear, and loſes that milkineſs which it firſt had when flowing from the tree into the bottle. It then has the colour of honey, and appears more fixed and heavy than at firſt. After being kept for years, it grows a much deeper yellow, and of the colour of gold. I have ſome of it, which, as I have already mentioned in my Travels, I got from the cadi of Medina in the 1768; it is now ſtill deeper in colour, full as much ſo as the yelloweſt honey. It is perfectly fluid, and has loſt very little either of its taſte, ſmell, or weight. The ſmell at firſt is violent and ſtrongly pungent, giving a ſenſation to the brain like to that of volatile ſalts when raſhly drawn up by an incautious perſon. This laſts in proportion to its freſhneſs; for being neglected, and the bottle uncorked, it quickly loſes this quality, as it probably will at laſt by age, whatever care is taken of it.

"In its pure and freſh ſtate it diſſolves eaſily in water. If dropped on a woollen cloth, it will waſh out eaſily, and leaves no ſtain. It is of an acrid, rough, pungent taſte; is uſed by the Arabs in all complaints of the ſtomach and bowels, is reckoned a powerful antiſeptic, and of uſe in preventing any infection of the plague. Theſe qualities it now enjoys, in all probability, in common with the various balſams we have received from the new world, ſuch as the balſam of Tolu, of Peru, and the reſt; but it is always uſed, and in particular eſteemed by the ladies as a coſmetic: As ſuch it has kept up its reputation in the eaſt to this very day. The manner of applying it is this: You firſt go into the tepid bath till the pores are ſufficiently opened: you then anoint yourſelf with a ſmall quantity, and as much as the veſſels will abſorb. Never-fading youth and beauty are ſaid to be the conſequences of this. The purchaſe is eaſy enough. I do not hear that it ever has been thought reſtorative after the loſs of either."

OPOCALPASUM, Opocarbasum, or Apocalpasum; a gummy reſinous ſubſtance, which has a ſtrong reſemblance to the beſt liquid myrrh, and which in the time of Galen they mixed with myrrh. It was difficult, according to this writer, to diſtinguiſh the one from the other unleſs by their effects. It was a poiſonous juice, which frequently produced lethargy and ſudden ſtrangling. He declares that he has known ſeveral perſons who died in conſequence of inadvertently taking myrrh in which there was a mixture of opocarbaſum. Perhaps it was only a juice compoſed of a ſolution of euphorbia, in which drops of opium were macerated. Poiſons of this kind have from time immemorial been as common in Africa as that of arrows poiſoned with the juice of the mancanilla is in America.

Mr Bruce, the Abyſſinian traveller, ſays that he ſaw in a Mahometan village a large tree, which was ſo covered with knots and balls of gum on the upper part of the trunk and on the large branches, that it had a monſtrous appearance. From ſome inquiries which he made on this ſubject, he found that certain merchants had brought this tree from the country of the good myrrh, which is Troglodytria (for it does not grow in Arabia), and that they had planted it for the ſake of its gum; with which theſe Muſſulmans ſtarch the blue ſtuffs of Surat, which they receive damaged from Mocha, in order to barter them with the Galla and the Abyſſinians. This tree is called *ſaſſa*; and Mr Bruce declares that he has ſeen it completely covered with beautiful crimſon flowers of a very uncommon ſtructure. The ſame traveller obſerves, that the ſaſſa gum is well calculated, both on account of its abundance and its colour, to augment the quantity of myrrh; and he is the more confirmed in his opinion, becauſe every thing leads him to think that no other gummiferous tree, poſſeſſed of the ſame properties with the ſaſſa, grows in the myrrh country. In ſhort, he thinks it almoſt beyond a doubt that the gum of the ſaſſa tree is the opocalpaſum; and he ſuppoſes Galen miſtaken in aſcribing any fatal property to this drug; and that many were believed to be killed by it, whoſe death might, perhaps, with more juſtice, have been placed to the account of the phyſician. Mr Bruce adds, that though the Troglodites of the myrrh country are at preſent more ignorant than formerly, they are nevertheleſs well acquainted with the properties of their ſimples: and that while they wiſh to increaſe the ſale of their commodities, they would never mix with them a poiſon which muſt neceſſarily diminiſh it. In this we accede to his opinion; but we muſt differ from him when he ſays that no gum or reſin with which we are acquainted is a mortal poiſon: the ſavages of both hemiſpheres are acquainted with but too many of them. The gum of the ſaſſa tree, according to Mr Bruce, is of a cloſe ſmooth grain, of a brown dull colour, but ſometimes very tranſparent; it ſwells and becomes white in water; it has a great reſemblance in its properties to gum tragacanth, and may be eaten with all ſafety. From all this it appears that the opocalpaſum mentioned by Pliny is not the ſaſſa gum deſcribed by Mr Bruce.

OPOPANAX, in the materia medica, is a gum-reſin of a tolerably firm texture, uſually brought to us in looſe granules or drops, and ſometimes in large maſſes, formed of a number of theſe connected by a quantity of matter of the ſame kind; but theſe are uſually loaded with extraneous matter, and are greatly inferior to the pure looſe kind. The drops or granules of the fine opopanax are on the outſide of a browniſh red colour, and of a duſky yellowiſh or whitiſh colour within: they are of a ſomewhat unctuous appearance, ſmooth on the ſurface; and are to be choſen in clear pieces, of a ſtrong ſmell and acrid taſte.

This gummy ſubſtance is obtained from the roots of an umbelliferous plant, which grows ſpontaneouſly in the warmer countries, and bears the colds of this. The juice is brought from Turkey and the Eaſt Indies; and its virtues are thoſe of an attenuating and aperient medicine. Boerhaave frequently employed it, along with ammoniacum and galbanum, in hypochondriacal diſorders, obſtructions of the abdominal viſcera, and ſuppreſſions of [illegible] menſtrual evacuations from a ſluggiſhneſs of mucous humours, and a want of due elaſticity of the ſolids: [illegible] theſe intentions it is an uſeful ingredient in the pilulæ gummoſæ and compound powder of myrrh of the London Pharmacopœia, but it is not employed in any compoſition of the Edinburgh.—It may be given by itſelf in the doſe of a ſcruple, or half a drachm: a whole drachm proves in many conſtitutions gently purgative: alſo diſpels flatulencies, is good in aſthmas, in inveterate coughs, and in diſorders of the head and nerves.

Doctor Woodville, in his Medical Botany, gives the following account of this vegetable: "It is of the *digynia* order, and *pentandria* claſs of plants: the root is

Opoponax,
a species of Pastinaca.

perennial, thick, fleſhy, tapering like the garden parſnep: the ſtalk is ſtrong, branched rough towards the bottom, and riſes ſeven or eight feet in height; the leaves are pinnated, conſiſting of ſeveral pairs of pinnæ, which are oblong, ſerrated, veined, and towards the baſe appear unformed on the upper ſide: the flowers are ſmall, of a yellowiſh colour, and terminate the ſtem and branches in flat umbels; the general and partial umbels are compoſed of many radii; the general and partial involucra are commonly both wanting; all the florets are fertile, and have an uniform appearance; the petals are five, lance-ſhaped, and curled inwards; the five filaments are ſpreading, curved, longer than the petals, and furniſhed with roundiſh antheræ; the germen is placed below the corolla, ſupporting two reflexed ſtyles, which are ſupplied with blunt ſtigmata; the fruit is elliptical, compreſſed, divided into two parts, containing two flat ſeeds, encompaſſed with a narrow border. See Plate CCCLI. It is a native of the ſouth of Europe, and flowers in June and July.

"This ſpecies of parſnep was cultivated in 1731 by Mr P. Miller, who obſerves, that its 'roots are large, ſweet, and accounted very nouriſhing,' therefore recommended for cultivation in kitchen gardens. It bears the cold of our climate very well, and commonly maturates its ſeeds, and its juice here manifeſts ſome of thoſe qualities which are diſcovered in the officinal opopanax; but it is only in the warm regions of the eaſt, and where this plant is a native, that its juice concretes into this gummy reſinous drug. Opopanax is obtained by means of inciſions made at the bottom of the ſtalk of the plant, from whence the juice gradually exudes; and by undergoing ſpontaneous concretion, aſſumes the appearance under which we have it imported from Turkey and the Eaſt Indies. It readily mingles with water, by triture, into a milky liquor, which on ſtanding depoſites a portion of reſinous matter, and becomes yellowiſh: to rectified ſpirit it yields a gold-coloured tincture, which taſtes and ſmells ſtrongly of opopanax. Water diſtilled from it is impregnated with its ſmell, but no eſſential oil is obtained on committing moderate quantities to the operation." See Pastanaca, of which opopanax is a ſpecies.

OPORTO, or Porto; a rich, handſome, and conſiderable town of Portugal, in the province of Entre Douro e Minho, with a biſhop's ſee. It is a place of great importance, and by nature almoſt impregnable. It is noted for its ſtrong wines; and a large quantity is from thence exported into Britain, whence all red wines that come from Spain or Portugal are called *port wines*. It is ſeated on the declivity of a mountain near the river Duero, which forms an excellent harbour. W. Long. 8. 1. N. Nat. 41. 0.

OPOSSUM, in zoology. See Didelphis.

OPPENHEIM, a town of Germany, in the lower palatinate of the Rhine, and capital of a bailiwick of the ſame name; ſeated on the declivity of a hill near the Rhine. E. Long. 8. 20. N. Lat. 49. 48.

OPPIANUS, a poet and grammarian of Anazarba in Cilicia, in the ſecond century. He compoſed a poem of hunting, and another of fiſhing, for which Antoninus Caracalla gave him as many golden crowns as there were verſes in his poems; they were hence called *Oppian's golden verſes*. He died in the 30th year of his age.

OPPILATION, in medicine, the act of obſtructing or ſtopping up the paſſage of the body, by redundant or peccant humours. This word is chiefly uſed for obſtructions in the lower belly.

OPTATIVE mood, in grammar, that which ſerves to expreſs an ardent deſire or wiſh for ſomething.

In moſt languages, except the Greek, the optative is only expreſſed by prefixing to the ſubjunctive an adverb of wiſhing: as *utinam*, in Latin; *plut à Dieu*, in French; and *would to God*, in Engliſh.

OPTIC angle, the angle which the optic axes of both eyes make with one another, as they tend to meet at ſome diſtance before the eyes.

Optic *Axis*, the axis of the eye, or a line going through the middle of the pupil and the centre of the eye.

OPTICS,

THAT ſcience which treats of the element of light, and the various phenomena of viſion.

HISTORY.

§ 1. *Diſcoveries concerning the Light.*

1 Difficulties attending the explanation of the phenomena of

The element of Light has occupied much of the attention of thinking men ever ſince the phenomena of nature have been the objects of rational inveſtigation. The diſcoveries that have from time to time been made concerning it, are ſo fully inſerted under the article Light, that there is little room for any further addition here. The nature of that ſubtile element is indeed very little known as yet, notwithſtanding all the endeavours of philoſophers; and whatever ſide is taken with regard to it, whether we ſuppoſe it to conſiſt of an infinity of ſmall particles propagated by a repulſive power from the luminous body, or whether we ſuppoſe it to conſiſt in the vibrations of a ſubtile fluid, there are prodigious difficulties, almoſt, if not totally inſuperable, which will attend the explanation of its phenomena. In many parts of this work the identity of light and of the electric fluid is aſſerted: this, however, doth not in the leaſt interfere with the phenomena of optics; all of which are guided by the ſame invariable laws, whether we ſuppoſe light to be a vibration of that fluid, or any thing elſe. We ſhall therefore proceed to,

§ 2. *Diſcoveries concerning the Refraction of Light.*

2 Refraction known to the ancients;

We find that the ancients, though they made very few optical experiments, nevertheleſs knew, that when light paſſed through mediums of different denſities, it did not move forward in a ſtraight line, but was bent or *refracted*, out of its courſe. This was probably ſuggeſted to them by the appearance of a ſtraight ſtick partly immerſed in water; and we find many queſtions concerning this and other optical appearances in Ariſtotle; to which, however, his anſwers are inſignificant. Archimedes is even ſaid to have written a treatiſe concerning the appearance of a ring or circle under water, and therefore could not have been ignorant of the common phenomena of refraction. But the ancients were not only acquainted with theſe more ordinary appearances of refraction, but knew alſo the production of colours by refracted light. Seneca ſays, that if the light of the ſun ſhines through an angular piece of glaſs, it will ſhow all the colours of the rainbow. Theſe colours, however, he ſays, are falſe, ſuch as are ſeen in a pigeon's neck when it changes its poſition; and of the ſame nature, he ſays, is a ſpeculum, which, without having any colour of its own, aſſumes that of any other body. It appears alſo, that the ancients were not unacquainted with the magnifying power of glaſs globes filled with water, though they do not ſeem to have known any thing of the reaſon of this power; and the ancient engravers are ſuppoſed to have made uſe of a glaſs globe filled with water to magnify their figures, and thereby to work to more advantage. That the power of tranſparent bodies of a ſpherical form in magnifying or burning was not wholly unknown to the ancients, is further probable from certain gems preſerved in the cabinets of the curious, which are ſuppoſed to have belonged to the Druids. They are made of rock cryſtal, of various forms, amongſt which are found ſome that are lenticular and others that are ſpherical: and though they are not ſufficiently wrought to perform their office as well as they might have done if they had been more judiciouſly executed, yet it is hardly poſſible that their effect, in magnifying at leaſt, could have eſcaped the notice of thoſe who had often occaſion to handle them; if indeed, in the ſpherical or lenticular form, they were not ſolely intended for the purpoſes of burning. One of theſe, of the ſpherical kind, of about an inch and a half diameter, is preſerved among the foſſils given to the univerſity of Cambridge by Dr Woodward.

3
and the magnifying power of glaſs globes.

The firſt treatiſe of any note written on the ſubject of optics, was by the celebrated aſtronomer Claudius Ptolemæus, who lived about the middle of the ſecond century. The treatiſe is loſt; but from the accounts of others we find that he treated of aſtronomical refractions.

4
Refraction firſt treated ſcientifically by Ptolemy.

Though refraction in general had been obſerved very early, it is poſſible that it might not have occurred to any philoſopher much before his time, that the light of the ſun, moon, and ſtars, muſt undergo a ſimilar refraction in conſequence of falling obliquely upon the groſs atmoſphere that ſurrounds the earth; and that they muſt, by that means, be turned out of their rectilinear courſe, ſo as to cauſe thoſe luminaries to appear higher in the heavens than they would otherwiſe do. The firſt aſtronomers were not aware that the intervals between ſtars appear leſs near the horizon than near the meridian; and, on this account, they muſt have been much embarraſſed in their obſervations. But it is evident that Ptolemy was aware of this circumſtance, by the caution that he gives to allow ſomething for it, upon every recourſe to ancient obſervations.

5
His hypotheſis concerning the horizontal ſun and moon.

This philoſopher alſo advances a very ſenſible hypotheſis to account for the remarkably greater apparent ſize of the ſun and moon when ſeen near the horizon. The mind, he ſays, judges of the ſize of objects by means of a preconceived idea of their diſtance from us: and this diſtance is fancied to be greater when a number of objects are interpoſed between the eye and the body we are viewing; which is the caſe when we ſee the heavenly bodies near the horizon. In his Almageſt, however, he aſcribes this appearance to a refraction of the rays by vapours, which actually enlarge the angle under which the luminaries appear; juſt as the angle is enlarged by which an object is ſeen from under water.

In the 12th century, the nature of refraction was largely conſidered by Alhazen an Arabian writer; inſomuch that, having made experiments upon it at the common ſurface between air and water, air and glaſs, water and glaſs or cryſtal; and, being prepoſſeſſed with the ancient opinion of cryſtalline orbs in the regions above the atmoſphere, he even ſuſpected a refraction there alſo, and fancied he could prove it by aſtronomical obſervations.

6
Diſcoveries of Alhazen

This author deduces from hence ſeveral properties of atmoſpherical refraction, as that it increaſes the altitudes of all objects in the heavens; and he firſt advanced, that the ſtars are ſometimes ſeen above the horizon by means of refraction, when they are really below it. This obſervation was confirmed by Vitellio, B. Waltherus, and eſpecially by the excellent obſervations of Tycho Brahe. Alhazen obſerved, that refraction contracts the vertical diameters and diſtances of the heavenly bodies, and that it is the cauſe of the twinkling of the ſtars. But we do not find that either he, or his follower Vitellio, knew any thing of its juſt quantity. Indeed it is too ſmall to be determined except by very accurate inſtruments, and therefore we hear little more of it till about the year 1500; at which time great attention was paid to it by Bernard Walther, Mæſtlin, and others, but chiefly by Tycho Brahe.

Alhazen ſuppoſed that the refraction of the atmoſphere did not depend upon the vapours in it, as was probably the opinion of philoſophers before his time, but on the different tranſparency; by which, as Montucla conjectures, he meant the denſity of the groſs air contiguous to the earth, and the ether or ſubtile air that lies beyond it. In examining the effects of refraction, he endeavours to prove that it is ſo far from being the cauſe of the heavenly bodies appearing larger near the horizon, that it would make them appear leſs; two ſtars, he ſays, appearing nearer together in the horizon, than near the meridian. This phenomenon he ranks among optical deceptions. We judge of diſtance, he ſays, by comparing the angle under which objects appear, with their ſuppoſed diſtances; ſo that if theſe angles be nearly equal, and the diſtance of one object be conceived greater than that of the other, it will be imagined to be larger. And the ſky near the horizon, he ſays, is always imagined to be further from us than any other part of the concave ſurface. Roger Bacon aſcribes this account of the horizontal moon to Ptolemy; and as ſuch it is examined, and objected to by B. Porta.

In the writings of this Bacon, whoſe genius perhaps equalled that of his great nameſake Lord Verulam, we find the firſt diſtinct account of the magnifying power of glaſſes; and it is not improbable, that what he wrote upon this ſubject gave riſe to that moſt uſeful invention of ſpectacles. For he ſays, that if an object be applied cloſe to the baſe of the large ſegment of a ſphere of glaſs, it will appear magnified. He alſo treats of the appearance of an object through a globe, and ſays that he was the firſt who obſerved the refraction of rays into it.

7 Of Vitellio. In 1270, Vitellio, a native of Poland, publiſhed a treatiſe of optics, containing all that was valuable in Alhazen, and digeſted in a much more intelligible and methodical manner. He obſerves, that light is always loſt by refraction, in conſequence of which the objects ſeen by refracted light always appear leſs luminous; but he does not pretend to eſtimate the quantity of this loſs. He reduced into a table the reſult of his experiments on the refractive powers of air, water, and glaſs, correſponding to different angles of incidence. In his account of the horizontal moon he agrees exactly with Alhazen: obſerving, that in the horizon ſhe ſeems to touch the earth, and appears much more diſtant from us than in the zenith, on account of the intermediate ſpace containing a greater variety of objects upon the viſible ſurface of the earth. He aſcribes the twinkling of the ſtars to the motion of the air in which the light is refracted; and to illuſtrate this hypotheſis, he obſerves, that they twinkle ſtill more when viewed in water put in motion. He alſo ſhows, that refraction is neceſſary as well as reflection, to form the rainbow; becauſe the body which the rays fall upon is a tranſparent ſubſtance, at the ſurface of which one part of the light is always reflected and another refracted. But he ſeems to conſider refraction as ſerving only to condenſe the light, and thereby enabling it to make a ſtronger impreſſion upon the eye. This writer makes alſo many ingenious attempts to explain refraction, or to aſcertain the law of it. He alſo conſiders the foci of glaſs ſpheres, and the apparent ſize of objects ſeen through them: though upon theſe ſubjects he is not at all exact. It is ſufficient indeed to ſhow the ſtate of knowledge, or rather of ignorance, at that time, to obſerve, that both Vitellio, and his maſter Alhazen, endeavour to account for objects appearing larger when they are ſeen under water by the circular figure of its ſurface; ſince, being fluid, it conforms to the figure of the earth.

Of Roger Bacon. Contemporary with Vitellio was Roger Bacon, a man of very extenſive genius, and who wrote upon almoſt every branch of ſcience; yet in this branch he does not ſeem to have made any conſiderable advances beyond what Alhazen had done before him. Even ſome of the wildeſt and moſt abſurd of the opinions of the ancients have had the ſanction of his authority. He does not heſitate to aſſent to an opinion [illegible] many of the ancients, and indeed by moſt [illegible]ers till his time, that viſual rays proceed from the eye; giving this reaſon for it, that every thing in nature is qualified to diſcharge its proper functions by its own powers, in the ſame manner as the ſun and other celeſtial bodies. In his *Specula Mathematica*, he added ſome obſervations on the refraction of the light of the ſtars; the apparent ſize of objects; the extraordinary ſize of the ſun and moon in the horizon: but in all this he is not very exact, and advances but little. In his *Opus Majus* he demonſtrates, that if a tranſparent body interpoſed between the eye and an object, be convex towards the eye, the object will appear magnified. This obſervation, however, he certainly had from Alhazen; the only difference between them is, that Bacon prefers the ſmaller ſegment of a ſphere, and Alhazen the larger, in which the latter certainly was right.

From this time, to that of the revival of learning in Europe, we have no farther treatiſe on the ſubject of refraction, or indeed on any other part of optics. 9 Of Maurolycus. One of the firſt who diſtinguiſhed himſelf in this way was Maurolycus, teacher of mathematics at Meſſina. In a treatiſe, *De Lumine et Umbra*, publiſhed in 1575, he demonſtrates that the cryſtalline humour of the eye is a lens that collects the rays of light iſſuing from the objects and throws them upon the retina where is the focus of each pencil. From this principle he diſcovered the reaſon why ſome people were ſhort-ſighted and others long-ſighted; and why the former are relieved by concave, and the others by convex, glaſſes.

10 Diſcoveries of B. Porta. About the ſame time that Maurolycus made ſuch advances towards the diſcovery of the nature of viſion, Joannes Baptiſta Porta of Naples diſcovered the *camera obſcura*, which throws ſtill more light on the ſame ſubject. His houſe was conſtantly reſorted to by all the ingenious perſons at Naples, whom he formed into what he called *an academy of ſecrets*; each member being obliged to contribute ſomething that was not generally known, and might be uſeful. By this means he was furniſhed with materials for his *Magia Naturalis*, which contains his account of the *camera obſcura*, and the firſt edition of which was publiſhed, as he informs us, when he was not quite 15 years old. He alſo gave the firſt hint of the magic lantern; which Kircher afterwards followed and improved. His experiments with the *camera obſcura* convinced him, that viſion is performed by the intromiſſion of ſomething into the eye, and not by viſual rays proceeding from the eye, as had been formerly imagined; and he was the firſt, who fully ſatisfied himſelf and others upon this ſubject. Indeed the reſemblance between experiments with the *camera obſcura* and the manner in which viſion is performed in the eye, was too ſtriking to eſcape the obſervation of a leſs ingenious perſon. But when he ſays that the eye is a *camera obſcura*, and the pupil the hole in the window ſhutter, he was ſo far miſtaken as to ſuppoſe that it was the cryſtalline humour that correſponds to the wall which receives the images; nor was it diſcovered till the year 1604, that this office is performed by the retina. He makes a variety of juſt obſervations concerning viſion; and particularly explains ſeveral caſes in which we imagine things to be without the eye, when the appearances are occaſioned by ſome affection of the eye itſelf, or ſome motion within the eye. He obſerves alſo, that, in certain circumſtances, viſion will be aſſiſted by convex or concave glaſſes; and he ſeems alſo to have made ſome ſmall advances towards the diſcovery of teleſcopes. He takes notice, that a round and flat ſurface plunged into water, will appear hollow as well as magnified to an eye perpendicularly over it; and he very well explains by a figure the manner in which it is done.

11 The law of refraction diſcovered. All this time, however, the great problem concerning the meaſuring of refractions had remained unſolved. Alhazen and Vitellio, indeed, had attempted it; but failed, by attempting to meaſure the angle itſelf inſtead of its ſine. At laſt it was diſcovered by Snellius, profeſſor of mathematics at Leyden. This philoſopher, however, did not perfectly underſtand his own diſcovery, nor did he live to publiſh any account of it himſelf. It was afterwards explained by Profeſſor Hortenſius both publicly and privately before

fore it appeared in the writings of Deſcartes, who publiſhed it under a different form, without making any acknowledgment of his obligations to Snellius, whoſe papers Huygens aſſures us, from his own knowledge, Deſcartes had ſeen. Before this time Kepler had publiſhed a New Table of refracted Angles, determined by his own experiments for every degree of incidence. Kircher had done the ſame, and attempted a rational or phyſical theory of refraction, on principles, and on a mode of inveſtigation, which, if conducted with preciſion, would have led him to the law aſſumed or diſcovered by Snellius.

12
Opinions of Deſcartes and Leibnitz on this ſubject.

Deſcartes undertook to explain the cauſe of refraction by the reſolution of forces, on the principles of mechanics. In conſequence of this, he was obliged to ſuppoſe that light paſſes with more eaſe through a denſe medium, than through a rare one. The truth of this explanation was firſt queſtioned by M. Fermat, counſellor to the parliament of Thoulouſe, and an able mathematician. He aſſerted, contrary to the opinion of Deſcartes, that light ſuffers more reſiſtance in water than air, and more in glaſs than in water; and he maintained, that the reſiſtance of different mediums with reſpect to light is in proportion to their denſities. M. Leibnitz adopted the ſame general idea; and theſe gentlemen argued upon the ſubject in the following manner:—

Nature, ſay they, accompliſhes her ends by the ſhorteſt methods. Light therefore ought to paſs from one point to another, either by the ſhorteſt road, or that in which the leaſt time is required. But it is plain that the line in which light paſſes, when it falls obliquely upon a denſer medium, is not the moſt direct or the ſhorteſt; ſo that it muſt be that in which the leaſt time is ſpent. And whereas it is demonſtrable, that light falling obliquely upon a denſer medium (in order to take up the leaſt time poſſible in paſſing from a point in one medium to a point in the other) muſt be refracted in ſuch a manner, that the ſines of the angles of incidence and refraction muſt be to one another, as the different facilities with which light is tranſmitted in thoſe mediums; it follows, that ſince light approaches the perpendicular when it paſſes obliquely from air into water, ſo that the ſine of the angle of refraction is leſs than that of the angle of incidence, the facility with which water ſuffers light to paſs through it is leſs than that of the air; ſo that light meets with more reſiſtance in water than air.

13
D[illegible]
[illegible]ferent
ſtances.

Arguments of this kind could not give ſatisfaction; and a little time ſhowed the fallacy of the hypotheſis. [illegible] meeting of the Royal Society, Aug. 31. 1664, an experiment for meaſuring the refraction of common water was made with a new inſtrument which they had prepared for that purpoſe; and, the angle of incidence being 40 degrees, that of refraction was found to be 30. About this time alſo we find the firſt mention of mediums not refracting the light in an exact proportion to their denſities. For Mr Boyle, in a letter to Mr Oldenburgh, dated Nov. 3. 1664, obſerves, that in ſpirit of wine, the proportion of the ſines of the angles of incidence to the ſines of the angles of refraction was nearly the ſame as 4 to 3; and that, as ſpirit of wine occaſions a greater refraction than common water, ſo oil of turpentine, which is lighter than ſpirit of wine, produces not only a greater refraction than common water, but a much greater than ſalt water. And at a meeting held Nov. 9. the ſame year, Dr Hooke (who had been ordered to proſecute the experiment) brought in an account of one that he had made with pure and clear ſalad oil, which was found to have produced a much greater refraction than any liquor which he had then tried; the angle of refraction that anſwered to an angle of incidence of 30° being found no leſs than 40° 30′, and the angle of refraction that anſwered to an angle of incidence of 20° being 29° 47′.—M. de la Hire alſo made ſeveral experiments to aſcertain the refractive power of oil with reſpect to that of water and air, and found the ſine of the angle of incidence to that of refraction to be as 60 to 42; which, he obſerves, is a little nearer to that of glaſs than to that of water, though oil is much lighter than water, and glaſs much heavier.

The members of the Royal Society finding that the refraction of ſalt water exceeded that of freſh, purſued the experiment farther with ſolutions of vitriol, ſaltpetre, and alum, in water; when they found the refraction of the ſolution of vitriol and ſaltpetre a little more, but that of alum a little leſs, than common water.

Dr Hooke made an experiment before the Royal Society, Feb. 11. 1663, which clearly proves that ice refracts the light leſs than water; which he took to be a good argument that the lightneſs of ice, which cauſes it to ſwim in water, is not cauſed only by the ſmall bubbles which are viſible in it, but that it ariſes from the uniform conſtitution or general texture of the whole maſs. M. de la Hire alſo took a good deal of pains to determine whether, as was then the common opinion, the refractive power of ice and water were the ſame; and he found as Dr Hooke had done before, that ice refracts leſs than water.

By a moſt accurate and elaborate experiment made in the year 1698, in which a ray of light was tranſmitted through a Torricellian vacuum, Mr Lowthorp found, that the refractive power of air is to that of water as 36 to 34,400. He concludes his account of the experiment with obſerving, that the refractive power of bodies is not proportioned to the denſity, at leaſt not to the gravity, of the refracting medium. For the refractive power of glaſs to that of water is as 55 to 34, whereas its gravity is as 87 to 34; that is, the ſquares of their refractive powers are very nearly as their reſpective gravities. And there are ſome fluids, which though they are lighter then water, yet have a greater power of refraction. Thus the refractive power of ſpirit of wine, according to Dr Hooke's experiment, is to that of water as 36 to 33, and its gravity reciprocally as 33 to 36, or 36½. But the refractive powers of air and water ſeem to obſerve the ſimple proportion of their gravities directly. And if this ſhould be confirmed by ſucceeding experiments, it is probable, he ſays, that the refractive powers of the atmoſphere are everywhere, and at all heights above the earth, proportioned to its denſity and expanſion; and then it would be no difficult matter to trace the light through it, ſo as to terminate the ſhadow of the earth ſound, together with proper expedients for meaſuring the quantity of light illuminating an opaque body, to examine at what diſtances the moon muſt be from the earth to ſuffer eclipſes of the obſerved durations.

Caſſini the younger happened to be preſent when Mr Lowthorp made the above-mentioned experiment before the Royal Society; and upon his return home, having made a report of it to the members of the Royal Academy of Sciences, thoſe gentlemen endeavoured to repeat the experiment in 1700; but they did not ſucceed.—For, as they ſaid, beams of light paſſed through the vacuum without ſuffering any refraction. The Royal Society being informed of this, were deſirous that it might be put paſt diſpute, by repeated and well atteſted trials; and ordered Mr Haukſbee to make an inſtrument for the purpoſe, by the direction of Dr Halley. It conſiſted of a ſtrong braſs prism, two ſides of which had ſockets to receive two plane glaſſes, whereby the air in the priſm might either be exhauſted or condenſed. The priſm had alſo a mercurial gage fixed to it, to diſcover the denſity of the contained air; and was contrived to turn upon its axis, in order to make the refractions equal on each ſide when it was fixed to the end of a teleſcope. The refracting angle was near 64°; and the length of the teleſcope was about 10 feet, having a fine hair in its focus. The event of this accurate experiment was as follows:—

Having choſen a proper and very diſtinct erect object, whoſe diſtance was 2588 feet, June 15. O. S. 1708, in the morning, the barometer being then at 29.7$\frac{1}{2}$, and the thermometer at 60, they firſt exhauſted the priſm, and then applying it to the teleſcope, the horizontal hair in the focus covered a mark on the object diſtinctly ſeen through the vacuum, the two glaſſes being equally inclined to the viſual ray. Then admitting the air into the priſm, the object was ſeen to riſe above the hair gradually as the air entered, and in the end the hair was obſerved to hide a mark 10$\frac{1}{4}$ inches below the former mark. This they often repeated, and with the ſame ſucceſs.

After this they applied the condenſing engine to the priſm; and having forced in another atmoſphere, ſo that the denſity of the included air was double to that of the outward, they again placed it before the teleſcope, and, letting out the air, the object which before ſeemed to riſe, appeared gradually to deſcend, and the hair at length reſted on an object higher than before by the ſame interval of 10$\frac{1}{4}$ inches. This experiment they likewiſe frequently repeated without any variation in the event.

They then forced in another atmoſphere; and upon diſcharging the condenſed air, the object was ſeen near 21 inches lower than before.

Now the radius in this caſe being 2588 feet, 10$\frac{1}{4}$ inches will ſubtend an angle of one minute and 8 ſeconds, and the angle of incidence of the viſual ray being 32 degrees (becauſe the angle of the glaſs planes was 64), it follows from the known laws of refraction, that as the ſine of 39° is to that of 31° 59′ 26″, differing from 32° by 34″ the half of 1′ 8″; ſo is the ſine of any other incidence, to the ſine of its angle of refraction; and ſo is radius, or 1000000, to 999736; which, therefore, is the proportion between the ſine of incidence *in vacuo* and the ſine of refraction from thence into common air.

14 Refractive power of the air determined.

It appears, by theſe experiments, that the refractive power of the air is proportionable to its denſity. And ſince the denſity of the atmoſphere is as its weight directly, and its heat inverſely, the ratio of its denſity, at any given time, may be had by comparing the heights of the barometer and thermometer; and thence he concludes that this will alſo be the ratio of the refraction of the air. But Dr Smith obſerves, that, before we can depend upon the accuracy of this concluſion, we ought to examine whether heat and cold alone may not alter the refractive power of air, while its denſity continues the ſame. This, he ſays, may be tried, by heating the condenſed or rarefied air, ſhut up in the priſm, juſt before it is fixed to the teleſcope, and by obſerving whether the hair in its focus will continue to cover the ſame mark all the while that the air is cooling.

The French academicians, being informed of the reſult of the above-mentioned experiment, employed M. De l'Iſle the younger to repeat the former experiment with more care; and he preſently found, that their operators had never made any vacuum at all, there being chinks in their inſtrument, through which the air had inſinuated itſelf. He therefore annexed a gage to his inſtrument, by which means he was ſure of his vacuum; and then the reſult of the experiment was the ſame with that in England. The refraction was always in proportion to the denſity of the air, excepting when the mercury was very low, and conſequently the air very rare; in which caſe the whole quantity being very ſmall, he could not perceive much difference in them. Comparing, however, the refractive power of the atmoſphere, obſerved at Paris, with the reſult of his experiment, he found, that the beſt vacuum he could make was far ſhort of that of the etherial regions above the atmoſphere.

Dr Hooke firſt ſuggeſted the thought of making allowance for the effect of the refraction of light, in paſſing from the higher and rarer, to the lower and denſer regions of the atmoſphere, in the computed height of mountains. To this he aſcribes the different opinions of authors concerning the height of ſeveral very high hills. He could not account for the appearance of the Peak of Teneriffe, and ſeveral very high mountains, at ſo great a diſtance as that at which they are actually ſeen, but upon the ſuppoſition of the curvature of the viſual ray, that is made by its paſſing obliquely through a medium of ſuch different denſity, from the top of them to the eye, very far diſtant in the horizon. All calculations of the height of mountains that are made upon the ſuppoſition that the rays of light come from the tops of them, to our eyes, in ſtraight lines, muſt, he ſays, be very erroneous.

Dr Hooke gives a very good account of the twinkling of the ſtars; aſcribing it to the irregular and unequal refraction of the rays of light, which is alſo the reaſon why the limbs of the ſun, moon, and planets, appear to wave or dance. And that there is ſuch an unequal diſtribution of the parts of the atmoſphere, he ſays, is manifeſt from the different degrees of heat and cold in the air. This, he ſays, will be evident by looking upon diſtant objects, over a piece of hot glaſs, which cannot be ſuppoſed to throw out any kind of exhalation from itſelf, as well as through aſcending ſteams of water.

About this time Grimaldi firſt obſerved that the coloured image of the ſun refracted through a priſm is

15 Colours diſcovered to ariſe from refraction.

always oblong, and that colours proceed from refraction.—The way in which he firſt diſcovered this was by Vitellio's experiment above mentioned, in which a piece of white paper placed at the bottom of a glaſs veſſel filled with water, and expoſed to the light of the ſun, appears coloured. However, he obſerved, that in caſe the two ſurfaces of the refracting medium were exactly parallel to each other, no colours were produced. But of the true cauſe of thoſe colours, viz. the different refrangibility of the rays of light, he had not the leaſt ſuſpicion.

16 Different refrangibility of the rays of light diſcovered by Sir Iſaac Newton.

This diſcovery was reſerved for Sir Iſaac Newton, and which occurred to him in the year 1666. At that time he was buſied in grinding optic glaſſes, and procured a triangular glaſs priſm to ſatisfy himſelf concerning the phenomena of colours. While he amuſed himſelf with this, the oblong figure of the coloured ſpectrum firſt ſtruck him. He was ſurpriſed at the great diſproportion betwixt its length and breadth; the former being about five times the meaſure of the latter. He could hardly think that any difference in the thickneſs of the glaſs or in the compoſition of it, could have ſuch an influence on the light. However, without concluding any thing *à priori*, he proceeded to examine the effects of theſe circumſtances, and particularly tried what would be the conſequence of tranſmitting the light through parts of the glaſs that were of different thickneſſes, or through holes in the window-ſhutter of different ſizes; or by ſetting the priſm on the outſide of the ſhutter, that the light might paſs through it, and be refracted before it was terminated by the hole.

He then ſuſpected that theſe colours might ariſe from the light being dilated by ſome unevenneſs in the glaſs, or ſome other accidental irregularity; and to try this, he took another priſm like the former, and placed it in ſuch a manner, as that the light, paſſing through them both, might be refracted contrariwiſe, and ſo be returned by the latter into the ſame courſe from which it had been diverted by the former. In this manner he thought that the regular effects of the firſt priſm would be deſtroyed by the ſecond; but that the irregular ones would be augmented by the multiplicity of refractions. The event was, that the light, which by the firſt priſm was diffuſed into an oblong form, was by the ſecond reduced into a circular one, with as much regularity as if it had not paſſed through either of them.

At laſt, after various experiments and conjectures, he hit upon what he calls the *experimentum crucis*, and which completed this great diſcovery. He took two boards, and placed one of them cloſe behind the priſm at the windows, ſo that the light might paſs through a ſmall hole made in it for the purpoſe, and fall on the other board, which he placed at the diſtance of about twelve feet; having firſt made a ſmall hole in it alſo, for ſome of that incident light to paſs through. He then placed another priſm behind the ſecond board, ſo that the light which was tranſmitted through both the boards might paſs through that alſo, and be again refracted before it arrived at the wall.—This being done, he took the firſt priſm in his hand, and turned it about its axis, ſo much as to make the ſeveral parts of the image caſt on the ſecond board, ſucceſſively to paſs through the hole in it, that he might obſerve to what places on the wall the ſecond priſm would refract them; and he ſaw, by the change of thoſe places, that the light tending to that end of the image towards which the refraction of the firſt priſm was made, did, in the ſecond priſm, ſuffer a refraction conſiderably greater than the light which tended to the other end. The true cauſe, therefore, of the length of the image was diſcovered to be no other, than that light is not ſimilar, or homogeneal; but that it conſiſts of rays, ſome of which are more refrangible than others: ſo that, without any difference in their incidence on the ſame medium, ſome of them ſhall be more refracted than others; and therefore, that, according to their particular degrees of refrangibility, they will be tranſmitted through the priſm to different parts of the oppoſite wall.

Since it appears from theſe experiments that different rays of light have different degrees of refrangibility, it neceſſarily follows, that the rules laid down by preceding philoſophers concerning the refractive power of water, glaſs, &c. muſt be limited to the middle kind of rays. Sir Iſaac, however, proves that the ſine of the incidence of every kind of light, conſidered apart, is to its ſine of refraction in a given ratio. This he deduces, both by experiment, and alſo geometrically, from the ſuppoſition that bodies refract the light by acting upon its rays in lines perpendicular to their ſurfaces.

17 Mr Dollond's diſcovery of the method of correcting the faults in refracting teleſcopes.

The moſt important diſcovery with regard to refraction ſince the time of Sir Iſaac Newton is that of Mr Dollond, who found out a method of curing the faults of refracting teleſcopes ariſing from the different refrangibility of the rays, and which had been generally thought impoſſible to be removed. Notwithſtanding the great diſcovery of Sir Iſaac Newton concerning the different refrangibility of the rays of light, he had no idea but that they were all affected in the ſame proportion by every medium, ſo that the refrangibility of the extreme rays might be determined if that of the mean ones was given. From this it would follow, as Mr Dollond obſerves, that equal and contrary refractions muſt not only deſtroy each other, but that the divergency of the colours from one refraction would likewiſe be corrected by the other, and that there could be no poſſibility of producing any ſuch thing as refraction which would not be affected by the different refrangibility of light; or, in other words, that however a ray of light might be refracted backwards and forwards by different mediums, as water, glaſs, &c. provided it was ſo done, that the emergent ray ſhould be parallel to the incident one, it would ever after be white; and conſequently, if it ſhould come out inclined to the incident, it would diverge, and ever after be coloured; and from this it was natural to infer, that all ſpherical object glaſſes of teleſcopes muſt be equally affected by the different refrangibility of light, in proportion to their apertures, of whatever materials they may be formed.

For this reaſon, Sir Iſaac Newton, and all other philoſophers and opticians, had deſpaired of bringing refracting teleſcopes to any great degree of perfection, without making them of an immoderate and very inconvenient length. They therefore applied themſelves chiefly to the improvement of the reflecting teleſcope; and the buſineſs of refraction was dropped till about the year 1747, when M. Euler, improving upon a hint of Sir Iſaac Newton's, formed a ſcheme of making object glaſſes of two materials, of different refractive powers; hoping, that by this difference, the refractions would balance one another, and thereby prevent the diſperſion of the rays that is occaſioned by the difference of refrangibility. Theſe object glaſſes were compoſed of two lenſes of glaſs with water between them. This memoir of M. Euler excited the attention of Mr Dollond. He carefully went over all M. Euler's calculations, ſubſtituting for his hypothetical laws of refraction thoſe which had been actually aſcertained by the experiments of Newton; and found, that, after this neceſſary ſubſtitution, it followed from M. Euler's own principles, that there could be no union of the foci of all kinds of colours, but in a lens infinitely large.

M. Euler did not mean to controvert the experiments of Newton: but he ſaid, that they were not contrary to his hypotheſis, but in ſo ſmall a degree as might be neglected; and aſſerted, that, if they were admitted in all their extent, it would be impoſſible to correct the difference of refrangibility occaſioned by the tranſmiſſion of the rays from one medium into another of different denſity; a correction which he thought was very poſſible, ſince he ſuppoſed it to be actually effected in the ſtructure of the eye, which in his opinion was made to conſiſt of different mediums for that very purpoſe. To this kind of reaſoning Mr Dollond made no reply, but by appealing to the experiments of Newton, and the great circumſpection with which it was known that he conducted all his inquiries.

In this ſtate of the controverſy, the friends of M. Clairaut engaged him to attend to it; and it appeared to him, that, ſince the experiments of Newton cited by Mr Dollond could not be queſtioned, the ſpeculations of M. Euler were more ingenious than uſeful.

The ſame paper of M. Euler was alſo particularly noticed by M. Klingenſtierna of Sweden, who gave a conſiderable degree of attention to the ſubject, and diſcovered that, from Newton's own principles, the reſult of the 8th experiment of the ſecond book of his Optics could not anſwer his deſcription of it.

He found, he ſays, that when light goes out of air through ſeveral contiguous refracting mediums, as through water and glaſs, and thence goes out again into air, whether the refracting ſurfaces be parallel or inclined to one another, that light, as often as by contrary refractions it is ſo corrected as to emerge in lines parallel to thoſe in which it was incident, continues ever after to be white; but if the emergent rays be inclined to the incident, the whiteneſs of the emerging light will, by degrees, in paſſing on from the place of emergence, become tinged at its edges with colours. This he tried by refracting light with priſms of glaſs, placed within a priſmatic veſſel of water.

By theorems deduced from this experiment he infers, that the refractions of the rays of *every* ſort, made out of any medium into air, are known by having the refraction of the rays of *any one* ſort; and alſo that the refraction out of one medium into another is found as often as we have the refractions out of them both into any third medium.

On the contrary, the Swediſh philoſopher obſerves, that, in this experiment, the rays of light, after paſſing through the water and the glaſs, though they come out parallel to the incident rays, will be coloured; but that the ſmaller the glaſs priſm is, the nearer will the reſult of it approach to Newton's deſcription.

This paper of M. Klingenſtierna being communicated to Mr Dollond by M. Mallet, made him entertain doubts concerning Newton's report, and determined him to have recourſe to experiment.

He therefore cemented together two plates of parallel glaſs at their edges, ſo as to form a priſmatic veſſel, when ſtopped at the ends or baſes; and the edge being turned downwards, he placed in it a glaſs priſm, with one of its edges upwards, and filled up the vacancy with clear water; ſo that the refraction of the priſm was contrived to be contrary to that of the water, in order that a ray of light, tranſmitted through both theſe refracting mediums, might be affected by the difference only between the two refractions. As he found the water to refract more or leſs than the glaſs priſm, he diminiſhed or increaſed the angle between the glaſs plates, till he found the two contrary refractions to be equal; which he diſcovered by viewing an object through this double priſm. For when it appeared neither raiſed or depreſſed, he was ſatisfied that the refractions were equal, and that the emergent rays were parallel to the incident.

Now, according to the prevailing opinion, he obſerves, the object ſhould have appeared through this double priſm in its natural colour; for if the difference of refrangibility had been in all reſpects equal in the two equal refractions, they would have rectified each other. But this experiment fully proved the fallacy of the received opinion, by ſhowing the divergency of the light by the glaſs priſm to be almoſt double of that by the water; for the image of the object, though not at all refracted, was yet as much infected with priſmatic colours, as if it had been ſeen through a glaſs wedge only, whoſe refracting angle was near 30 degrees.

This experiment is the very ſame with that of Sir Iſaac Newton's above-mentioned, notwithſtanding the reſult was ſo remarkably different; but Mr Dollond aſſures us, that he uſed all poſſible precaution and care in his proceſs; and he kept his apparatus by him, that he might evince the truth of what he wrote, whenever he ſhould be properly required to do it.

He plainly ſaw, however, that if the refracting angle of the water veſſel could have admitted of a ſufficient increaſe, the divergency of the coloured rays would have been greatly diminiſhed, or entirely rectified; and that there would have been a very great refraction without colour, as he had already produced a great diſcolouring without refraction: but the inconveniency of ſo large an angle as that of the priſmatic veſſel muſt have been, to bring the light to an equal divergency with that of the glaſs priſm whoſe angle was about 60 degrees, made it neceſſary to try ſome experiments of the ſame kind with ſmaller angles.

Accordingly, he got a wedge of plate glaſs, the angle of which was only nine degrees; and uſing it in the ſame circumſtances, he increaſed the angle of the water wedge, in which it was placed, till the divergency of the light by the water was equal to that by the glaſs; that is, till the image of the object, though conſiderably refracted by the exceſs of the refraction of the water, appeared nevertheleſs quite free from any colours proceeding from the different refrangibility of the light; and as near as he could then meaſure, the refraction by the water was about $\frac{5}{6}$ of that by the glaſs. He acknowledges, indeed, that he was not very exact in taking the meaſures, becauſe his buſineſs was not at that time to determine the exact proportions, ſo much as to ſhow that the divergency of the colours, by different ſubſtances, was by no means in proportion to the refractions, and that there was a poſſibility of refraction without any divergency of the light at all.

As theſe experiments clearly proved, that different ſubſtances made the light to diverge very differently in proportion to their general refractive power, Mr Dollond began to ſuſpect that ſuch variety might poſſibly be found in different kinds of glaſs, eſpecially as experience had already ſhown that ſome of the kinds made much better object glaſſes in the uſual way than others; and as no ſatisfactory cauſe had been aſſigned for ſuch difference, he thought there was great reaſon to preſume that it might be owing to the different divergency of the light in the ſame refractions.

His next buſineſs, therefore, was to grind wedges of different kinds of glaſs, and apply them together; ſo that the refractions might be made in contrary directions, in order to diſcover, as in the above-mentioned experiments, whether the refraction and the divergency of the colours would vaniſh together. But a conſiderable time elapſed before he could ſet about that work: for though he was determined to try it at his leiſure, for ſatisfying his own curioſity, he did not expect to meet with a difference ſufficient to give room for any great improvement of teleſcopes, ſo that it was not till the latter end of the year 1757 that he undertook it; but his firſt trials convinced him that the buſineſs deſerved his utmoſt attention and application.

He diſcovered a difference far beyond his hopes in the refractive qualities of different kinds of glaſs, with reſpect to the divergency of colours. The yellow or ſtraw-coloured foreign ſort, commonly called *Venice glaſs*; and the *Engliſh crown glaſs*, proved to be very nearly alike in that reſpect; though, in general, the crown glaſs ſeemed to make the light diverge the leſs of the two. The common Engliſh plate glaſs made the light diverge more; and the white cryſtal, or Engliſh flint glaſs, moſt of all.

It was now his buſineſs to examine the particular qualities of every kind of glaſs that he could come at, not to amuſe himſelf with conjectures about the cauſe of this difference, but to fix upon two ſorts in which it ſhould be the greateſt; and he ſoon found theſe to be the crown glaſs and the white flint glaſs. He therefore ground one wedge of white flint, of about 25 degrees; and another of crown glaſs, of about 29 degrees: which refracted very nearly alike, but their power of making the colours diverge was very different. He then ground ſeveral others of crown glaſs to different angles, till he got one which was equal, with reſpect to the divergency of the light, to that in the white flint glaſs: for when they were put together, ſo as to refract in contrary directions, the refracted light was entirely free from colours. Then meaſuring the refraction of each wedge with theſe different angles, he found that of the white glaſs to be to that of the crown glaſs nearly as two to three: and this proportion held very nearly in all ſmall angles; ſo that any two wedges made in this proportion, and applied together, ſo as to refract in a contrary direction, would refract the light without any diſperſion of the rays.

In a letter to M. Klingenſtierna, quoted by M. Clairaut, Mr Dollond ſays, that the ſine of incidence in crown glaſs is to that of its general refraction as 1 to 1.53, and in flint glaſs as 1 to 1.583.

To apply this knowledge to practice, Mr Dollond went to work upon the object glaſſes of teleſcopes; not doubting but that, upon the ſame principles on which a refracted colourleſs ray was produced by priſms, it might be done by lenſes alſo, made of ſimilar materials. And he ſucceeded, by conſidering, that, in order to make two ſpherical glaſſes that ſhould refract the light in contrary directions, the one muſt be concave and the other convex; and as the rays are to converge to a real focus, the exceſs of refraction muſt evidently be in the convex lens. Alſo, as the convex glaſs is to refract the moſt, it appeared from his experiments, that it muſt be made of crown glaſs, and the concave of white flint glaſs. Farther, As the refractions of ſpherical glaſſes are in an inverſe ratio of their focal diſtances, it follows, that the focal diſtances of the two glaſſes ſhall be inverſely as the ratios of the refractions of the wedges; for being thus proportioned, every ray of light that paſſes through this combined glaſs, at whatever diſtance it may paſs from its axis, will conſtantly be refracted, by the difference between two contrary refractions, in the proportion required; and therefore the different refrangibility of the light will be entirely removed.

Notwithſtanding our author had theſe clear grounds in theory and experiment to go upon, he found that he had many difficulties to ſtruggle with when he came to reduce them into actual practice; but with great patience and addreſs, he at length got into a ready method of making teleſcopes upon theſe new principles.

His principal difficulties aroſe from the following circumſtances. In the firſt place, The focal diſtances, as well as the particular ſurfaces, muſt be very nicely proportioned to the denſities or refracting powers of the glaſſes, which are very apt to vary in the ſame ſort of glaſs made at different times. Secondly, The centres of the two glaſſes muſt be placed truly in the common axis of the teleſcope, otherwiſe the deſired effect will be in a great meaſure deſtroyed. Add to theſe, that there are four ſurfaces to be wrought perfectly ſpherical; and any perſon, he ſays, but moderately practiſed in optical operations, will allow, that there muſt be the greateſt accuracy throughout the whole work. At length, however, after numerous trials, and a reſolute perſeverance, he was able to conſtruct refracting teleſcopes, with ſuch apertures and magnifying powers, under limited lengths, as, in the opinion of the beſt judges, far exceeded any thing that had been produced before, repreſenting objects with great diſtinctneſs, and in their true colours.

It was objected to Mr Dollond's diſcovery, that the ſmall diſperſion of the rays in crown glaſs is only apparent, owing to the opacity of that kind of glaſs, which does not tranſmit the fainter coloured rays in a ſufficient quantity; but this objection is particularly conſidered, and anſwered by M. Beguelin.

As Mr Dollond did not explain the methods which he took in the choice of different ſpheres proper to deſtroy the effect of the different refrangibility of the rays of light, and gave no hint that he himſelf had any rule to direct himſelf in it; and as the calculation of the diſperſion of the rays, in ſo complicated an affair, is very delicate; M. Clairaut, who had given a good deal of attention to this ſubject, from the beginning of the controverſy, endeavoured to make out a complete theory of it.

Without ſome aſſiſtance of this kind, it is impoſſible, ſays this author, to conſtruct teleſcopes of equal goodneſs with thoſe of Mr Dollond, except by a ſervile imitation of his; which, however, on many accounts, would be very unlikely to anſwer. Beſides, Mr Dollond only gave his proportions in general, and pretty near the truth; whereas the greateſt poſſible preciſion is neceſſary. Alſo the beſt of Mr Dollond's teleſcopes were far ſhort of the Newtonian ones (A); whereas it might be expected that they ſhould exceed them, if the foci of all the coloured rays could be as perfectly united after refraction through glaſs, as after reflection from a mirror; ſince there is more light loſt in the latter caſe than in the former.

With a view, therefore, to aſſiſt the artiſt, he endeavoured to aſcertain the refractive power of different kinds of glaſs, and alſo their property of ſeparating the rays of light by the following exact methods. He made uſe of two priſms placed cloſe to one another, as Mr Dollond had done: but, inſtead of looking through them, he placed them in a darkened room; and when the image of the ſun, tranſmitted through them, was perfectly white, he concluded that the different refrangibility of the rays was corrected.

In order to aſcertain with more eaſe the true angles that priſms ought to have to deſtroy the effect of the difference of refrangibility, he conſtructed one which had one of its ſurfaces cylindrical, with ſeveral degrees of amplitude. By this means, without changing his priſms, he had the choice of an infinity of angles; among which, by examining the point of the curve ſurface which receiving the ſolar ray, gave a white image, he could eaſily find the true one.

He alſo aſcertained the proportion in which different kinds of glaſs ſeparated the rays of light, by meaſuring, with proper precautions, the oblong image of the ſun made by tranſmitting a beam of light through them. In making theſe experiments, he hit upon an eaſy method of convincing any perſon of the greater refractive power of Engliſh flint glaſs above the common French glaſs, both with reſpect to the mean refraction, and the different refrangibility of the colours; for having taken two priſms, of theſe two kinds of glaſs, but equal in all other reſpects, and placed them ſo that they received, at the ſame time, two rays of the ſun, with the ſame degree of incidence, he ſaw, that of the two images, that which was produced by the Engliſh flint glaſs was a little higher up on the wall than the other, and longer by more than one half.

M. Clairaut was aſſiſted in theſe experiments by M. De Tournieres, and the reſults agreed with Mr Dollond's in general; but whereas Mr Dollond had made the diſperſion of the rays in glaſs and in water to be as five to four (acknowledging, however, that he did not pretend to do it with exactneſs), theſe gentlemen, who took more pains, and uſed more precautions, found it to be as three to two. For the theorems and problems deduced by M. Clairaut from theſe new principles of optics, with a view to the perfection of teleſcopes, we muſt refer the reader to *Mem. Acad. Par.* 1756, 1757.

The labours of M. Clairaut were ſucceeded by thoſe of M. D'Alembert, which ſeem to have given the makers of theſe achromatic teleſcopes all the aid that calculations can afford them. This excellent mathematician has likewiſe propoſed a variety of new conſtructions of theſe teleſcopes, the advantages and diſadvantages of which he diſtinctly notes; at the ſame time that he points out ſeveral methods of correcting the errors to which they are liable: as by placing the object glaſſes, in ſome caſes, at a ſmall diſtance from one another, and ſometimes by uſing eye glaſſes of different refractive powers; which is an expedient that ſeems not to have occured to any perſon before him. He even ſhows, that teleſcopes may be made to advantage, conſiſting of only one object glaſs, and an eye glaſs of a different refractive power. Some of his conſtructions have two or more eye glaſſes of different kinds of glaſs. This ſubject he conſidered at large in one of the volumes of his *Opuſcules Mathematiques*. We have alſo three memoirs of M. D'Alembert upon this ſubject, among thoſe of the French Academy; one in the year 1764, another in 1765, and a third in 1767.

At the concluſion of his ſecond memoir he ſays, that he does not doubt, but, by the different methods he propoſes, achromatic teleſcopes may be made to far greater degrees of perfection than any that have been ſeen hitherto, and even ſuch as is hardly credible: And though the crown glaſs, by its greeniſh colour, may abſorb ſome part of the red or violet rays, which, however, is not found to be the caſe in fact; that objection cannot be made to the common French glaſs, which is white, and which on this account he thinks muſt be preferable to the Engliſh crown glaſs.

Notwithſtanding Meſſrs Clairaut and D'Alembert ſeemed to have exhauſted the buſineſs of calculation on the ſubject of Mr Dollond's teleſcopes, no uſe could be made of their labours by foreign artiſts. For ſtill the teleſcopes made in England, according to no exact

---

(A) This aſſertion of M. Clairaut might be true at the time that it was made, but it is by no means ſo at preſent.

rule, as foreigners ſuppoſed, were greatly ſuperior to any that could be made elſewhere, though under the immediate direction of thoſe able calculators. For this M. Beguelin aſſigned ſeveral reaſons. Among others, he thought that their geometrical theorems were too general, and their calculations too complicated, for the uſe of workmen. He alſo thought, that in conſequence of neglecting ſmall quantities, which theſe calculators profeſſedly did, in order to make their algebraical expreſſions more commodious, their concluſions were not ſufficiently exact. But what he thought to be of the moſt conſequence, was the want of an exact method of meaſuring the refractive and diſperſing powers of the different kinds of glaſs; and for want of this, the greateſt preciſion in calculation was altogether uſeleſs.

Theſe conſiderations induced this gentleman to take another view of this ſubject; but ſtill he could not reconcile the actual effect of Mr Dollond's teleſcopes with his own concluſions: ſo that he imagined, either that he had not the true refraction and diſperſion of the two kinds of glaſs given him; or elſe, that the aberration which ſtill remained after his calculations, muſt have been deſtroyed by ſome irregularity in the ſurfaces of the lenſes. He finds ſeveral errors in the calculations both of M. D'Alembert and Clairaut, and concludes with expreſſing his deſign to purſue this ſubject much farther.

M. Euler, who firſt gave occaſion to this inquiry, which terminated ſo happily for the advancement of ſcience, being perſuaded both by his reaſoning and calculations, that Mr Dollond had diſcovered no new principle in optics, and yet not being able to controvert Mr Short's teſtimony in favour of the goodneſs of his teleſcopes, concluded that this extraordinary effect was owing, in part, to the crown glaſs not tranſmitting all the red light, which would otherwiſe have come to a different focus, and have diſtorted the image; but principally to his happening to hit on a juſt curvature of his glaſs, which he did not doubt would have produced the ſame effect if his lenſes had all been made of the ſame kind of glaſs. In another place he imagines that the goodneſs of Mr Dollond's teleſcope might be owing to the eye glaſs. If my theory, ſays he, be true, this diſagreeable conſequence follows, that Mr Dollond's object glaſſes cannot be exempt from the diſperſion of colours: yet a regard to ſo reſpectable a teſtimony embarraſſes me extremely, it being as difficult to queſtion ſuch expreſs authority, as to abandon a theory which appears to me perfectly well founded, and to embrace an opinion, which is as contrary to all the eſtabliſhed laws of nature as it is ſtrange and ſeemingly abſurd. He even appeals to experiments made in a darkened room; in which, he ſays, he is confident that Mr Dollond's object-glaſſes would appear to have the ſame defects that others are ſubject to.

Not doubting, however, but that Mr Dollond, either by chance, or otherwiſe, had made ſome conſiderable improvement in the conſtruction of teleſcopes, by the combination of glaſſes, he abandoned his former project, in which he had recourſe to different mediums, and confined his attention to the correction of the errors which ariſe from the curvature of lenſes. But while he was proceeding, as he imagined, upon the true principles of optics, of which, however, he made but little uſe, he could not help expreſſing his ſurpriſe that Mr Dollond ſhould have been led to ſo important a diſcovery by reaſoning in a manner quite contrary to the nature of things. At length, however, M. Euler was convinced of the reality and importance of Mr Dollond's diſcoveries; and very frankly acknowledges, that he ſhould perhaps never have been brought to aſſent to it, had not his friend M. Clairaut aſſured him that the experiments of the Engliſh optician might be depended upon. However, the experiments of M. Zeiher of Peterſburgh gave him the moſt complete ſatiſfaction with reſpect to this new law of refraction.

This gentleman demonſtrated, that it is the lead in the compoſition of glaſs that gives it this remakable property, that while the refraction of the mean rays is nearly the ſame, that of the extremes differs conſiderably. And, by increaſing the quantity of lead in the mixture, he produced a kind of glaſs, which occaſioned a much greater ſeparation of the extreme rays than the flint glaſs which Mr Dollond had made uſe of. By this evidence M. Euler owns that he was compelled to renounce the principle which, before this time, had been conſidered as inconteſtable, *viz.* that the diſperſion of the extreme rays depends upon the refraction of the mean: and that the former varies with the quality of the glaſs, while the latter is not affected by it.

From theſe new principles M. Euler deduces theorems concerning the combination of the lenſes, and, in a manner ſimilar to M. Clairaut and D'Alembert, points out methods of conſtructing achromatic teleſcopes.

18 Different compoſitions of glaſs for the purpoſe of correcting the faults of refracting teleſcopes.

While he was employed upon this ſubject, he informs us, that he received a letter from M. Zeiher, dated Peterſburgh 30th of January 1764, in which he gives him a particular account of the ſucceſs of his experiments on the compoſition of glaſs; and that, having mixed minium and ſand in different proportions, the reſult of the mean refraction and the diſperſion of the rays varied according to the following table.

Proportion of minium to flint.	Mean refraction from air into glaſs.	Diſperſion of the rays in compariſon of crown glaſs.
I. — 3 : 1	2028 : 1000	4800 : 1000
II. — 2 : 1	1830 : 1000	3550 : 1000
III. — 1 : 1	1787 : 1000	3259 : 1000
IV. — $\frac{3}{4}$: 1	1732 : 1000	2207 : 1000
V. — $\frac{1}{2}$: 1	1724 : 1000	1800 : 1000
VI. — $\frac{1}{4}$: 1	1664 : 1000	1354 : 1000

By this table it is evident, that a greater quantity of lead not only occaſions a greater diſperſion of the rays, but alſo conſiderably increaſes the mean refraction. The firſt of theſe kinds of glaſs, which contains three times as much minium as flint, will appear very extraordinary; ſince, hitherto, no tranſparent ſubſtance has been known, whoſe refractive power exceeded the ratio of two to one, and that the diſperſion occaſioned by this glaſs is almoſt five times as great as that of crown claſs, which could not be believed by thoſe who entertained

Ombre

Omelet.

called *beaſts*. And if the ombre wins all the nine tricks, it is called *winning the vole*.

In ombre by five, which many, on account of its not requiring ſo cloſe an attention, prefer to that by three, only eight cards a-piece are dealt; and five tricks muſt be won, otherwiſe the ombre is beaſted. Here the perſon who undertakes the game, after naming the trump, calls a king to his aſſiſtance; upon which the perſon in whoſe hand the king is, without diſcovering himſelf, is to aſſiſt him as a partner, and to ſhare his fate. If, between both, they can make five tricks, the ombre wins two counters, and the auxiliary king only one; but when the counters are even, they divide them equally. If the ombre venture the game without calling in any king, this too is called *playing ſans prendre;* in which caſe the other four are all againſt him, and he muſt win five tricks alone, or be beaſted. The reſt is much the ſame as by three.

Ombre de ſoleil, "Shadow of the ſun," in heraldry, is when the ſun is borne in armory, ſo as that the eyes, noſe, and mouth, which at other times are repreſented, do not appear; and the colouring is thin, ſo that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called *Spoletto* and *Perugia*.

OMBRO, or Lombro, a town of Italy, in the duchy of Tuſcany, and territory of the Siennois, ſituated near the Tuſcan ſea, a little ſouth of the lake of Caſtiglione, 45 miles ſouth-weſt of Sienna.

OMBROMETER, a machine to meaſure the quantity of rain that falls. We have the deſcription and ſign of one in Phil. Tranſ. N° 473. p. 12. It conſiſts of a tin funnel, whoſe ſurface is an inch ſquare, with a flat board, and a glaſs tube ſet into the middle of it in a groove. The riſe of the water in the tube, whoſe capacity at different times muſt be meaſured and marked, ſhows the quantity of rain that has fallen.

OMELET, or Amlet, a kind of pancake or fricaſſee of eggs, with other ingredients, very uſual in Spain and France. It may be made as follows: The eggs being beaten, are to be ſeaſoned with ſalt and pepper, and then fried in butter made boiling hot; this done, gravy is to be poured on, and the whole ſtewed with chives and parſley ſhred ſmall: when one ſide is fried enough, it is to be turned on the other.

Omen.

OMEN, is a word which, in its proper ſenſe, ſignifies a ſign or indication of ſome future event taken from the language of a perſon ſpeaking without any intent to prophecy. Hence Tully ſays, "Pythagorei non ſolum voces deorum obſervarunt, ſed etiam hominum, quæ vocent *omina;*" "the Pythagoreans attend to the diſcourſe not only of gods, but alſo of men, which they call *omens*." This ſort of omen was ſuppoſed to depend much upon the will of the perſon concerned in the event; whence the phraſes *accepit omen, arripuit omen*. Such were the original *omens;* but they were afterwards derived from *things* as well as from words. Thus Paterculus, ſpeaking of the head of Sulpicius on the roſtrum, ſays it was *velut omen imminentis proſcriptionis*, "the omen of an impending proſcription." Suetonius ſays of Auguſtus, that he believed implicitly in certain omens; and that, *ſi manè ſibi calceus perperam, ac ſiniſter pro dextero induceretur, ut dirum*, "if his ſhoes were improperly put on in the morning, eſpecially if the left ſhoe was put upon his right foot, he held it for a bad omen." Omen was uſed in a ſtill larger ſenſe, to ſignify an *augury;* as in the following line of Tully: "Sic aquilæ clarum firmavit Jupiter *omen;*" "thus Jove confirmed the bright omen of the eagle." It was laſtly uſed, in the moſt generic ſenſe of all, for a portent or prodigy; as in the third book of the Æneid, where a myrtle torn up by Æneas dropped blood. Upon this appearance, ſays the hero,

> Mihi frigidus horror
> Membra quatit, gelidusque coit formidine ſanguis.

And the ſame thing being repeated upon his breaking a branch from another tree, he prayed to the gods to avert the *omen*.

> Multa movens animo Nymphas venerabar agreſtes,
> Gradivumque patrem, Geticis qui præſidet arvis,
> Rite ſecundarent viſus, *omen*que levarent (A).

Theſe portentous or ſupernatural omens were either external or internal. Of the former ſort were thoſe ſhowers of blood ſo frequently occurring in the Roman hiſtory, which were much of the ſame nature with this adventure of Æneas, which he calls monstra deum. Of the ſecond ſort were thoſe ſudden conſternations, which, ſeizing upon men without any viſible cauſe, were imputed to the agency of the god *Pan*, and hence called *panic fears*. But indeed there was hardly

---

(A) Inſtead of tranſlating theſe ſhort quotations, we ſhall here give Dryden's verſion of the whole of this portentous adventure, as we are perſuaded that the mere Engliſh reader, who alone can wiſh for a tranſlation, will be glad to have the fulleſt account of the bleeding myrtle, together with its effects on the mind of the hero. It is as follows:

> Not far, a riſing hillock ſtood in view;
> Sharp myrtles on the ſides and corners grew.
> There, while I went to crop the ſylvan ſcenes,
> And ſhade our altar with their leafy greens,
> I pull'd a plant (with horror I relate
> A prodigy ſo ſtrange, and full of fate):
> The rooted fibres roſe; and from the wound
> Black bloody drops diſtill'd upon the ground.
> Mute and amaz'd, my hair with terror ſtood;
> Fear ſhrunk my ſinews, and congeal'd my blood.
> Mann'd once again, another plant I try;
> That other guſh'd with the ſame ſanguine dye.
> Then, fearing guilt for ſome offence unknown,
> With prayers and vows the Dryads I atone,
> With all the ſiſters of the woods, and moſt
> The God of arms, who rules the Thracian coaſt:
> That they, or he, theſe omens would avert,
> Releaſe our fears, and better ſigns impart.

hardly any thing, however trivial from which the ancients did not draw omens. That it ſhould have been thought a direful omen when any thing befel the temples, altars, or ſtatues of the GODS, need excite no wonder; but that the meeting of a eunuch, a negro, a bitch with whelps, or a ſnake lying in the road, ſhould have been looked upon as portending bad fortune, is a deplorable inſtance of human weakneſs, and of the pernicious influence of ſuperſtition on the mind.

It is more than probable that this practice of making ordinary events ominous of good or bad fortune took its riſe in Egypt, the parent country of almoſt every ſuperſtition of paganiſm; but wherever it may have ariſen, it ſpread itſelf over the whole inhabited globe, and at this day prevails in a greater or leſs degree among the vulgar of all nations.

In England, is is reckoned a good omen, or a ſign of future happineſs, if the ſun ſhines on a couple coming out of the church after having been married. It is alſo eſteemed a good ſign if it rains whilſt a corpſe is burying:

> Happy is the bride that the ſun ſhines on;
> Happy is the corpſe that the rain rains on.

To break a looking glaſs is extremely unlucky; the party to whom it belongs will loſe his beſt friend.

If, going a journey on buſineſs, a ſow croſs the road, you will probably meet with a diſappointment, if not a bodily accident, before you return home. To avert this, you muſt endeavour to prevent her croſſing you; and if that cannot be done, you muſt ride round on freſh ground. If the ſow is attended with her litter of pigs, it is lucky, and denotes a ſucceſsful journey.

It is unlucky to ſee firſt one magpye, and then more; but to ſee two, denotes marriage or merriment; three, a ſucceſsful journey; four an unexpected piece of good news; five, you will ſhortly be in a great company. To kill a magpye, will certainly be puniſhed with ſome terrible misfortune.

If, in a family, the youngeſt daughter ſhould be married before her elder ſiſters, they muſt all dance at her wedding without ſhoes: this will counteract their ill luck, and procure them huſbands.

If you meet a funeral proceſſion, or one paſſes by you, always take off your hat: this keeps all evil ſpirits attending the body in good humour.

If, in eating, you miſs your mouth, and the victuals fall, it is very unlucky, and denotes approaching ſickneſs.

It is lucky to put on a ſtocking the wrong ſide outwards: changing it alters the luck.

When a perſon goes out to tranſact any important buſineſs, it is lucky to throw an old ſhoe after him.

It is unlucky to preſent a knife, ſciſſars, razor, or any ſharp or cutting inſtrument, to one's miſtreſs or friend, as they are apt to cut love and friendſhip. To avoid the ill effects of this, a pin, a farthing, or ſome trifling recompenſe, muſt be taken. To find a knife or razor, denotes ill luck and diſappointment to the party.

In the Highlands of Scotland, it is thought unlucky if a perſon ſetting out upon a journey ſtumble over the threſhold, or be obliged to return for any thing forgotten. If a ſportſman ſee any perſon ſtepping over his gun or fiſhing rod, he expects but little ſucceſs in that day's diverſion. *Sneezing* is alſo deemed ominous. If one ſneeze when making a bed, a little of the ſtraw or heath is taken out and thrown into the fire, that nothing may diſturb the reſt of the perſon who is to ſleep in the bed. Among the ſame people, ſucceſs in any enterpriſe is believed to depend greatly upon the firſt creature that preſents itſelf after the enterpriſe is undertaken. Thus, upon going to ſhoot, it is reckoned lucky to meet a horſe, but very unfortunate to ſee a hare, if ſhe eſcape; and upon meeting any creature deemed unlucky, the beſt means of averting the omen is to roll a ſtone towards it. The Greeks attributed the ſame efficacy to the rolling of a ſtone, though they greatly preferred *killing* the ominous animal, that the evil portended might fall on its own head *.

The motions and appearances of the clouds were not long ago conſidered as certain ſigns by which the ſkilful Highlander might attain to the knowledge of futurity. On the evening before *new year's day*, if a black cloud appeared in any part of the horizon, it was thought to prognoſticate a plague, a famine, or the death of ſome great man in that part of the country over which it ſhould appear to ſet; and in order to aſcertain the place threatened by the omen, the motions of this cloud were often watched through the whole night, if it happened to continue ſo long viſible above the horizon.

By the believers in this ſuperſtition there are days, as well as words and events, which are deemed ominous of good or bad fortune. The firſt day of every quarter, midſummer, and new year's day, are reckoned the moſt fortunate days in the year for accompliſhing any deſign. In the Iſle of Mull, ploughing, ſowing, and reaping, are always begun on *Tueſday*, though the moſt favourable weather for theſe purpoſes be in this way frequently loſt. That day of the week on which the third of May falls, is deemed unlucky throughout the whole year. In Morven, none will upon any account dig peat or turf for fuel on *Friday*; and it is reckoned unlucky to number the people or cattle belonging to any family, and doubly ſo if the number be taken on Friday. The age of the moon is alſo much attended to by the vulgar Highlanders. It it alleged, that during the increaſe things have a tendency to grow and ſtick together: and hence, in the Iſle of Sky, fences, which are there made of turf, are built only at that time; whilſt turf or peat for fuel are never, even in the moſt favourable weather, either made or ſtacked up but while the moon is in its wane. An opinion prevails in ſome places, that if a houſe take fire during the increaſe of the moon, the family to which it belongs will proſper in the world: but that if the fire happen while the moon is in the decreaſe, the family will from that time decline in its circumſtances, and ſink into poverty.

In attributing ſuch influence to the moon, the ſuperſtitious Highlanders have the honour to agree with the philoſophic Virgil, who in his Georgics gives the following ſage inſtructions to the huſbandman:

---

* See *Potter's Antiquities*, Vol. I. p. 346.

Ipſa dies alios alio dedit ordine Luna
Felices, operum. Quintam fuge:

* * * *

Septima poſt decimam felix et ponere vitem,
Et prenſos domitare boves, et licia telæ
Addere: nona fugæ melior, contraria furtis.

The lucky days in each revolving moon
For labour chooſe: the *fifth* be ſure to ſhun.

* * * *

The *ſeventh* is next the *tenth*, the beſt to join
Young oxen to the yoke, and plant the vine.
Then weavers ſtretch your ſtays upon the weft:
The *ninth* is good for travel, bad for theft.

Dryden.

From this coincidence of the ſuperſtition of the Roman poet with that of the natives of Mull and Morven, we are ſtrongly inclined to adopt the hypotheſis of the gentleman who favoured us with this accurate account of Highland omens. He juſtly obſerves, that this ſuperſtitious practice of auguring good or ill from trifling events, and from the particular phaſes of the moon, has no connexion whatever with popiſh prieſtcraft: he ſhows that the Romiſh clergy, even in the darkeſt age, were at pains to eradicate it as idle and impious; and he therefore infers, that it muſt be a relick of Druidiſm handed down by tradition from an era prior to the introduction of Chriſtianity into the Highlands and iſles of Scotland. That the Druids were acquainted with the particular doctrines of Pythagoras has been ſhown elſewhere (ſee Druids); that Virgil was no ſtranger to the Pythagorean philoſophy is known to every ſcholar; that Pythagoras and his followers were addicted to the dotages of Magic has been made apparent in that article; and therefore it appears to us probable at leaſt, that the attention paid to pretended omens, not only in the Highlands, but alſo in the low country of Scotland, and indeed among the vulgar in every country of Europe, is a remnant of one of the many ſuperſtitions which the Druids impoſed upon their deluded followers. That it is contrary to every principle of ſound philoſophy, all philoſophers will readily acknowledge; and whoever has ſtudied the writings of St Paul muſt be convinced that it is inconſiſtent with the ſpirit of genuine Chriſtianity.

OMENTUM, or [illegible], the *Cawl*, in anatomy, a membranaceous part, uſually furniſhed with a large quantity of fat; being placed under the peritonæum, and immediately above the inteſtines. See Anatomy, N° 90.

OMER, in Jewiſh antiquity. See Corus.

St OMER's, a ſtrong, fortified, large, and populous town of France, in Artois, and capital of a conſiderable bailiwick, with a caſtle and a biſhop's ſee. It is a fortreſs of conſiderable importance, and ſurrounded on one ſide with a large moraſs; and about it there are many ſluices, which ſerve to carry the water off when it is overflowed; and in the midſt of the moraſs there is a ſort of floating iſlands covered with verdure and trees. The cathedral is a handſome ſtructure; and there are other fine buildings, with a rich Benedictine abbey. The French became maſters of this place in 1679. It is ſeated on the river Aa, and on the ſide of a hill, eight miles north-weſt of Aire, and 135 north of Paris. E. Long. 2. 20. N. Lat. 54. 45.

OMOA, a Spaniſh town and fortification on the ſouth ſide of the bay of Honduras, N. Lat. 15. 50. W. Long. 89. 50. from London. It is the key to the bay; and ſuch is the depth of the water, that ſhips of any burden may ride in the harbour with ſafety. It is a place of the utmoſt importance to Spain, as the regiſter ſhips to and from Guatimala are ſent to it in the time of war. The town was firſt eſtabliſhed in 1751, under the command of Don Joſeph Antonio de Palmo. At that period the inhabitants were about 20 white men, 60 mulattoes and free negroes, and 200 ſlaves to the king of Spain; and the military force conſiſted of about 30 ſoldiers, beſides officers. The fort was originally compoſed of ſand confined in boarded coffers, and faced with half-burnt bricks. It was defended by 12 fine braſs 24 pounders mounted, four or five iron guns of different bores, and ſome field-pieces. The Spaniards, ſenſible of the importance of the place, afterwards fortified it at an incredible expence, the ſtone of which the walls are built having been raiſed from the ſea, and brought from the diſtance of 20 leagues. The outworks were not completely finiſhed in the year 1779, though 1000 men had then been employed upon them for 20 years.

Towards the end of that year an expedition was undertaken againſt this fortreſs, in conſequence of one formed by the Spaniards againſt the Britiſh logwood cutters in the bay of Honduras and on the Moſquito ſhore. The latter, finding themſelves hard preſſed by their enemies, applied to General Dulling governor of Jamaica for aſſiſtance; who accordingly ſent a detachment to their relief under Captain Dalrymple, with neceſſary ſupplies of arms, ammunition, and artillery. Before their arrival, however, the Spaniards had taken poſſeſſion of St George's Key, the chief ſettlement of the Britiſh in theſe parts, which they plundered, and took a number of priſoners; but thoſe who eſcaped, being joined by a body of their countrymen, retook it, and forced the enemy to retire. In the mean time Captain Dalrymple, who had been informed of the loſs of the place, was haſtening to the relief of the inhabitants, and in his way fell in with Admiral Parker, who was in queſt of ſome regiſter ſhips; but which, retreating into the harbour of Omoa, were too ſtrongly protected by the fort there to be attacked by ſea. As the Spaniards, however, had now been compelled to abandon St George's Key, it was propoſed to unite the Britiſh forces by ſea and land, and to attempt the conqueſt of this fortreſs. As the force under Captain Dalrymple was too inconſiderable to attempt the fort by land, it was augmented by the marines of the ſquadron and a ſtrong party of the ſettlers; though, after all, it did not exceed the number of the garriſon who oppoſed them.

The troops were landed at about nine miles diſtance from the fort in the duſk of the evening, with a deſign to march directly forward, in order to ſurpriſe and carry it by eſcalade in the night-time. No roads, however, being found, they were obliged to explore their way through narrow foot-paths, moraſſes, and over mountains ſo beſet with precipices, that they were obliged, in order to avoid them, to make uſe of

Omoa.

lights made of the cabbage tree In conſequence of theſe impediments they were yet at a conſiderable diſtance from the fort, when the approach of day diſcovered them to the enemy. An engagement enſued, in which the Spaniards were quickly routed and driven into the town: from whence as they continued to fire upon the Britiſh, it was found neceſſary to ſet fire to it, though very much againſt the inclination of the aſſailants.

In the mean time the ſquadron took the opportunity, while the town was in flames, to come into the bay, and approach the fort with an intention to batter it; but the garriſon returned their fire ſo briſkly, that no impreſſion could be made by that of the ſquadron, which was detained by want of wind from approaching ſufficiently near. The troops then, being maſters of the ground adjacent to the fort, erected ſeveral batteries in ſuch ſituations as were moſt proper for annoying it; but though they carried on their operations with great vigour, it was ſtill found that heavier artillery than any they poſſeſſed would be requiſite, the walls being no leſs than 18 feet in thickneſs; in conſequence of which they reſolved ſtill to attempt the place by eſcalade.

The attempt was made on the 21ſt of October, early in the morning. The troops entered the ditch, which fortunately for them happened to be dry, and fixed their ſcaling ladders againſt the walls, which were near 30 feet high. Two ſeamen mounted firſt; and, with admirable courage and preſence of mind, ſtood by the ladder which they had mounted, to guard it till others aſcended; and boldly preſented their pieces againſt a large party drawn up to receive them, though they prudently retained their fire till their comrades came up.

The ſquadron, now drawing near, kept up a heavy and continual fire upon the fort, while the Spaniards were ſtruck with ſuch ſurpriſe at the exceſſive celerity and boldneſs of the aſſailants, that they remained motionleſs and unable to oppoſe their enemies, notwithſtanding the exhortation and example of their officers. From this panic they never recovered; and while the ſeamen and ſoldiers continued to ſcale the walls with amazing quickneſs, the Spaniards never made any effort to defend themſelves. About 100 of them eſcaped over the walls on the oppoſite ſide of the fort; the remainder ſurrendered at diſcretion.

The whole of this tranſaction reflected the higheſt luſtre both on the conduct and courage of the Britiſh; and an inſtance of heroiſm is related in a Britiſh ſailor to which hiſtory affords nothing ſuperior. This man, having ſcaled the walls, had armed himſelf with a cutlaſs in each hand. Thus armed, he met with a Spaniſh officer unarmed, and juſt rouſed from ſleep. The generous tar ſcorned to take advantage of his condition, and therefore preſented him with one of his own cutlaſſes, ſaying, "You are now on a footing with me!" The officer, however, was too much ſtruck with admiration at his conduct to accept the offer, and took care to make the circumſtance ſufficiently known.—The value of the booty taken on this occaſion amounted to three millions of dollars; but the loſs moſt ſenſibly felt by the Spaniards was that of 250 quintals of quickſilver, a commodity indiſpenſably neceſſary in extracting the precious metals from their ores. They offered therefore to ranſom it at any price; but though the retention of it was far from affording a profit equal to that offered by the Spaniards, the Britiſh commanders abſolutely refuſed to part with it, on account of the advantages the enemy would derive from having the metal in their poſſeſſion. For the ſame reaſon they refuſed to accept of any ranſom for the fort, though the governor offered to lay down 300,000 dollars for it. The Spaniſh military and the inhabitants were treated with the utmoſt humanity; their perſonal effects remaining untouched: and this generoſity muſt have appeared to greater advantage, when contraſted with the behaviour of their own countrymen at Honduras, where the Britiſh were treated with remarkable ſeverity. The church plate and ornaments were reſtored, on condition that the terms of capitulation ſhould be faithfully kept.

Omoa, Omophagia.

In a ſhort time, however, it appeared that it would have been better to have accepted of a ranſom for the fort, as from circumſtances at that time it could not be retained in the poſſeſſion of Britain. A garriſon was indeed left for its defence on the departure of the Britiſh ſquadron; but as it was very inconſiderable, on account of the ſmall number of men that could be ſpared, the Spaniards quickly determined to make an attempt to regain the fort. For this purpoſe a body of 2000 men were collected, who inveſted it on the 25th of November. The Britiſh defended it with the utmoſt bravery; keeping up a conſtant fire on the enemy, and obliging them to retire for ſhelter, and take up their quarters behind a hill. Here they made preparations for an aſſault, in which their numbers left the ſucceſs, as they ſuppoſed, by no means dubious. The garriſon was therefore ſummoned to ſurrender, with a promiſe of the honours of war and a ſafe conveyance to Great Britain, denouncing at the ſame time the utmoſt vengeance in caſe of a refuſal; which being refuſed, the neceſſary preparations were made for an eſcalade.

The condition of the garriſon was now ſuch as could afford very little hope of being able to make any effectual reſiſtance. They were but 85 in number, moſt of whom were become incapable of duty either from illneſs or exceſſive fatigue. They were now alſo obliged to make one centinel anſwer for five, by ſhifting his place, and challenging as many times. There was no ſurgeon to attend the ſick and wounded; nor had they even any water but what came from a ſloop of war that lay abreaſt of the fort. In this deſperate ſituation, they reſolved, notwithſtanding the menances of the Spaniſh commander to render the place as unſerviceable as they could. For this purpoſe they ſpiked up all the guns; deſtroying the ſtores and ammunition that could not be carried off: they even locked the gates of the fort, after which they embarked without the loſs of a ſingle man. All this was performed in defiance of the large force that beſieged them; and the exploit, when duly conſidered, muſt appear not leſs a matter of aſtoniſhment than the extraordinary manner in which the fort had been taken. The officer who commanded in this remarkable retreat was Captain Hulke of the navy.

OMOPHAGIA, an ancient Greek feſtival, in honour of Bacchus, ſurnamed *Omophagos*, i. e. eater of raw fleſh. This feſtival was obſerved in the ſame manner with the other feſtivals of Bacchus, in which they counterfeited madneſs. What was peculiar to it, was, that the worſhippers uſed to eat the entrails of goats, raw and bloody, in imitation of the god, who was ſuppoſed to do the ſame thing.

OMPHACINE OIL, a viſcous brown juice extracted from green olives. With this oil the ancient *athletæ*, when going to wreſtle, anointed themſelves; and when that gymnaſtic exerciſe was over, they rolled themſelves in the ſand, which, mixing with the oil and ſweat on their bodies, conſtituted the *ſtrigmenta* ſo highly eſteemed in the cure of ſeveral diſeaſes. This precious medicine was carefully ſcraped off the body of the athleta with a kind of inſtrument ſomething like a comb, which was called *ſtrigilis*; and ſuch was the demand for the ſcrapings, that they were a very lucrative article of trade.

OMPHALE (fab. hiſt.), a queen of Lydia, daughter of Jardanus. She married Tmolus, who at his death left her miſtreſs of his kingdom. Omphale had been informed of the great exploits of Hercules, and wiſhed to ſee ſo illuſtrious a hero. Her wiſh was ſoon gratified. After the murder of Eurytus, Hercules fell ſick, and was ordered to be ſold as a ſlave, that he might recover his health and the right uſe of his ſenſes. Mercury was commiſſioned to ſell him, and Omphale bought him, and reſtored him to liberty. The hero became enamoured of his miſtreſs, and the queen favoured his paſſion, and had a ſon by him, whom ſome call Agelaus, and others Lamon. From this ſon were deſcended Gyges and Crœſus; but this opinion is different from the account which makes theſe Lydian monarchs ſpring from Alcæus, a ſon of Hercules, by one of the female ſervants of Omphale. Hercules is repreſented by the poets as ſo deſperately enamoured of the queen, that, to conciliate her eſteem, he ſpins by her ſide among her women, while ſhe covers herſelf with the lion's ſkin, and arms herſelf with the club of the hero, and often ſtrikes him with her ſandals, for the uncouth manner with which he holds the diſtaff, &c. Their fondneſs was mutual. As they once travelled together, they came to a grotto on Mount Tmolus, where the queen dreſſed herſelf in the habit of her lover, and obliged him to appear in a female garment. After they had ſupped, they both retired to reſt in different rooms, as a ſacrifice on the morrow to Bacchus required. In the night Faunus, or rather Pan, who was enamoured of Omphale, introduced himſelf into the cave. He went to the bed of the queen, but the lion's ſkin perſuaded him that it was the dreſs of Hercules; and therefore he repaired to the bed of Hercules, in hopes to find there the object of his affections. The female dreſs of Hercules deceived him, and he laid himſelf down by his ſide. The hero was awakened, and kicked the intruder into the middle of the cave. The noiſe awoke Omphale, and Faunus was diſcovered lying on the ground, greatly diſappointed and aſhamed.

OMPHALEA, in botany: A genus of the triandria order, belonging to the monœcia claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The male calyx is tetraphyllous; there is no corolla; the receptacle, into which the antheræ are ſunk, is ovate. The female calyx and corolla are as in the male; the ſtigma trifid; the capſule carnous and trilocular, with one ſeed.

OMPHALO-MESENTERIC, in anatomy. All fœtuſes are wrapped up in at leaſt two coats or membranes; moſt of them have a third, called *allantoides*, or *urinary*.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood veſſels, viz. a vein and an artery, called *omphalo-meſenterics*, becauſe paſſing along the ſtring to the navel, and terminating in the meſentery.

OMRAH, a man of the firſt rank in the Mogul empire; a nobleman. It is the plural of the Arabic *ameer*.

ON, (anc. geog.), a city of Egypt ſacred to the ſun, and by the Greeks, on that account, called *Heliopolis*. (See HELIOPOLIS.) It was remarkable for the wiſdom and learning of its prieſthood, and for the ſpacious buildings in which they cultivated the ſtudies of philoſophy and aſtronomy. The prieſts of On were eſteemed more noble than all the other prieſts of Egypt. They were always privy counſellors and miniſters of ſtate; and therefore, when Pharaoh reſolved to make Joſeph *prime* miniſter, he very wiſely gave him in marriage a daughter of the prieſt of *On*, thereby incorporating him into the moſt venerable caſt in Egypt. Biſhop Warburton thinks that the ſuperior nobility of the prieſts of *On* was chiefly owing to their high antiquity and great learning. That they were much given to the ſtudy of aſtronomy, we know from the teſtimony of Strabo; and indeed nothing is more probable than that they ſhould be attached to the ſtudy of that ſyſtem over which their god, the SUN, preſided, not only in his *moral* but alſo in his *natural* capacity. The learned prelate affirms, that "whether they received the doctrine from original tradition, or invented it at hazard (which laſt ſuppoſition he thinks more probable, though we are of a very different opinion), it is certain they taught that the Sun is in the centre of its ſyſtem, and that all the other bodies move round it in perpetual revolutions. This noble theory (he continues) came with the reſt of the Egyptian learning into Greece (being brought thither by Pythagoras, who received it from Oenuphis*, a prieſt of On); and after having given the moſt diſtinguiſhed luſtre to his ſchool, it ſunk into obſcurity, and ſuffered a total eclipſe throughout a long ſucceſſion of learned and unlearned ages; till theſe times reſtored its ancient ſplendour, and immoveably fixed it on the unerring principles of ſcience."

If it be true, as ſome philoſophers allege, that Moſes appears from the firſt chapter of Geneſis to have been acquainted with the true ſolar ſyſtem, this account of the origin of that ſyſtem is extremely improbable. As it is of no importance to the civil or religious conſtitution of a ſtate whether the ſyſtem of Ptolemy or that of Copernicus be admitted by the people, we cannot reaſonably ſuppoſe that the Jewiſh lawgiver was taught aſtronomy by a revelation from Heaven. But there can be no doubt of his knowing as much of that ſcience as the prieſts of *On*; for we know that he was inſtructed in all the wiſdom of the Egyptians; and therefore, if he held the ſun to be in the centre of the ſyſtem, it is morally certain that the ſame thing was held by that prieſthood.

ONANIA, or ONANISM, terms lately framed to denote the crime of ſelf-pollution, mentioned in Scrip-

Onania.

Onania ‖ Oneehoura and Oneehow.

ture to have been committed by Onan, and puniſhed in him with death.

This practice, however common, hath among all nations been reckoned a very great crime. In Scripture, beſides the inſtance of Onan above mentioned, we find ſelf-polluters termed *effeminate*, *unclean*, *filthy*, and *abominable*. Even the heathens, who had not the advantage of revelation, were of the ſame opinion, as appears from the following lines of Martial.

Hoc nihil eſſe putes! ſcelus eſt, mihi crede; ſed ingens
Quantum vix animo concipis ipſe tuo.

You think 'tis nothing! 'tis a crime, believe!
A crime ſo great you ſcarcely can conceive.

Dr Tiſſot has publiſhed a treatiſe on the pernicious effects of this ſhameful practice, which appears to be no leſs baneful to the mind than to the body. He begins with obſerving, that, by the continual waſte of the human body, aliments are required for our ſupport. Theſe aliments, however, require certain preparations in the body itſelf; and when by any means we become ſo altered that theſe preparations cannot be effected, the beſt aliments then prove inſufficient for the ſupport of the body. Of all the cauſes by which this morbid alteration is brought on, none is more common than too copious evacuations; and of all evacuations, that of the ſemen is the moſt pernicious when carried to exceſs. It is alſo to be obſerved, that though exceſs in natural venery is productive of very dangerous diſorders, yet an equal evacuation by ſelf-pollution, which is an unnatural way, is productive of others ſtill more to be dreaded. The conſequences enumerated by Dr Tiſſot are as follow:

1. All the intellectual faculties are weakened: the memory fails; the ideas are confuſed, and the patient ſometimes even falls into a ſlight degree of inſanity. They are continually under a kind of inward reſtleſsneſs, and feel a conſtant anguiſh. They are ſubject to giddineſs; all the ſenſes, eſpecially thoſe of ſeeing and hearing, grow weaker and weaker, and they are ſubject to frightful dreams.

2. The ſtrength entirely fails, and the growth in young perſons is conſiderably checked. Some are afflicted with almoſt continual watching, and others doſe almoſt perpetually. Almoſt all of them become hypochondriac or hyſteric, and are afflicted with all the evils which attend theſe diſorders. Some have been known to ſpit calcareous matters; and others are afflicted with coughs, ſlow fevers, and conſumptions.

3. The patients are affected with the moſt acute pains in different parts of the body, as the head, breaſt, ſtomach, and inteſtines; while ſome complain of an obtuſe ſenſation of pain all over the body on the ſlighteſt impreſſion.

4. There are not only to be ſeen pimples on the face, which are one of the moſt common ſymptoms; but even blotches, or ſuppurative puſtules, appear on the face, noſe, breaſt, and thighs; and ſometimes fleſhy excreſcences ariſe on the forehead.

5. The organs of generation are alſo affected; and the ſemen is evacuted on the ſlighteſt irritation, even that of going to ſtool. Numbers are afflicted with an habitual gonorrhœa, which entirely deſtroys the vigour of the conſtitution, and the matter of it reſembles a fetid ſanies. Others are affected with painful priapiſms, dyſuries, ſtranguries, and heat of urine, with painful tumours in the teſticles, penis, bladder, and ſpermatic cord; and impotence in a greater or leſs degree is the never-failing conſequence of this deteſtable vice.

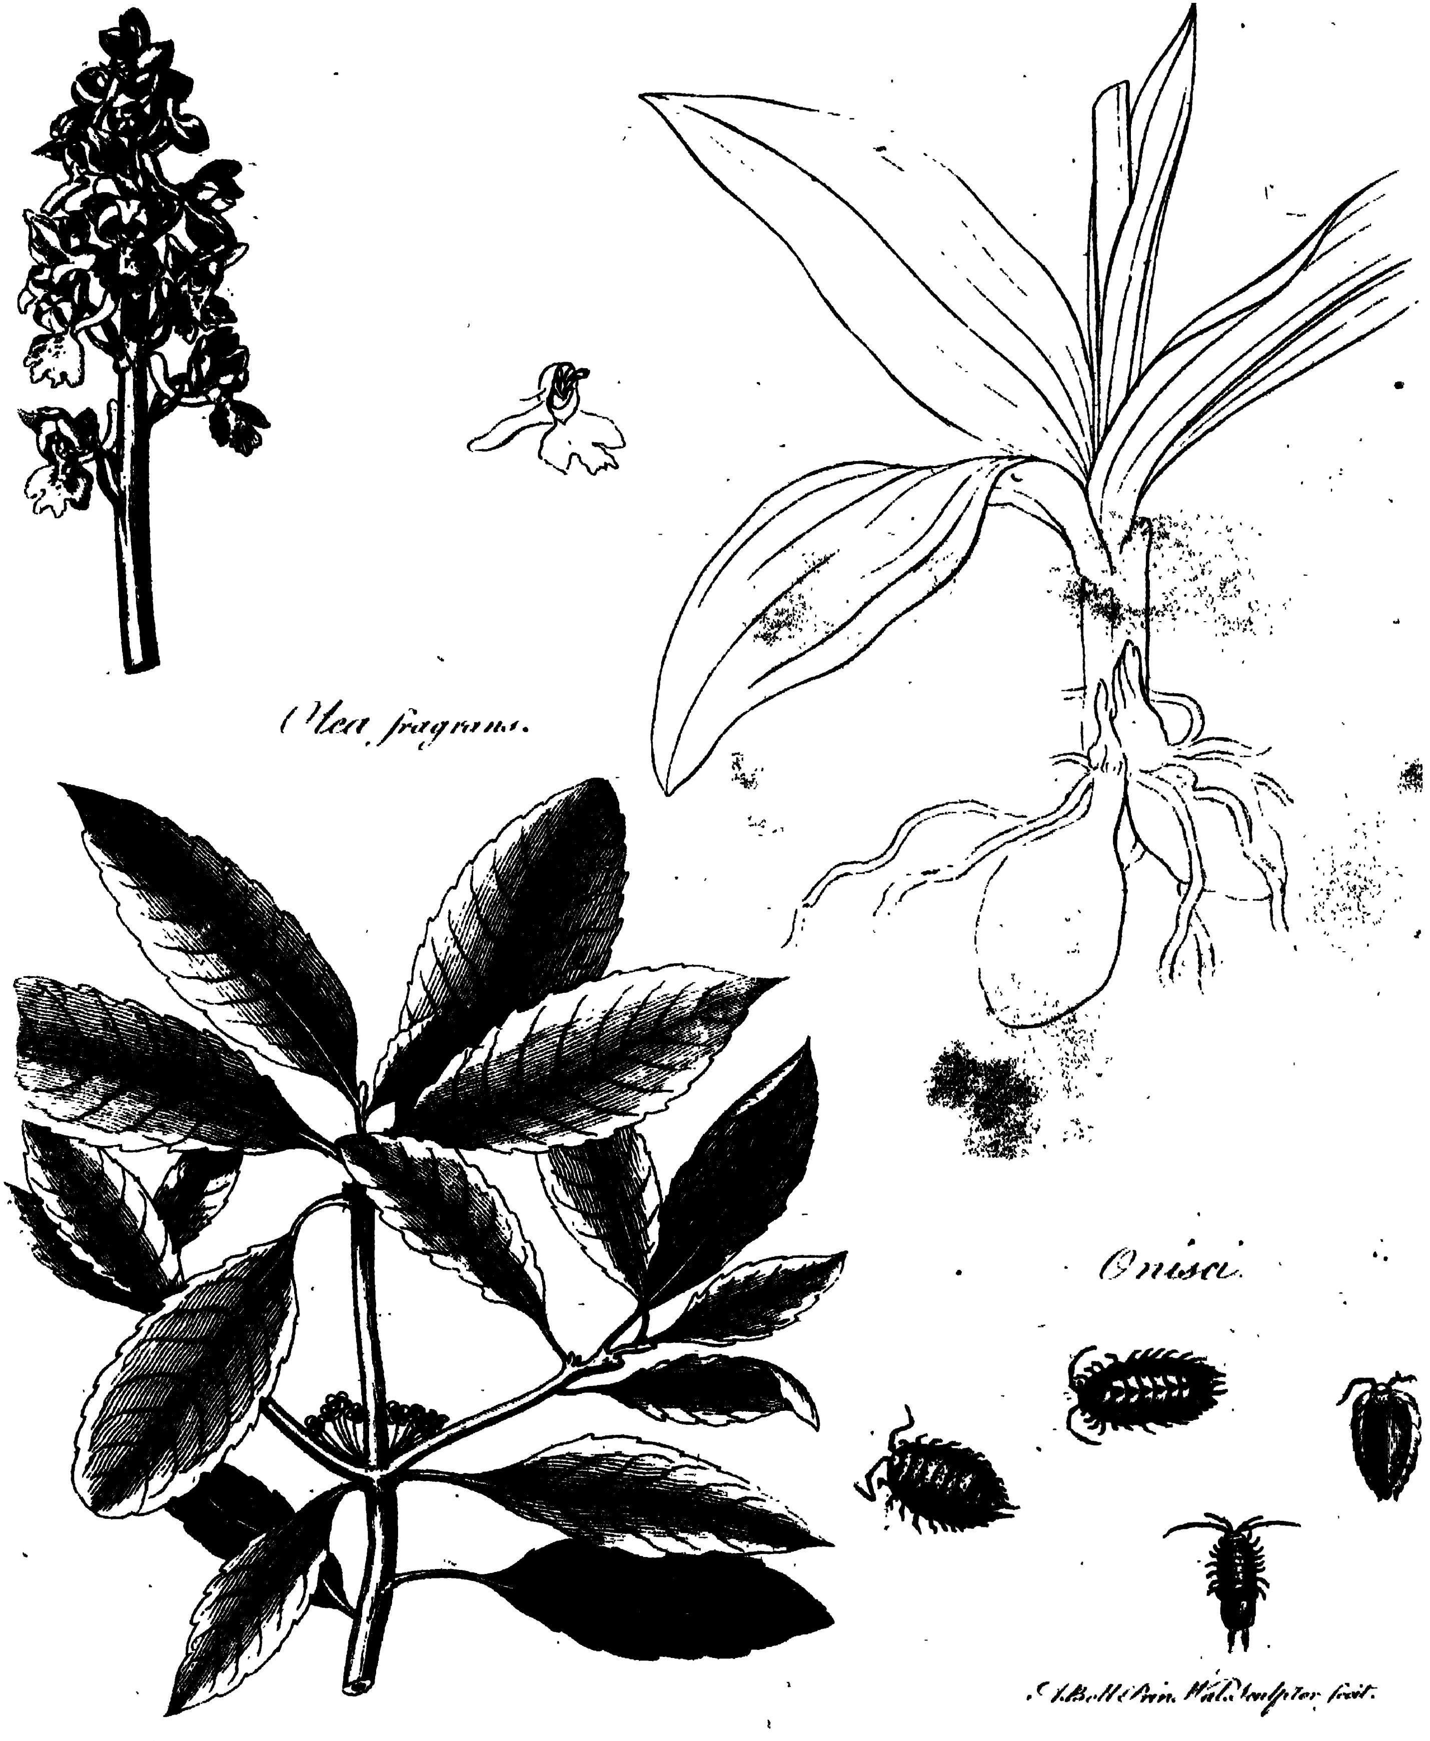
6. The functions of the inteſtines are ſometimes totally deſtroyed; and ſome patients complain of coſtiveneſs, others of diarrhœa, piles, and the running of a fetid matter from the fundament.

With regard to the cure, the firſt ſtep is to leave off thoſe practices which have occaſioned the diſeaſe; which our author aſſerts is no eaſy matter; as, according to him, the ſoul itſelf becomes polluted, and can dwell on no other idea; or if ſhe does, the irritability of the parts of generation themſelves quickly recal ideas of the ſame kind. This irritability is no doubt much more to be dreaded than any pollution the ſoul can have received; and by removing it, there will be no occaſion for exhortations to diſcontinue the practice. The principal means for diminiſhing this irritability are, in the firſt place, to avoid all ſtimulating, acrid, and ſpiced meats. A low diet, however, is improper, becauſe it would further reduce the body, already too much emaciated. The food ſhould therefore be nutritive, but plain, and ſhould conſiſt of fleſh rather roaſted than boiled, rich broths, &c. It is certain, however, that as theſe foods contribute to reſtore the ſtrength of the body, the ſtimulus on the organs of generation will be proportionably increaſed by the ſemen which is conſtantly ſecreted, and which will now be in larger quantity than even in healthy perſons, owing to the great evacuations of it which have preceded. Some part of the ſemen is gradually abſorbed by the lymphatics; in conſequence of which, the remainder becomes thick, acrid, and very ſtimulating. To remedy this, exerciſe is to be uſed, and that not only for pleaſure, but till it is attended with a very conſiderable degree of fatigue. The ſleep alſo muſt be no more than is barely ſufficient to repair the fatigue occaſioned by the exerciſe, or other employment; for an exceſs in ſleep is as bad as idleneſs or ſtimulating foods. Exceſs in wine or intoxicating liquors is alſo to be avoided; or rather ſuch liquors ought never to be taſted, unleſs as a medicine to reſtore the exhauſted ſpirits; and to all this ought to be joined the Peruvian bark, which hath this admirable property, that, with little or no ſtimulus, it reſtores the tone of the ſyſtem, and invigorates the body in a manner incredible to thoſe who have not obſerved its effects. If theſe directions are followed, the patient may almoſt certainly expect a recovery, provided any degree of vital ſtrength remains; and thoſe who deſire a life of celibacy on a moral account, will find them much more effectual than all the vows of chaſtity they can make.

ONCA and ONCE. See FELIS, IV. and VI.

ONEEHOURA and ONEEHOW, two ſmall iſlands of that cluſter which was diſcovered by Captain Cook, and by him called the *Sandwich Iſlands*. (See SANDWICH ISLANDS). *Oneehoura* is very ſmall, and its chief produce is yams. *Oneehow* is conſiderably larger, being about ten miles over. It is remarkable for the great quantity of excellent yams, which it produces, and for a ſweet root called *tee* or *tea*, which is generally

Plate CCCXLIX.



Orchis-mascula.
Olea fragrans.
Onisci.

A. Bell Prin. Wal. Sculptor fecit.

ly about the thickneſs of a man's wriſt, though ſometimes much larger. This root, which the natives commonly bake previous to their bringing it to market, is of a wet clammy nature, and with proper management makes excellent beer.

ONEGA, a river and lake of the Ruſſian empire, between Muſcovite Carelia, the territory of Cargapol, and Swediſh Carelia. It is 100 miles in length and 40 in breadth, having a communication with the lake Ladoga, and conſequently with Peterſburgh. The river has its ſource in Cargapol, and gives its name to a country full of woods.

ONEGLIA, a ſea port town of Italy, in the territory of Genoa, with the title of a principality; but it belongs to the king of Sardinia, as well as the province, which abounds in olive trees, fruit, and wine. It has often been taken and retaken in the wars of Italy; which is no wonder, as it is an open place. The French and Spaniards had poſſeſſion of it in 1744, but were driven out by the Piedmonteſe; however, they returned next winter, and again made themſelves maſters of it. E. Long. 7. 51. N. Lat. 43. 58.

ONEIROCRITICA, the art of interpreting dreams; or a method of foretelling future events by means of dreams. See DREAM, DIVINATION, &c.—The word is formed from the Greek ονειρος, "dream," and κριτικη, of κρισις, "judgment."—Some call it *oneirocratica*; and derive it from ονειρος and κρατεω, "I poſſeſs, I command."

It appears from ſeveral paſſages of Scripture, that there was, under the Jewiſh diſpenſation, ſuch a thing as foretelling future events by dreams; but then there was a particular gift or revelation required for that purpoſe.

Hence it has been inferred, that dreams are really ſignificative, and do forbode ſomething to come; and all that is wanting among us is the *oneirocritica*, or the art of knowing what: yet it is the opinion of many, that dreams are mere chimeras; bearing indeed ſome relation to what has paſſed, but none to what is to come. As to the caſe of Joſeph, it was poſſible for God, who knew all things, to diſcover to him what was in the womb of fate; and to introduce that, he might take the occaſion of a dream.

ONEIROCRITICS, a title given to interpreters of dreams, or thoſe who judge of events from the circumſtances of dreams.

There is no great regard to be had to thoſe Greek books called *oneirocritics*; nor do we know why the patriarch of Conſtantinople, and others, ſhould amuſe themſelves with writing on ſo pitiful a ſubject.

Rigault has given us a collection of the Greek and Latin works of this kind; one attributed to Aſtrampſichus; another to Nicephorus, patriarch of Conſtantinople; to which are added the treatiſes of Artemidorus and Achmet. But the books themſelves are little elſe than reveries; a kind of waking dreams, to explain and account for ſleeping ones.

The ſecret of oneirocriticiſm, according to them all, conſiſts in the relation ſuppoſed to be between the dream and the thing ſignified: but they are far from keeping to the relations of agreement and ſimilitude; and frequently have recourſe to others of diſſimilitude and contrariety. Concerning oneirocritics and oneirocritica, the unlearned reader will find much information in Warburton's Divine Legation of Moſes, and the books to which he refers.

ONESIÆ THERMÆ, were, according to Strabo, *excellent baths*, and *ſalutary waters*, at the foot of the Pyrenees in Aquitania. Near the river Aturus ſtands at this day the town Bagneres, famous for its waters, which appear to be the *Oneſiæ* of Strabo; ſituated in the county of Bigorre in Gaſcony, near the river Adour.

ONIÆ OPPIDUM and *Templum*, (Joſephus); ſo called from Onias, the high-prieſt of the Jews in Egypt; who built a temple in imitation of that at Jeruſalem, by permiſſion of the king of Egypt, on the ſpot where ſtood the temple of Diana Agreſtis in Leontopolis: it was encompaſſed with a brick wall, and had a large tower like that at Jeruſalem, (Joſephus): it was the metropolis of the Nomos Heliopolites, (Ptolemy); becauſe in Strabo's time Heliopolis was fallen to decay.

ONGLEE, in heraldry, an appellation given to the talons or claws of beaſts or birds, when borne of a different colour from that of the body of the animal.

ONION. See ALLIUM, ſp. 5.—Onions, leeks, and garlic, are all of the ſame genus; and in their recent ſtate are acrid, but harmleſs to the human body. When, by age or climate, this acrimony is too great, we do not uſe them as food. In Spain, the garlic being equally mild with the onion, is uſed as common food. By the ordinary culinary preparation their acrimony is diſſipated, and a remarkably mild ſubſtance remains, promiſing much nutriment, which thoſe who can digeſt them raw will certainly obtain. Though ſometimes ſhunned as food, yet they are on that account uſed in medicine, uniting the two qualities of pectorals, viz. on the account of their acrimony, being in their recent ſtate expectorant; in their boiled ſtate, on account of their mucilage, demulcent, provided the quantity taken be ſufficient. Some of late, in this country, have found in leeks a ſomniferous quality; but this is not yet confirmed by a ſufficient number of experiments.—Beſides the three above-mentioned, there are ſeveral others belonging to the ſame tribe, which we uſe as condiment; but only the leek and onion as diet. In its recent ſtate, the onion is the moſt acrid; in its boiled ſtate, the leek retains its acrimony moſt tenaciouſly. On account of this, and ſome difference of texture, the onion is more eaſily digeſted and more univerſally uſed than the leek; being more eaſily broke down, and more generally agreeable.

Plate CCCXLIX.

ONISCUS, in zoology, a genus of inſects belonging to the order of aptera. It has 14 legs, briſtly feelers, and an oval body. There are 15 ſpecies; of which the moſt remarkable are,

1. The *entomon*, or *ſea wood-louſe*, is white; eyes black; convex above, beneath flat, margin acute; antennæ 4: Four hind pair of legs largeſt, hairy. Body of 10 ſegments. Length 1½ line. Found on the coaſt. It accompanies the herring, and is an enemy well known to our fiſhermen; theſe inſects will frequently eat up a whole fiſh while it hangs in the net.

2. *Oniſcus aquaticus*, is of an aſhen colour, and tolerably ſmooth. Its body is compoſed of ſeven articulations, excluſive of the head and tail; which laſt part

is much larger than the other ſegments, round at the extremity, and from which iſſue two appendices, each divided into two threads. This inſect has that in common with ſome ſea oniſci, but differs from them by the ſea ones having ten ſegments. This has ſeven legs on each ſide; the laſt of which gradually increaſe in length, and are conſtantly larger than the foremoſt.—The antennæ have but three long articulations, the laſt of which is much longer than the reſt. This inſect is found in pools, ſmall rivulets, and eſpecially in ſprings.

3. *Aſellus, millepes*, or *wood-louſe*, is oval; the tail obtuſe, with two undivided briſtles: various as to colour: length, five lines. Their uſe in medicine is well known.

4. *Oniſcus armadillo* is broad, very gloſſy, and ſmooth: its colour is black, with a ſmall portion of white on the edge of the ſegment, which colour often varies; but ſtill the inſect is gloſſy and ſmooth. Its body is compoſed of ten ſegments, beſides the head and tail.—Of the ten ſegments, the firſt ſeven are broad, and the laſt three ſhort. The firſt of theſe three appears divided in the middle, which is broader than the reſt, into three more. Theſe laſt ſhort ſegments, with that of the tail, form the extremity of the animal's body, which is round, without any appendix, and conſtitutes the ſpecific character of this inſect. It has fourteen feet, ſeven on each ſide. This oniſcus, when touched, rolls itſelf up into a ball, bringing its head and tail together like the animal called *armadillo*, and neither antennæ nor feet are ſeen: it might be taken for a round, ſhining pearl. This oniſcus is found in woods.

ONKELOS, ſurnamed the *Proſelyte*, a famous rabbi of the firſt century, and the author of the Chaldee Targum on the Pentateuch. He flouriſhed in the time of Jeſus Chriſt, according to the Jewiſh writers; who all agree that he was, at leaſt in ſome part of his life, contemporary with Jonathan Ben Uzziel, author of the ſecond Targum upon the prophets. Dean Prideaux thinks he was the elder of the two, for ſeveral reaſons: the chief of which is the purity of the ſtyle in his Targum, therein coming neareſt to that part of Daniel and Ezra which is in the Chaldee, and is the trueſt ſtandard of that language, and conſequently is the moſt ancient; ſince that language, as well as others, was in a conſtant flux, and continued deviating in every age from the original: nor does there ſeem to be any reaſon why Jonathan Ben Uzziel, when he undertook his Targum, ſhould paſs over the law, and begin with the prophets, but that he found Onkelos had done this work before him, and with a ſucceſs which he could not exceed.

Azarias, the author of a book entitled *Meor Enaim*, or the *light of the eyes*, tells us, that Onkelos was a proſelyte in the time of Hillel and Samnai, and lived to ſee Jonathan Ben Uzziel one of the prime ſcholars of Hillel. Theſe three doctors flouriſhed 12 years before Chriſt, according to the chronology of Gauz; who adds, that Onkelos was contemporary with Gamaliel the elder, St Paul's maſter, who was the grandſon of Hillel, who lived 28 years after Chriſt, and did not die till 18 years before the deſtruction of Jeruſalem. He the ſame Gauz, by his calculation, places Onkelos 100 years after Chriſt; and to adjuſt his opinion with that of Azarias, extends the life of Onkelos to a great length. The Talmudiſts tell us that he aſſiſted at the funeral of Gamaliel, and was at a prodigious expence to make it moſt magnificent. Dean Prideaux obſerves, that the Targum of Onkelos is rather a verſion than a paraphraſe; ſince it renders the Hebrew text word for word, and for the moſt part accurately and exactly, and is by much the beſt of all this ſort: and therefore it has always been held in eſteem among the Jews much above all the other Targums: and being ſet to the ſame muſical notes with the Hebrew text, is thereby made capable of being read in the ſame tone with it in their public aſſemblies.—From the excellency and accuracy of Onkelos's Targum, the dean alſo concludes him to have been a native Jew, ſince without being bred up from his birth in the Jewiſh religion and learning, and long exerciſed in all the rites and doctrines thereof, and being alſo thoroughly ſkilled in both the Hebrew and Chaldee languages, as far as a native Jew could be, he can ſcarce be thought thoroughly adequate to that work which he performed; and that the repreſenting him as a proſelyte ſeems to have proceeded from the error of taking him to have been the ſame with Akilas, or Aquila, of Pontus, author of the Greek Targum or verſion of the prophets and Hagiographia, who was indeed a Jewiſh proſelyte.

ONKOTOMY, in ſurgery, the opening of a tumour or abſceſs. See SURGERY.

ONOCLEA, in botany: A genus of the natural order of filices, belonging to the cryptogamia claſs of plants. The ſpike is flat, and turned to each ſide, with quinquevalved fructifications.

ONOMANCIA, or rather ONOMANTIA, a branch of divination, which foretels the good or bad fortune of a man, from the letters in his name. See the article DIVINATION, and NAME.

From much the ſame principle the young Romans toaſted their miſtreſſes as often as there were letters in their names: Hence Martial ſays,

Nævia ſex cyathis, ſeptem Juſtina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to reſemble the ſound made by the thing ſignified; as the buzz of bees, the cackling of hens, &c. Reſemblances of this kind are often fancied when they are not real, though, no doubt, there are in every language ſome words of which the ſound is very like to that which thoſe words are employed to expreſs. Yet, to the mortification of grammarians and rhetoricians, conjunctions, which have been juſtly pronounced no parts of ſpeech, are the only ſounds uttered by men that are wholly natural, and theſe are fewer than is commonly ſuppoſed. See GRAMMAR and LANGUAGE.

ONONIS, in botany: A genus of the decandria order, belonging to the diadelphia claſs of plants. The calyx is quinquepartite, with the ſegments linear; the vexillum ſtriated; the legumen turgid and ſeſſile; the filaments coalited without a fiſſure.

ONOPORDUM, in botany: A genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants; and in the natural method ranking under the 49th order, *Compoſitæ*. The receptacle is honeycombed; the ſcales of the calyx mucronated or pointed.

ONOSANDER, a Greek author and Platonic philoſopher, who wrote Commentaries on Plato's Politics, which are loſt: but his name is particularly famous for a treatiſe entitled Λογος Στρατηγικος, "Of the duty and virtues of the general of an army;" which has been tranſlated into Latin, Italian, Spaniſh, and French. The time when he lived is not preciſely known: but is imagined to be in the reign of the emperor Claudius.

ONOSMA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 41ſt order, *Aſperifoliæ*. The corolla is campanulated, with the throat pervious: there are four ſeeds.

ONTARIO, a lake of North America, in the country of the Iroquois, 180 miles in length and 60 in breadth. There are many rivers that run into it; and from it the great river St Lawrence proceeds. It communicates with the lake Erie by a river 33 miles in length, in which is the remarkable cataract of NIAGARA.

ONTOLOGY. See METAPHYSICS, N° 3.

ONUPHRIUS PANVINUS, a learned Italian, of the order of hermits of St Auguſtine, was born of a noble family at Verona, in 1529; and, being trained to literature, became ſo indefatigable in his ſtudies, that he ſpent whole days and nights in reading the ancients: which made Manutius ſtyle him *Helluo Antiquitatis*. His firſt performance was a Chronicle of Popes and Cardinals, which was printed without his knowledge at Venice in 1557; and ſome time after, more correctly by himſelf. He afterwards continued Platina's Lives of the Popes, from Sixtus IV. to Pius V. and ſubjoined annotations to the lives Platina had written. He alſo wrote four pieces upon Roman Antiquities, which are printed in Grævius's Collection. He died in his 39th year, in 1568.

ONYCOMANCY, or, as ſome write it, ONYMANCY; a kind of divination by means of the nails of the fingers.——The word is formed from the Greek ονυξ, "nail," and μαντεια, "divination."

The ancient practice was to rub the nails of a youth with oil and ſoot, or wax; and to hold up the nails thus ſmeared againſt the ſun.—Upon them were ſuppoſed to appear figures or characters, which ſhowed the thing required.

ONYX, in natural hiſtory, one of the ſemipellucid gems, with variouſly coloured zones, but none red: being compoſed of cryſtal, debaſed by a ſmall admixture of earth; and made up either of a number of flat plates, or of a ſeries of coats ſurrounding a central nucleus, and ſeparated from each other by veins of a different colour, reſembling zones or belts.

We have four ſpecies of this gem. 1. A bluiſh white one, with broad white zones. 2. A very pure onyx, with ſnow-white veins. 3. The jaſponyx, or horny onyx, with green zones. 4. The brown onyx, with bluiſh white zones.

The ancients attributed wonderful properties to the onyx, and imagined that if worn on the finger it acted as a cardiac; they have alſo recommended it as an aſtringent: but at preſent no regard is paid to it.

The word in the Greek language ſignifies *nail*; the poets making this ſtone to have been formed by the Parcæ from a piece of Venus's nails, cut off by Cupid with one of his arrows.

OONALASHKA, one of the iſlands of the Northern Archipelago, viſited by Captain Cook in his laſt voyage. The native inhabitants of this iſland are, to all appearances, a very peaceable people, having been much poliſhed by the Ruſſians, who now keep them in a ſtate of ſubjection. As the iſland furniſhes them with ſubſiſtence, ſo it does, in ſome meaſure, with clothing, which is chiefly compoſed of ſkins. The upper garment, which is made like a waggoner's frock, reaches down to the knees. Beſides this, they wear a waiſtcoat or two, a pair of breeches, a fur cap, and a pair of boots, the legs of which are formed of ſome kind of ſtrong gut; but the ſoles and upper-leathers are of Ruſſia leather. Fiſh and other ſea animals, birds, roots, berries, and even ſea weed, compoſe their food. They dry quantities of fiſh during the ſummer, which they lay up in ſmall huts for their uſe in winter. They did not appear to be very deſirous of iron, nor to want any other inſtrument, except ſewing needles, their own being formed of bone. With theſe they ſew their canoes, and make their clothes, and alſo work their curious embroidery. They uſe, inſtead of thread, the fibres of plants, which they ſplit to the thickneſs required. All ſewing is performed by the females, who are ſhoemakers, tailors, and boat-builders. They manufacture mats and baſkets of graſs, which are both ſtrong and beautiful. There is indeed a neatneſs and perfection in moſt of their works, that ſhows they are deficient neither in ingenuity nor perſeverance.

Though the climate is ſometimes ſevere, Captain Cook did not obſerve a fire-place in any of their habitations. They are lighted as well as heated by lamps; which, though ſimple, effectually anſwer the purpoſe for which they are intended. They conſiſt of a flat ſtone, hollowed on one ſide like a plate; in the hollow part they put the oil, mixed with ſome dry graſs, which ſerves for a wick. Both ſexes often warm themſelves over one of theſe lamps, by placing it between their legs, under their garments, and ſitting thus over it for ſeveral minutes. E. Long. 139. 29. N. Lat. 53. 5.

OONELLA, OONEMAH, two iſlands of the ſame Archipelago with Oonalaſhka; the former of which lies to the north-eaſt of that iſland, being ſeparated from it by a navigable ſtrait; the other is more to the weſtward, being in E. Long. 192. 30. and N. Lat. 54. 30. The circumference of Oonella is about ſeven leagues, and the produce of both much the ſame with that of Oonalaſhka.

OORT (Adam Van), born at Antwerp in 1557, was the ſon of Lambert Van Oort, a painter of conſiderable reputation for perſpective and architecture. Adam was inſtructed in the art by his father, and afforded ſufficient proofs of his having an enlarged genius; ſo that he ſoon roſe into eſteem, not only as a painter of hiſtory, but as an able artiſt in landſcape and portrait. But the greateſt honour of Van Oort proceeded from his having been the firſt inſtructor of Rubens, whoſe works have eternized his maſter's memory, along with his own.

Ooſt. Naturally he was of a rough and diſagreeable temper, which occaſioned him to loſe the love of his diſciples and his friends; and among the number, he totally forfeited the eſteem of Rubens, his beſt pupil. Jordaens was the only perſon who accommodated himſelf to the ſavage humour of his maſter; but it appears probable, that he only condeſcended to endure his moroſe behaviour, out of affection to the daughter of Van Oort, to whom Jordaens was afterwards married.

In his ſtyle of painting, however, he neglected nature, and was entirely a manneriſt; nor did he ſeem to have any regard to painting as a fine art, but merely as an art that might be the means of making him rich. In his beſt time, his compoſition was agreeable and his deſign correct; but in his latter time, his works had nothing to recommend them, except the freedom of handling, and the goodneſs of their colouring; yet, with all his defects, he was accounted a good painter. Rubens uſed to ſay, that Van Oort would have ſurpaſſed all his contemporaries, if he had ſeen Rome, and formed his taſte by ſtudying after the beſt models. He painted a great number of deſigns for the altars of churches in Flanders, which have much merit in ſeveral parts; and they are ſtill beheld with pleaſure by good judges.

OOST, a kiln for drying hops after they are picked from the ſtalks.

Oost (Jaques Van), a painter of hiſtory, landſcape, and architecture, was born at Bruges about the year 1600, and learned the art in his native city, though it is not aſcertained by what maſter he was inſtructed; but he travelled to Italy to ſtudy after the works of the great maſters, and copied every thing that pleaſed his own taſte, or that he thought might contribute to his improvement. However, among all the famous artiſts, he attached himſelf particularly to the ſtyle of Annibal Caracci, and imitated him in ſuch a manner, as to ſurpriſe the moſt able connoiſſeurs at Rome.

He poſſeſſed many of the accompliſhments of a great painter. His touch and his colouring were good; he introduced but few figures in his deſigns, to avoid encumbering his ſubject; and he diſpoſed them with a great deal of ſkill and elegance; giving them ſuch draperies as were ſimple and natural. He deſigned in a good taſte; and though his ſtyle of compoſition reſembled that of Annibal, yet it was leſs charged than the deſigns of that maſter uſually are. In his carnations, his colouring was freſh and like nature; but he is not ſo commendable in the colour of his draperies, which is ſometimes ſo broken as to give the ſtuffs an appearance of hardneſs. He underſtood perſpective and architecture extremely well; and as he was not fond of painting landſcape (though occaſionally he painted it well), in the ſtead of it he ornamented his back grounds moſt frequently with buildings, columns, arches, and different pieces of architecture, which gave his compoſition a grand effect.

The moſt admired picture of Van Ooſt is in the church at Bruges which belonged to the Jeſuits: the ſubject of it is, a Deſcent from the Croſs; in which the deſign, the diſpoſition, the expreſſion, colour, and chiaro-ſcuro, are worthy of the higheſt praiſes. He had a ſon of the ſame name, who acquired conſiderable fame in his profeſſion.

Opacity, Opah. OPACITY, in philoſophy, a quality of bodies which renders them impervious to the rays of light.

Plate CCCLI. OPAH, commonly called the *king fiſh*. See Zeus. The body is deep; the ſcales exceedingly minute: it has ſetaceous teeth on the tongue only, one long dorſal fin, and a tail ſomewhat lunated. The genus of which this is a ſpecies is not numerous: This, however, is conſiderably the largeſt, and with reſpect to its colours the moſt ſplendid. It is conſidered by many as the moſt beautiful fiſh that is found on the coaſt of Europe. Mr Pennant in his Britiſh Zoology gives the following account of this fiſh, which is exceedingly rare on the Britiſh coaſt: "We have only four inſtances (ſays he) of this fiſh being taken in our ſeas, each of them in the north, viz. twice off Scotland, once off Northumberland, and once in Filey Bay, Yorkſhire. This laſt was caught about two years ago, and exhibited as a ſhow at Scarborough.

"It is of that genus which Linnæus diſtinguiſhes by the name of *Chætodon* from its briſtly teeth, and is ſaid to be very common on the coaſt of Guinea. See Chætodon. (a)

"It is well deſcribed by an anonymous writer in the London Magazine for October 1767, which we ſhall borrow, as the account is confirmed to us by Mr T who had an opportunity of examining one of the ſpecies.

"Newcaſtle, September 12. On Saturday was thrown upon the ſands at Blyth, a very rare and beautiful fiſh, weighing between 70 and 80 pounds, ſhaped like the ſea bream. The length was three feet and a half; the breadth from back to belly almoſt two feet; but the thickneſs from ſide to ſide not above ſix inches.

"The mouth ſmall for the ſize of the fiſh, forming a ſquare opening, and without any teeth in the jaws. The tongue thick, reſembling that of a man but rough and thick ſet with beards or prickles, pointing backward[illegible] that any thing might eaſily paſs down, but coul[illegible]ſily return back; therefore theſe might ſerve ſt[illegible] teeth to retain its prey. The eyes remarkably large, covered with a membrane, and ſhining with a glare of gold. The cover of the gills like the ſalmon.

"The body diminiſhes very ſmall to the tail, which is forked, and expands 12 inches: the gill fins are broad, about eight inches long, and play horizontally: a little behind their inſertion the back fin takes its original, where it is about ſeven inches high, but ſlopes away very ſuddenly, running down very near the tail, and, at its termination becomes a little broader: the belly fins are very ſtrong, and placed near the middle of the body: a narrow fin alſo runs from the anus to the tail.

(a) Later writers ſeem with more propriety to have ranked it under the genus *Zeus*, to which we have already referred.

"All the fins, and alſo the tail, are of a fine ſcarlet; but the colours and beauty of the reſt of the body, which is ſmooth and covered with almoſt imperceptible ſcales, beggars all deſcription; the upper part being a kind of bright green, variegated with whitiſh ſpots, and enriched with a ſhining golden hue, much reſembling the ſplendour of the peacock's feathers; this by degrees vaniſhes in a bright ſilver: and near the belly the gold begins again to predominate in a lighter ground than on the back."

OPAL, in natural hiſtory, a ſpecies of the chroaſtaces genus of gems.—This ſpecies of precious ſtone is generally eſteemed the moſt beautiful of all the flinty tribe, which appears to be owing to its changeable appearance when viewed by reflection.—The form of the opal is that of a pebble, like the agate, with which authors in general have claſſed it, from a ſuppoſed reſemblance of which there appears no ſort of proof. On the contrary, Bergman's analyſis points it out to be of a very different nature from the genus of flints, of which the agate is a ſpecies; magneſia conſtituting a large part of its compoſition, and not entering at all into that of the agate, if we are to judge from the analyſis of the parent ſpecies or flint, there being none yet publiſhed of agate. The ſpecific gravity of the opal is likewiſe extremely different from that of the agate. Wallerius tells us that its ſpecific gravity is upwards of 1900. It loſes its colour and tranſparency in the fire, and in other reſpects is affected by it in the very ſame manner as quartz or flint would be. It may be melted with borax, but not without great difficulty. The ſpecies are,

1. The opal of Nonnius. This appears olive-coloured by reflection, and then opaque; but when held between the eye and the light, it is found to be tranſparent, and appears of a beautiful ruby colour. Boccede Boot, author of the *Complete Jeweller*, conſiders it as the moſt precious ſort of opal, and indeed the moſt wonderful of this kind of nature's works: he gives a lofty encomium upon it, chiefly from Pliny, who called this opal *paderos*. This ſpecies of opal is the *ſangenon* of India, and *nonnius* of the ancients and modern Europeans, from the Roman ſenator Nonnius poſſeſſor of the famous opal of Rome, worth 20,000 ſeſterces, who preferred baniſhment to parting with it to Antony. An opal anſwering exactly to Pliny's deſcription of the nonnius was diſcovered about 30 or 35 years ago in the ruins of Alexandria, and purchaſed for a trifle by the French conſul Lironcourt, from his dragoman Roboly. The duke de Nivernois, when ambaſſador in London in 1763, was in poſſeſſion of the very ſtone. The next in eſteem and value is the Iris opal, of a glaſſy white colour, but when looked through it appears of a flame colour, as the nonnius does of a ruby.

Wallerius indeed is of opinion that the opal found in Alexandria was not that of Nonnius mentioned by Pliny; and adds, that it was by many ſuppoſed to be only a counterfeit piece of glaſs or paſte. There is another of the ſame ſpecies in Sweden, which by reflection appears of a browniſh colour, but by refraction is red with violet veins.

2. The white opal, having its ground of a white glaſs-like complexion, from whence green, yellow, bluiſh, and purple rays are thrown out; but when held againſt the light it appears of a reddiſh or rather flame colour. Wallerius, in his Mineralogy, ſays, that this white opal anſwers the deſcription of it given by Pliny much better than the olive-coloured one above deſcribed. There are two varieties of it: 1. The oriental opal, ſhowing many colours.—Engenſtroom informs us, that he had obtained a ſmall piece of pſeudo-agate from the Eaſt Indies, of a yellowiſh brown and pale blue, or rather milk colour, with a ſhining brightneſs exactly like that of the milky opals already mentioned; alſo ſome other ſpecimens near Turin in Piedmont, where they are called *baſtard agates*, a name which, in his opinion, is extremely proper for them, as they agree with the agates in almoſt every reſpect except hardneſs: this, however, has been controverted.—Sometimes the opal is ſurrounded with a white cruſt, like common flints in the ſtrata of chalk: which cruſt has likewiſe the ſame properties as the flint when this laſt mentioned ſubſtance has been previouſly freed from the adherent chalk; viz. 1. It does not diſſolve in nitrous acid. 2. It is not fuſible *per ſe*. 3. It melts pretty eaſily with borax, but without any efferveſcence, contrary to what is obſerved in calcareous ſubſtances; ſo that borax will diſſolve about three quarters of its own bulk of this ſubſtance, though with difficulty, eſpecially towards the end of the operation; but the glaſs becomes quite clear and colourleſs, inſtead of becoming white and opaque, as is the caſe with calcareous ſubſtances. This oriental ſtone is found in the iſland of Ceylon, where it is called the *elementary ſtone*. The Indians put as high a value on it as on the diamond. There is another kind of oriental opal much valued, generally called the *flaming opal*, becauſe it changes its colours, as if ſparks of fire eſcaped from it in parallel lines.

3. The bluiſh and ſemitranſparent opal is leſs valued by thoſe who are converſant in gems than the others, on account of its being ſuppoſed more eaſily imitable by art. M. Magellan, however, informs us, that not only this, but ſeveral other kinds of opals are eaſily imitable by art; ſeveral compoſitions of glaſs being met with which ſhow very different colours by reflection and by refraction. A curious ancient one of this kind is to be ſeen in the royal abbey of St Denis near Paris, which is green on the outſide, but ſhows a fine ruby colour when held between the eye and the light. Our author has alſo ſeen ſome glaſs paſtes made in London by Edward Delaval, Eſq; and others by Mr More ſecretary to the Society of Arts, which appeared of a yellow brown or other colour by reflection; but when held againſt the light tranſmitted a fine blue, purple, or red colour, like the ſapphires, rubies, garnets, and other precious ſtones. Wallerius gives directions for making theſe paſtes; and M. Magellan informs us, that he by chance diſcovered that the red glaſs of Kunckel, when over-melted or burnt in a common fire, produces a ſimilar effect, tranſmitting one colour by refraction and another by reflection. The fine imitations of the true white opals, which Pliny ſays were made by the Indians, have, in our author's opinion, hitherto baffled the art of the moderns.

The ſangenon or nonnius opal is found in the Eaſt Indies; the Iris, in Ceylon; the milky opal, at Eilbenſtock and Fryberg; the bluſh or moſt common and leaſt eſteemed, in Hungary, Sileſia, Saxony, &c.; the olive and bottle-coloured cat's eye, in Ceylon; the inferior in different countries of Europe. Mr Born mentions what he calls an *avanturine cat's eye*, of a fleſh colour and tranſparent, poſſeſſing the curious ſtructure of the avanturine, viz. compoſed of little plates like ſcales, with a metallic ſplendour, which reflects the rays of light like the opal. This ſtone we ſuſpect to be that which has led authors to claſs the avanturine with the opal, although it is in fact a fine opaque quartz. Ruſſia produces the opal at the rivulet Katſcha, near the city of Kraſnajark, in the Altai mountains in Siberia. The cat's eye is found in Mount Caucaſus, and is often confounded with the opal, though improperly. See Asteria. The oculus mundi (ſee Hydrophanes) has a very intimate connexion with opal, being generally found in beds over it, and being regarded by ſome naturaliſts as the ſame ſtone in a ſtate of decompoſition by the action of the air. Ruſſia poſſeſſes this ſtone in the Altai mountains, where the opals are found.

No method of eſtimating the opal is given by authors that we know of. But thoſe of uncommon beauty and ſize are ſold for very large ſums.

The late Leopald II. emperor of Germany, was in poſſeſſion of an oriental ſtone, ſometimes deſcribed as a cat's eye and ſometimes as an opal, of one inch diameter, and which was valued at a great price. Prince Potemkin, the Ruſſian general, purchaſed for 1000 ducats a ſtone of the ſame kind, ſaid to have been taken by the famous Nadir Shah from the head of a Gentoo idol, of which it made one of the eyes. By what circuitous road it found its way to Potemkin, we have not been informed; but with many other gems it diſappeared from the tent of the Perſian conqueror when he was aſſaſſinated.

Opals are commonly found in detached pieces, in an envelope of a different kind of ſtone, from the ſize of a pin head to that of a walnut. Beautiful opals of this laſt ſize are extremely rare; ſo that it is difficult to find an opal ſufficiently perfect and large to be completely poſſeſſed of all its beauties: this renders it ſo precious, and makes it almoſt impoſſible to determine its value. They have agreed, however, to value a beautiful oriental opal at double the price of a ſapphire of the ſame ſize.

It is very remarkable, that all the beautiful colours of the opal may entirely change or diſappear when the ſtone is divided into pieces. This phenomenon, which has been demonſtrated more than once by experience, leads us to think that all the ſparkling play of the opal is owing to the refraction of the rays of the ſun from the ſurface of the ſtone, which is naturally formed to produce this refraction.

OPALIA, in antiquity, feaſts celebrated at Rome in honour of the goddeſs Ops. Varro ſays they were held on the 19th of December, which was one of the days of the Saturnalia: theſe two feaſts were celebrated in the ſame month, becauſe Saturn and Ops were huſband and wife: the vows offered to the goddeſs were made ſitting on the ground.

OPERA, a dramatic compoſition ſet to muſic, and ſung on the ſtage, accompanied with muſical inſtruments, and enriched with magnificent dreſſes, machines, and other decorations.—This ſpecies of drama is of modern invention. In its preſent ſtate it was not known even in Italy before the beginning of the laſt century; and at its introduction into England, a century afterwards, it divided the wits, literati, and muſicians of the age. By thoſe who were eſteemed the beſt judges of the art, the Engliſh language was conſidered as too rough and inharmonious for the muſic of the opera; and, on the other hand, critics, whoſe taſte was built on the baſis of common ſenſe, looked upon a drama in a foreign and unknown tongue as the greateſt of all abſurdities. Many of them, however, pleaded for operas in the Engliſh language; and it is well known that Addiſon, who was one of the oppoſers of the Italian opera on the London ſtage, wrote in his native tongue the opera of Roſamond. This is confeſſedly a beautiful poem; but, in the opinion of Dr Burney, it adds nothing to Addiſon's fame, as it ſhows his total ignorance of the firſt principles of muſic, and of courſe his unfitneſs for the taſk he had undertaken.

In queſtions reſpecting the fine arts there is no appeal from the general taſte; and therefore, as the French opera, which is in the language of the country where it is acted, has always been admired by perſons of liberal education, it doubtleſs has merit conſidered as a drama; but how the dramas of this kind which are compoſed in Italian ſhould find admirers in England, among perſons who underſtood not a word of the language, is to us a matter of aſtoniſhment. The muſic of them may deſerve and command the admiration of every one who has an ear; and th action of the fingers may be perfectly ſuitable to the ſubject repreſented; but of this ſuitableneſs the majority of the audience can be no judges.

Even when the language is thoroughly underſtood, we ſhould imagine, that, to make an opera agreeable to good ſenſe, much would depend upon the choice of the ſubject; for it is ſurely abſurd to have perſons of all ranks, and on every occaſion, perpetually accompanied with the regular reſponſes of ſymphony. To hear Cæſar, Scipio, or Macbeth, when forming plans to enſure victory, or hatching plots of treaſon and murder, talk[illegible] recitative and keeping time with fiddles, wo[illegible]y diſguſt every perſon whoſe ſenſe had not all evaporated in ſound; but when the ſubject repreſented naturally admits of muſic in real life, we can ſuppoſe an opera to afford to perſons of taſte one of the moſt exquiſite and refined entertainments of which human nature is capable. For a further account of the opera, ſee Music, Nº 39, 42, 44, and Poetry, Nº [illegible], &c.

OPERATION, in general, the act of exerting or exerciſing ſome power or faculty, upon which an effect follows.

Operation, in ſurgery and medicine, denotes a methodical action of the hand on the human body, in order to re-eſtabliſh health.

Plate CCCLI.

OPHIDIUM, a genus of fiſhes belonging to the order of apodes. The principal characters of this genus are the following. The head is ſomewhat naked;

the teeth are in the jaws, palate, and fauces; the body long; the fins of the back, tail, and anus, confounded in one; no fin on the under part of the body; and the eyes covered by the common ſkin. Of this genus there are ſeveral ſpecies, of which the moſt curious is the *ophidium barbatum* of Linnæus, thus deſcribed by Dr Brouſſonet in the 71ſt volume of the Philoſophical Tranſactions.

"The ſcales of the ophidium (ſays he) are irregularly placed and diſperſed over the whole body. Their form is ſometimes round, ſometimes nearly oval. They are larger near the head, and in the lower part of the body; but are hardly to be diſtinguiſhed near the tail. They adhere to the body by means of a particular tranſparent ſkin, which is in general very thin, but ſomewhat thicker near the neck, and extended looſely over the whole head: this *ſkin* is very eaſily deſtroyed, after which the ſcales falling, the body appears ſpotted (fig. 1.) When you look at them with the naked eye (fig. 2.) they appear as covered with very ſmall grains; but viewed through a microſcope (fig. 3.) the middle of them appears more elevated than the margin; and from the centre to the margin, cloſe by each other, there are many lines or rays formed by ſmall ſcales placed upon one another, like tiles upon a roof, the ſuperior being always the nearer to the centre. This ſort of ſcales, which may be called *umbonatæ*, are faſtened to the body by very ſmall veſſels which are inſerted in their middle; they are to be ſeen on the body only, not on the head nor the fins."

The anatomy of this fiſh comprehends ſome very remarkable circumſtances, which, our author thinks, were never obſerved in any other ſpecies. When the ſkin is drawn off, there appears a thin membrane of a ſilver colour, which covers the muſcles. The muſcles being removed, we find the peritoneum, which lines the abdominal cavity, and is adherent to the ſwimming bladder by ſome elongations. It is of a ſilver hue, with ſome very ſmall black points. The ventricle is not to be diſtinguiſhed from the inteſtines by any other mark but by its ſize; its form is oblong; it is extended almoſt to the anus, from whence the inteſtinal duct has a retrograde courſe, and then deſcends again, having a little dilatation near the anus. On the vertebræ next the anus on the outſide of the peritoneum is a kind of cavity of an [illegible] form, containing a reddiſh viſcus, which he ta[illegible]e the kidney.

The firſt vertebra from the head has nothing very remarkable in its ſtructure. The ſecond has on each ſide an elongated and ſharp apophyſis, to the apex of which is annexed a ſmall ligament. The third is very flat, and has on each ſide a kind of triangular and ſharp apophyſis, to which adheres a ligament, as to the ſecond. The fourth is remarkable in having a ſharp apophyſis on each ſide, articulated with the body of the vertebra; and under each of them is another articulated apophyſis, flattiſh, thick, roundiſh at its extremities, and forked at its baſis (fig. 5.) The fifth, which is ſtrongly adherent to the former, has in its middle a bifid proceſs. The ſixth has in its middle a flattiſh elevation, ſharp on each ſide. Between the extremity of the larger apophyſis of the fourth vertebra is a bone, or rather a hard cartilage, which bears the figure of a kidney (fig. 6.) its convexity being turned towards the body of the vertebra: its poſition is parallel to the bodies of the vertebræ; its motion is half circular; one of its parts, *viz.* the loweſt, being in the cavity of the ſwimming bladder, to which it adheres by a thin membrane, ſo that no air can eſcape at that part. It is covered by membranes, which adhere ſtrongly to its middle; in this part are faſtened the two ligaments of the apophyſis of the ſecond and third vertebræ, of which we ſpoke before, and which are of a great tenuity. In the ſame point are faſtened alſo two ligaments, each of which belongs to an oblong muſcle parallel to each other, and fixed to the bones of the loweſt and poſterior part of the head (fig. 4.)

All this apparatus is certainly ſubſervient to the purpoſe of ſwimming; but it is very remarkable, that if theſe parts are neceſſary to ſome animal function, they ſhould not be found in all the individuals; "for I have ſeen (ſays our author) two, of which the vertebræ were not different from the vertebræ of the other ſpecies: which difference depends, perhaps, on the difference of ſex. I am inclined to believe ſo; but the generation in this fiſh ſeems to be no leſs myſterious than that of the eel: I could never diſtinguiſh a male from a female in this ſpecies."

This fiſh commonly grows to the ſize of eight or nine inches. It is to be found in all the Mediterranean ſea, and in great plenty in the Adriatic: its fleſh is not of a good taſte, rather coarſe, as is that of all the ſpecies of fiſhes which, having no ventral fins, are obliged to make great efforts in ſwimming, and have conſequently the muſcles harder.

OPHIOGLOSSUM, ADDER'S TONGUE: A genus of the natural order of filices, belonging to the cryptogamia claſs of plants. The ſpike is articulated, flat, and turned to the two ſides; with the articuli or joints opening acroſs. There are ſeven ſpecies; of which the only remarkable one is the vulgatum, or common adder's tongue, which is a native of ſeveral places of Britain, growing in meadows and moiſt paſtures. The country people make an ointment of the freſh leaves, and uſe it as a vulnerary to green wounds; which is a very ancient application, recommended by Matthiolus, Tragus, and others.

OPHIOMANCY, in antiquity, the art of making predictions from ſerpents. Thus Calchas, on ſeeing a ſerpent devour eight ſparrows with their dam, foretold the duration of the ſiege of Troy: and the ſeven coils of a ſerpent that was ſeen on Anchiſes's tomb, were interpreted to mean the ſeven years that Æneas wandered from place to place before he arrived at Latium.

OPHIORHIZA, in botany: A genus of the monogynia order, belonging to the pentandria claſs of plants; and in the natural method ranking under the 47th order, *Stellatæ.* The corolla is funnel-ſhaped: the capſule twin, bilocular, and polyſpermous. There are two ſpecies; the moſt remarkable of which is the Aſiaticum, or true lignum colubrinum. The root of this is known in the Eaſt Indies to be a ſpecific againſt the poiſon of the moſt dreadful animal called the *hooded ſerpent.* There is a treatiſe in *Amæn. Acad.* Tom. IV. upon this ſubject, wherein the author Joh. And. Darelius undertakes, from the deſcription of ſuch authors as had ſeen it upon the ſpot, to aſcertain the plant from which the genuine root is taken. It appears in this account, that it had puzzled the European phyſicians; and what had been ſold in the ſhops for it, is the root of a very different plant, and of a poiſonous nature.

The true root is called *mungus*, for the following reaſon.—There is a kind of weaſel in the Eaſt Indies, called *mungutia* by the natives, *mungo* by the Portugueſe, and *muncas* by the Dutch. This animal purſues the hooded ſerpent, as the cat does the mouſe with us. As ſoon as the ſerpent appears, the weaſel attacks him; and if ſhe chances to be bit by him, ſhe immediately runs to find a certain vegetable, upon eating which, ſhe returns, and renews the fight.—The Indians are of opinion that this plant is the mungos.

That celebrated traveller Kæmpfer, who kept one of theſe weaſels tame, that ate with him, lived with him, and was his companion wherever he went, ſays he ſaw one of theſe battles between her and the ſerpent, but could not certainly find out what root the weaſel looked out for. But whether the weaſel firſt diſcovered this antidote or not, it is an infallible remedy againſt the bite of the hooded ſerpent. And this he undertakes to aſcertain.

OPHIOXYLON, in botany: A genus of the monœcia order, belonging to the polygamia claſs of plants; and in the natural method ranking with thoſe of which the order is doubtful. The hermaphrodite calyx is quinquefid; the corolla quinquefid and funnel-ſhaped; with a cylindrical nectarium within its mouth.

Different hypotheſes reſpecting the ſituation of Ophir.

OPHIR, a country mentioned in Scripture, from which Solomon had great quantities of gold brought home in ſhips which he ſent out for that purpoſe; but where to fix its ſituation is the great difficulty, authors running into various opinions on that head. Some have gone to the Weſt, others to the Eaſt Indies, and the eaſtern coaſts of Africa, in ſearch of it.—Mr Bruce the celebrated Abyſſinian traveller has diſplayed much learning and ingenuity in ſettling this queſtion of Biblical hiſtory. To the ſatisfaction of moſt of his readers he has determined Ophir to be Sofala, a kingdom of Africa, on the coaſt of Moſembique, near Zanguebar (ſee SOFALA). His reaſons for this determination are ſo generally known, that it would be improper to repeat them here at length; becauſe ſuch as are not already acquainted with them may conſult his book, which has been long in the hands of the public. He juſtly obſerves, that in order to come to a certainty where this Ophir was, it will be neceſſary to examine what Scripture ſays of it, and to keep preciſely to every thing like deſcription which we can find there, without indulging our fancy farther. 1*ſt*, Then, the trade to Ophir was carried on from the Elanitic gulf through the Indian ocean. 2*dly*, The returns were gold, ſilver, and ivory, but eſpecially ſilver †. 3*dly*, The time of the going and coming of the fleet was preciſely three years ‡, at no period more nor leſs.

2
Hypotheſis of Mr Bruce

Now, if Solomon's fleet ſailed from the Elanitic gulf to the Indian ocean, this voyage of neceſſity muſt have been made by monſoons, for no other winds reign in that ocean. And what certainly ſhows this was the caſe, is the preciſe term of three years in which the fleet went and came between Ophir and Ezion-gaber.

Theſe mines of Ophir were probably what furniſhed the Eaſt with gold in the earlieſt times: great traces of excavation muſt therefore have appeared.

But John dos Santos ſays, that he landed at Sofala in the year 1586; that he ſailed up the great river Cuama as far as Tete, where, always deſirous to be in the neighbourhood of gold, his order had placed their convent. Thence he penetrated for above 200 leagues into the country, and ſaw the gold mines then working at a mountain called *Aſura*. At a conſiderable diſtance from theſe are the ſilver mines of Chicoua; at both places there is a great appearance of ancient excavations; and at both places the houſes of the kings are built with mud and ſtraw, whilſt there are large remains of maſſy buildings of ſtone and lime.

Arguments in ſupport of it.

Every thing then conſpires to fix the Ophir of Solomon in the kingdom of Sofala, provided it would neceſſarily require neither more nor leſs than three years to make a voyage from Ezion-gaber to that place and Tarſhiſh and return. To eſtabliſh this important fact, our author obſerves, that the fleet or ſhip for Sofala, parting in June from Ezion-gaber (ſee EZION-GABER), would run down before the northern monſoon to Mocha (ſee MOCHA). Here, not the monſoon, but the direction of the gulf, changes; and the violence of the ſouth-weſters, which then reign in the Indian ocean, make themſelves at times felt even in Mocha roads. The veſſel therefore comes to an anchor in the harbour of Mocha; and here ſhe waits for moderate weather and a fair wind, which carries her out of the ſtraits of Babelmandel, through the few leagues where the wind is variable.

Her courſe from this is nearly ſouth-weſt, and ſhe meets at Cape Gardefan a ſtrong ſouth-weſter that blows directly in her teeth. Being obliged to return into the gulf, ſhe miſtakes this for a trade-wind; becauſe ſhe is not able to make her voyage to Mocha but by the ſummer monſoon, which carries her no farther than the ſtraits of Babelmandel, and then leaves her in the face of a contrary wind, a ſtrong current to the northward, and violent ſwell.

The attempting this voyage with ſails, in theſe circumſtances, was abſolutely impoſſible, as their veſſels went only before the wind: if it was performed at all, it muſt have been by oars; and great havock and loſs of men muſt have been the conſequence of the ſeveral trials.

At laſt, philoſop[illegible] obſervation, together with the unwearied perſeverance of man bent upon his own views and intereſt, removed theſe difficulties, and ſhowed the mariners of the Arabian gulf, that theſe periodical winds, which in the beginning they looked upon as invincible barriers to the trading to Sofala, when once underſtood, were the very means of performing this voy[illegible]ly and expeditiouſly.

The veſſel tra[illegible] to Sofala ſailed from the bottom of the Arabian gulf in ſummer, with the monſoon at north, which carried her to Mocha. There the monſoon failed her by the change of the direction of the gulf. The ſouth-weſt winds, which blow without Cape Gardefan in the Indian ocean, forced themſelves round the cape ſo as to be felt in the road of Mocha, and make it uneaſy riding there. But thoſe ſoon changed, the weather became moderate, and the veſſel, we ſuppoſe in the month of Auguſt, was ſafe at anchor under Cape Gardefan, where was the port which, many years afterwards, was called *Promontorium Aromatum*. Here the ſhip was obliged to ſtay all November, becauſe all theſe ſummer months the wind ſouth of the cape was a ſtrong ſouth-weſter, as hath been before ſaid, directly in the teeth of the voyage to Sofala. But this time was not laſt; part of the goods bought to be ready for the return was ivory, frankincenſe, and myrrh; and the ſhip was then at the principal mart for theſe.

---

† 1 Kings x. 22.

‡ 1 Kings, x. 22. 2 Chron. ix. 21.

Our author ſuppoſes, that in November the veſſel ſailed with the wind at north-eaſt, with which ſhe would ſoon have made her voyage: but off the coaſt of Melinda, in the beginning of December, ſhe there met an anomalous monſoon at ſouth-weſt, in our days firſt obſerved by Dr Halley, which cut off her voyage to Sofala, and obliged her to put into the ſmall harbour of Mocha, near Melinda, but nearer ſtill to Tarſhiſh, which we find here by accident, and which we think a ſtrong corroboration that we are right as to the reſt of the voyage. In the annals of Abyſſinia, it is ſaid that Amda Sion, making war upon that coaſt in the 14th century, in a liſt of the rebellious Mooriſh vaſſals, mentions the chief of Tarſhiſh as one of them, in the very ſituation where we have now placed him.

Solomon's veſſel, then, was obliged to ſtay at Tarſhiſh till the month of April of the ſecond year. In May, the wind ſet in at north-eaſt, and probably carried her that ſame month to Sofala. All the time ſhe ſpent at Tarſhiſh was not loſt, for part of her cargo was to be brought from that place; and ſhe probably bought, beſpoke, or left it there. From May of the ſecond year, to the end of that monſoon in October the veſſel could not ſtir; the wind was north-eaſt. But this time, far from being loſt, was neceſſary to the traders for getting in their cargo, which we ſhall ſuppoſe was ready for them.

The ſhip ſails on her return, in the month of November of the ſecond year, with the monſoon ſouth-weſt, which in a very few weeks would have carried her into the Arabian gulf. But off Moccha, near Melinda and Tarſhiſh, ſhe met the north-eaſt monſoon, and was obliged to go into that port and ſtay there till the end of that monſoon; after which a ſouth-weſter came to her relief in May of the third year. With the May monſoon ſhe ran to Mocha within the ſtraits, and was there confined by the ſummer monſoon blowing up the Arabian gulf from Suez, and meeting her. Here ſhe lay till that monſoon which in ſummer blows northerly from Suez, changed to a ſouth-eaſt one in October or November, and that very eaſily brought her up into the Elanitic gulf, the middle or end of December of the third year. She had no need of more time to complete her voyage, and it was not poſſible ſhe could do it in leſs.

Such is a very ſhort and imperfect abſtract of our author's reaſons for placing Ophir in Sofala. If it excite the curioſity of our readers to conſult his work, it will anſwer the purpoſe for which we have made it.

4 Another hypotheſis.

We are now to give another ingenious conjecture concerning the ſituation of Ophir and Tarſhiſh, with which we have been favoured by Dr Doig, the learned author of Letters on the Savage State addreſſed to Lord Kames.

This reſpectable writer holds that Ophir was ſomewhere on the weſt coaſt of Africa, and that Tarſhiſh was the ancient Bætica in Spain. His eſſay is not yet publiſhed; but he authorizes us to give the following abſtract of it: "The firſt time that *Ophir*, or rather *Aufir*, occurs in Scripture, is in Gen. x. 29. where the ſacred hiſtorian, enumerating the ſons of Joktan, mentions Aufir as one of them." According to his account, the deſcendants of thoſe 13 brothers ſettled all in a contiguous ſituation, from Meſha (the Mocha of the moderns) to Sepharah, a mountain of the eaſt. Moſes, as every one knows, denominates countries, and the inhabitants of countries, from the patriarch of whom thoſe inhabitants deſcended. In deſcribing the courſe of one of the branches of the river of paradiſe, the ſame Moſes informs us that it encompaſſed the whole land of Havilah, &c. which abounded with fine gold, bdellium, and the onyx ſtone; and this land had its name from Havilah the 12th ſon of the patriarch Jotkan. *Ophir* or *Aufir* was Havilah's immediate elder brother; and of courſe the deſcendants of the former, in all probability, fixed their habitation in the neighbourhood of thoſe of the latter. If, then, the land of Havilah abounded with gold and precious ſtones, the land of Ophir undoubtedly produced the very ſame articles.

5 The original Ophir not the Ophir of Solomon; of which

Here then we have the original Ophir; here was found the primary gold of Ophir; and here lay the Ophir mentioned in Job xi. 24. But as navigation was then in its infant ſtate, the native land of gold mentioned by Job muſt have been much nearer home than that to which the fleets of Solomon and Hiram made their triennial voyages. That ſeveral countries on the ſouth-eaſt coaſt of Africa abounded with gold long after the era of Job, is evident from the teſtimony of Herodotus, Strabo, Diodorus Siculus, Ptolemy, Pomponius Mela, &c.; but that in theſe countries the Ophir of Solomon could not be ſituated, is plain, becauſe his ſhips in the ſame voyage touched at Tarſhiſh, which lay in a very different quarter.

The Abyſſinian traveller has placed this *regio aurifera* in Sofala on the eaſtern coaſt of Africa, nearly oppoſite to the iſland of Madagaſcar. This hypotheſis was current a hundred years before he was born; but I am perſuaded (ſays our author) that it is not tenable. The Ophir of Solomon, in whatever part of Africa it lay, muſt have been well known, prior to his reign, both to the Phœnicians and the Edomites. Theſe people navigated that monarch's fleet, and therefore could be no ſtrangers to the port whither they were bound. That it was in Africa is certain; and that it was on the weſt coaſt of that immenſe peninſula, will appear more than probable, when we have aſcertained the ſituation of Tarſhiſh, and the uſual courſe of Phœnician navigation. To theſe objects, therefore, we ſhall now direct our inquiries.

6 Th ſituation muſt be aſcerta by di th Tarſhiſh.

"Javan, the fourth ſon of the patriarch Japhet, had four ſons, Eliſha, *Tarſhiſh*, Kittim, and Dodanim or Rodanim; among whoſe 'deſcendants were the iſles of the Gentiles divided.' The city of *Tarſus* on the coaſt of Cilicia, at once aſcertains the region colonized by the deſcendants of Tarſhiſh. But as much depends upon determining the poſition of this country, I ſhall endeavour (ſays the Doctor) to fix it with all poſſible preciſion.

"In the firſt place, I muſt beg leave to obſerve, that there is not a ſingle paſſage in any ancient author, ſacred or profane, that ſo much as alludes to any city, diſtrict, canton, or country, of the name of Tarſhiſh in the eaſtern parts of the world. The deſcendants of Javan, of whom Tarſhiſh was one, are agreed on all hands to have extended their ſettlements towards the north-weſt, i. e. into Aſia Minor, Italy, and Spain. The inhabitants of Tarſhiſh are everywhere in Scripture ſaid to be addicted to navigation and commerce, in which they ſeem to have been connected with the Tyrians and Phœnicians, †, who were always ſaid by the Jews to inhabit the iſles of the ſea. Indeed, in Hebrew geography, all the countries toward the north and weſt, which were divided from Judea by the ſea, were called the iſles of the ſea ‡. Thus Iſaiah: 'The burden of Tyre. Howl ye ſhips of Tarſhiſh, for it is laid waſte, ſo that there is no houſe, no entering in: from the land of Chittim it is revealed unto them. Be ſtill ye inhabitants of the iſle, thou whom the merchants of Zidon, that paſs over the ſea, have repleniſhed.' The land of Chittim was Macedonia, and often Greece, from which every one knows that the deſtruction of Tyre came; and that Tarſhiſh was not an unconcerned ſpectator of that deſtruction, is obvious from the ſame prophet, who proceeds to ſay ||. 'As at the report concerning Egypt, ſo ſhall they be ſorely pierced at the report concerning Tyre. Paſs over to Tarſhiſh; howl ye inhabitants of the iſle. Is this your joyous city? It appears likewiſe from Ezekiel *, that Tarſhiſh was the merchant with whom Tyre traded for ſilver, iron, tin, and lead, and that this trade was carried on in fairs.

† Pſ. xlviii. 7. lxxii. 10.

‡ Gen. ii. 26.

|| Iſ. xxiii. *paſſim.*

The original Tarſhiſh where ſituated.

"From all theſe paſſages, it ſeems to be evident, that the deſcendants of Tarſhiſh ſettled on the weſtern coaſt of Aſia Minor; that theſe people were addicted to navigation and commerce; that in the courſe of their traffic they were connected with the Tyrians and Phœnicians; that the commerce they carried on conſiſted of ſilver, iron, tin, and lead; that the people of Tarſhiſh were connected with Kittim and the iſles of the Gentiles, which are confeſſedly ſituated toward the north and weſt of Judea.

"But leaſt, after all, a fact ſo fully authenticated ſhould ſtill be called in queſtion, I ſhall add one proof more, which will place the matter beyond the reach of doubt and controverſy.

"When the prophet Jonah intended to flee from the preſence of the Lord, in order to avoid preaching at Nineveh, let us ſee where the peeviſh deſerter embarked. (Jonah i. 3.) "And Jonah roſe up to flee unto Tarſhiſh, from the preſence of the Lord, and went down to Joppa; and he found a ſhip going to Tarſhiſh, and he paid the fare thereof, and went down into it, to go with them into Tarſhiſh, from the preſence of the Lord.' Every body knows that Joppa or Japhah ſtood upon the ſhore of the Mediterranean; of courſe the fugitive prophet had determined to go to ſome very diſtant region weſtward, and by that means to get as far from Nineveh as poſſible."

This not the Tarſhiſh of Solomon.

Having thus proved to a demonſtration, that the original Tarſhiſh was a region on the weſtern coaſt of Aſia Minor, where either the patriarch of that name, or ſome of his immediate deſcendants, planted a colony, it remains to determine whether this was actually the country from which Solomon imported the vaſt quantities of ſilver mentioned by the ſacred hiſtorian. That it was not, our author frankly acknowledges; and therefore, ſays he, we muſt look out for Solomon's Tarſhiſh in ſome other quarter of the globe.

To pave the way for this diſcovery, he very juſtly obſerves, that it has at all times been a common practice to transfer the name of one country to another, in conſequence of ſome analogy or reſemblance between them. It has likewiſe often happened, that when a commodity was brought from a very diſtant country by a very diſtant people, the people to whom it was imported have taken it for granted that it was produced in the region from which it was immediately brought to them. Of the truth of this poſition no man acquainted with the Greek and Roman poets can for a moment entertain a doubt. Hence the *Aſſyrium amomum* of Virgil, and the *Aſſyrium malabathrum* of Horace, though theſe articles were the product not of Aſſyria but of India. The Jews, who were as little acquainted with foreign countries as the Greeks and Romans, had very probably the ſame notions with them reſpecting articles of commerce; and if ſo, they would undoubtedly ſuppoſe, that the ſilver ſold by the merchants of Tarſhiſh was the product of that country. When this miſtake came to be diſcovered, they very naturally transferred the name *Tarſhiſh* from the country of the merchants to that of the articles which they imported. Let us now, ſays our author, try if we cannot find out where that country was.

9 The name of one country transferred to another.

It has been already ſhown, by quotations from Iſaiah and Ezekiel, that the merchants of Tarſhiſh traded in the markets of Tyre with ſilver, iron, lead, and tin. To theſe authorities, we ſhall add another from Jeremiah: "Silver (ſays that prophet) ſpread into plates is brought from Tarſhiſh." "But in Spain (continues our learned diſſertator), all thoſe commodities were found in the greateſt abundance. All the ancient authors who deſcribe that region dwell with rapture on its ſilver mines. This fact is too generally known to need to be ſupported by authorities. Spain was then the region which furniſhed Solomon's traders with the immenſe maſs of ſilver he is ſaid to have imported. This was, one might ſay, the modern Tarſhiſh; and hence both Joſephus and Euſebius are poſitive that the poſterity of Tarſhiſh actually peopled that country. If this was an early opinion, as it certainly was, the Jews would of courſe denominate Spain from the patriarch in queſtion.

"I have ſhown above, that the inhabitants of Tarſhiſh were ſtrictly connected with the Kittim, or Grecians: I ſhall here produce an authority which will prove to a demonſtration that the Kittim had extended their commerce into that part of Africa now called Barbary.

"The prophet Ezekiel, (xxvii. 6.) deſcribing the ſplendour and magnificence of Tyre, tells us, 'that the company of the Aſhurites made her benches of ivory, brought from the iſles of Kittim.' In the firſt place, I muſt obſerve, that there is probably a ſmall error in the orthography of the word Aſhurim. This term is everywhere in Scripture tranſlated Aſſyrians, entertained any doubt concerning the ſame property in flint glaſs, the effect of which is three times as great as crown glaſs. One may obſerve, however, in theſe kinds of glaſs, ſomething of a proportion between the mean refraction and the diſperſion of rays, which may enable us to reconcile theſe ſurpriſing effects with other principles already known.

Here, however, M. Euler announces to us another diſcovery of the ſame M. Zeiher, no leſs ſurpriſing than the former, and which diſconcerted all his ſchemes for reconciling the above-mentioned phenomena. As the ſix kinds of glaſs mentioned in the above table were compoſed of nothing but minium and flint, M. Zeiher happened to think of mixing alkaline ſalts with them, in order to give the glaſs a conſiſtence more proper for dioptric uſes; when he was much ſurpriſed to find this mixture greatly diminiſhed the mean refraction, almoſt without making any change in the diſperſion. After many trials, he at length obtained a kind of glaſs greatly ſuperior to the flint glaſs of Mr Dollond, with reſpect to the conſtruction of teleſcopes; ſince it occaſioned three times as great a diſperſion of the rays as the common glaſs, at the ſame time that the mean refraction was only as 1.61 to 1.

M. Euler alſo gives particular inſtructions how to find both the mean and extreme refractive power of different kinds of glaſs; and particularly adviſes to make uſe of priſms with very large refracting angles, not leſs than 70°.

Notwithſtanding it evidently appeared, we may ſay, to almoſt all philoſophers, that Mr Dollond had made a real diſcovery of ſomething not comprehended in the optical principles of Sir Iſaac Newton, it did not appear ſo to Mr Murdoch. Upon this occaſion, he interpoſed in the defence, as he imagined, of Sir Iſaac Newton; maintaining, that Mr Dollond's poſitions, which, he ſays, he knows not by what miſhap have been deemed paradoxes in Sir Iſaac's theory of light, are really the neceſſary conſequences of it. He alſo endeavours to ſhow that Sir Iſaac might not be miſtaken in his account of the experiment above mentioned. But, admitting all that he advances in this part of his defence, Newton muſt have made uſe of a priſm with a much ſmaller refracting angle than, from his own account of his experiments, we have any reaſon to believe that he ever did make uſe of.

The fact probably was, that Sir Iſaac deceived himſelf in this caſe, by attending to what he imagined to be the clear conſequence of his other experiments; and though the light he ſaw was certainly tinged with colours, and he muſt have ſeen it to be ſo, yet he might imagine that this circumſtance aroſe from ſome imperfection in his priſms, or in the diſpoſition of them, which he did not think it worth his while to examine. It is alſo obſervable, that Sir Iſaac is not ſo particular in his deſcription of his priſms, and other parts of his apparatus, in his account of his experiment, as he generally is in other caſes; and therefore, probably, wrote his account of it from his memory only. In reality, it is no reflection upon Sir Iſaac Newton, who did ſo much, to ſay that he was miſtaken in this particular caſe, and that he did not make the diſcovery that Mr Dollond did; though it be great praiſe to Mr Dollond, and all thoſe perſons who contributed to this diſcovery, that they ventured to call in queſtion the authority of ſo great a man.

Mr Dollond, however, was not the only optician who had the merit of making this diſcovery; it had been made and applied to the ſame purpoſe by a private gentleman—Mr Cheſt of Cheſt hall. He had obſerved that priſms of flint glaſs gave larger ſpectrums than priſms of water when the mean refraction was the ſame in both, i. e. when the deviation of the refracted ray from the direction of the incident was the ſame. He tried priſms of other glaſs, and found ſimilar differences; and he employed the diſcovery in the ſame manner, and made achromatic experiments ſome time before Dollond. Theſe facts came out in a proceſs raiſed at the inſtance of Watkins optician at Charing-croſs, as alſo in a publication by Mr Ramſden optician. There is, however, no evidence that Dollond ſtole the idea from Mr Cheſt, or that they had not both claims to the diſcovery.

19
Diſcovery of Dr Robert Blair for this purpoſe.

Still the beſt refracting teleſcopes, conſtructed on the principles of Mr Dollond, are defective, on account of that colour which, by the aberration of the rays, they give to objects viewed through them, unleſs the object glaſs be of ſmall diameter. This defect men of genius and ſcience have laboured to remove, ſome by one contrivance and ſome by another. Father Boſcowich, to whom every branch of optics is much indebted, has, in his attempts for this purpoſe, diſplayed much ingenuity; but the philoſopher whoſe exertions have been crowned with moſt ſucceſs, and who has perhaps made the moſt important diſcovery in this branch of ſcience ſince the era of Newton, is Dr Robert Blair regius profeſſor of aſtronomy in the college of Edinburgh. By a judicious ſet of experiments ably conducted, he has proved, that the quality of diſperſing the rays in a greater degree than crown glaſs, is not confined to a few mediums, but is poſſeſſed by a great variety of fluids, and by ſome of theſe in a moſt extraordinary degree. He has ſhown, that although the greater refrangibility of the violet rays than of the red rays, when light paſſes from any medium whatever into a vacuum, may be conſidered as a law of nature; yet in the paſſages of light from one medium into another, it depends entirely on the qualities of the mediums which of theſe rays ſhall be the moſt refrangible, or whether there ſhall be any difference in their refrangibility. In order to correct the aberration ariſing from difference of refrangibility among the rays of light, he inſtituted a ſet of experiments, in the conducting of which he detected a very ſingular and important quality in the muriatic acid. In all the diſperſive mediums hitherto examined, the green rays, which are the mean refrangible in crown glaſs, were found among the leſs refrangible; but in the muriatic acid, theſe ſame rays were by him found to make a part of the more refrangible. This diſcovery led to complete ſucceſs in removing the great defect of optical inſtruments, viz that diſſipation or aberration of the rays which ariſe from their unequal refrangibility, and has hitherto rendered it impoſſible to converge all of them to one point either by ſingle or oppoſite refractions. A fluid, in which the particles of marine acid and metalline particles hold a due proportion, at the ſame time that it ſeparates the extreme rays of the ſpectrum much more than crown glaſs, refracts all the orders of the rays in the ſame proportion that glaſs does: and hence rays of all colours made to diverge by the refraction of the glaſs, may either be rendered parallel by a ſubſequent refraction made in the confine of the glaſs and this fluid; or, by weakening the refractive denſity of the fluid, the refraction which takes place in the confine of it and glaſs may be rendered as regular as reflexion, without the leaſt colour whatever. The Doctor has a teleſcope, not exceeding 15 inches in length, with a compound object glaſs of this kind, which equals in all reſpects, if it does not ſurpaſs, the beſt of Dollond's 42 inches long. Of this object glaſs a figure will be found in the third volume of the Tranſactions of the Royal Society of Edinburgh; and to that volume we muſt refer our readers for a full and perſpicuous account of the experiments which led to this diſcovery, as well as of the important purpoſes to which it may be applied.

20 Of the refraction of the atmoſphere.

We ſhall conclude the hiſtory of the diſcoveries concerning refraction, with ſome account of the refractions of the atmoſphere.—Tables of this have been calculated by Mr Lambert, with a view to correct the inaccuracies of geometrical obſervations of the altitudes of mountains. The obſervations of Mr Lambert, however, go upon the ſuppoſition that the refractive power of the atmoſphere is invariable: But this is by no means the caſe; and therefore his rules muſt be conſidered as true for the mean ſtate of the air only.

A moſt remarkable variety in the refractive power of the atmoſphere was obſerved by Dr Nettleton, near Halifax in Yorkſhire, which demonſtrates how little we can depend upon the calculated heights of mountains, when the obſervations are made with an inſtrument, and the refractive power of the air is to be allowed for. Being deſirous to learn, by obſervation, how far the mercury would deſcend in the barometer at any given elevation (for which there is the beſt opportunity in that hilly country), he propoſed to take the height of ſome of their higheſt hills; but when he attempted it, he found his obſervation ſo much diſturbed by refraction, that he could come to no certainty. Having meaſured one hill of a conſiderable height, in a clear day, and obſerved the mercury at the bottom and at the top, he found, according to that eſtimation, that about 90 feet or more were required to make the mercury fall $\frac{1}{10}$th of an inch; but afterwards, repeating the experiment on a cloudy day, when the air was rather groſs and hazy, he found the ſmall angles ſo much increaſed by refraction as to make the hill much higher than before. He afterwards frequently made obſervations at his own houſe, by pointing a quadrant to the tops of ſome neighbouring hills, and obſerved that they would appear higher in the morning before ſunriſe, and alſo late in the evening, than at noon in a clear day, by ſeveral minutes. In one caſe the elevations of the ſame hill differed more than 30 minutes. From this he infers, that obſervations made on very high hills, eſpecialy when viewed at a diſtance, and under ſmall angles, as they generally are, are probably uncertain, and not much to be depended upon.

M. Euler conſidered with great accuracy the refractive power of the atmoſphere, as affected by different degrees of heat and elaſticity; in which he ſhows, that its refractive power, to a conſiderable diſtance from the zenith, is ſufficiently near the proportion of the tangent of that diſtance, and that the law of refraction follows the direct ratio of the height of the barometer, and the inverſe ratio of the difference marked by the thermometer; but when ſtars are in the horizon, the changes are in a ratio ſomewhat greater than this, more eſpecially on account of the variation in the heat.

21 Mr Michell's opinion concerning the twinkling of the ſtars.

The cauſe of the twinkling of the ſtars is now generally acknowledged to be the unequal refraction of light, in conſequence of inequalities and undulations in the atmoſphere.

Mr Michell ſuppoſes that the arrival of fewer or more rays at one time, eſpecially from the ſmaller or the more remote fixed ſtars, may make ſuch an unequal impreſſion upon the eye, as may, at leaſt, have ſome ſhare in producing this effect; ſince it may be ſuppoſed, that even a ſingle particle of light is ſufficient to make a ſenſible impreſſion upon the organs of ſight; ſo that very few particles arriving at the eye in a ſecond of time, perhaps no more than three or four, may be ſufficient to make an object conſtantly viſible. For though the impreſſion may be conſidered as momentary, yet the perception occaſioned by it is of ſome duration. Hence, he ſays, it is not improbable that the number of the particles of light which enter the eye in a ſecond of time, even from Sirius himſelf (the light of which does not exceed that of the ſmalleſt viſible fixed ſtar, in a greater proportion than that of about 1000 to 1), may not exceed 3000 or 4000, and from ſtars of the ſecond magnitude they may, therefore, probably not exceed 100. Now the apparent increaſe and diminution of the light which we obſerve in the twinkling of the ſtars, ſeems to be repeated at not very unequal intervals, perhaps about four or five times in a ſecond. He therefore thought it reaſonable to ſuppoſe, that the inequalities which will naturally ariſe from the chance of the rays coming ſometimes a little denſer, and ſometimes a little rarer, in ſo ſmall a number of them as muſt fall upon the eye in the fourth or fifth part of a ſecond, may be ſufficient to account for this appearance. An addition of two or three particles of light, or perhaps a ſingle one, upon 20, eſpecially if there ſhould be an equal deficiency out of the next 20, would, he ſuppoſed, be very ſenſible, as he thought was probable from the very great difference in the appearance of ſtars, the light of which does not differ ſo much as is commonly imagined. The light of the middlemoſt ſtar in the tail of the Great Bear does not, he thinks, exceed the light of the very ſmall ſtar that is next to it in a greater proportion than that of about 16 or 20 to 1; and M. Bouguer found, that a difference in the light of objects of one part in 66 was ſufficiently diſtinguiſhable.

It will perhaps, he ſays, be objected, that the rays coming from Sirius are too numerous to admit of a ſufficient inequality ariſing from the common effect of chance ſo frequently as would be neceſſary to produce this effect, whatever might happen with reſpect to the ſmaller ſtars; but he obſerves, that, till we know what inequality is neceſſary to produce this effect, we can only gueſs at it one way or the other.

Since theſe obſervations were publiſhed, Mr Michell has entertained ſome ſuſpicion that the unequal denſity of light does not contribute to this effect in ſo great degree as he had imagined, eſpecially in conſequence of obſerving that even Venus does ſometimes twinkle. This he once obſerved her to do remarkably when was ſhe about 6 degrees high, though Jupiter, which was then about 16 degrees high, and was ſenſibly leſs luminous, did not twinkle at all. If, notwithſtanding the great number of rays which, no doubt, come to the eye from ſuch a ſurface as this planet preſents, its appearance be liable to be affected in this manner, it muſt be owing to ſuch undulations in the atmoſphere, as will probably render the effect of every other cauſe altogether inſenſible. The conjecture, however, has ſo much probability in it, that it well deſerved to be recited.

22 M. Muſchenbroek's opinion.

M. Muſchenbroek ſuſpects, that the twinkling of the ſtars ariſes from ſome affection of the eye, as well as the ſtate of the atmoſphere. For he ſays, that in Holland, when the weather is froſty, and the ſky very clear, the ſtars twinkle moſt manifeſtly to the naked eye, though not in teleſcopes; and ſince he does not ſuppoſe that there is any great exhalation, or dancing of the vapour at that time, he queſtions whether the vivacity of the light affecting the eye may not be concerned in the phenomenon.

But this philoſopher might very eaſily have ſatisfied himſelf with reſpect to this hypotheſis, by looking at the ſtars near the zenith, when the light traverſes but a ſmall part of the atmoſphere, and therefore might be expected to affect the eye the moſt ſenſibly. For he would not have perceived them to twinkle near ſo much, as they do near the horizon, when much more of their light is intercepted by the atmoſphere.

Some aſtronomers have lately endeavoured to explain the twinkling of the fixed ſtars by the extreme minuteneſs of their apparent diameter; ſo that they ſuppoſe the ſight of them is intercepted by every mote that floats in the air. But Mr Michell obſerves, that no object can hide a ſtar from us that is not large enough to exceed the apparent diameter of the ſtar, by the diameter of the pupil of the eye; ſo that if a ſtar was a mathematical point, the interpoſing object muſt ſtill be equal in ſize to the pupil of the eye: nay, it muſt be large enough to hide the ſtar from both eyes at the ſame time.

Beſides a variation in the quantity of light, a momentary change of colour has likewiſe been obſerved in ſome of the fixed ſtars. Mr Melville ſays, that when one looks ſtedfaſtly at Sirius, or any bright ſtar not much elevated above the horizon, its colour ſeems not to be conſtantly white, but appears tinctured, at every twinkling, with red and blue. This obſervation Mr Melville puts among his queries, with reſpect to which he could not entirely ſatisfy himſelf; and he obſerves, that the ſeparation of the colours by the refractive power of the atmoſphere is, probably, too ſmall to be perceived. But the ſuppoſition of Mr Michell above-mentioned will pretty well account for this circumſtance, though it may be thought inadequate to the former caſe. For the red and blue rays being much fewer than thoſe of the intermediate colours, and therefore much more liable to inequalities, from the common effect of chance, a ſmall exceſs or defect in either of them will make a very ſenſible difference in the colour of the ſtars.

§ 3. *Diſcoveries concerning the Reflection of Light*

23 Account of the diſcoveries of the ancients.

However much the ancients might have been miſtaken with regard to the nature of light, we find that they were acquainted with two very important obſervations concerning it; viz. that light is propagated in right lines, and that the angle of incidence is equal to the angle of reflection. Who it was that firſt made theſe important obſervations is not known. But indeed, important as they are, and the foundation of a great part of even the preſent ſyſtem of optics, it is poſſible that, if he were known, he might not be allowed to have any ſhare of merit, at leaſt for the *former* of them; the fact is ſo very obvious, and ſo eaſily aſcertained. As to the latter, that *the angle of incidence is equal to the angle of reflection*, it was probably firſt diſcovered by obſerving a ray of the ſun reflected from the ſurface of water, or ſome other poliſhed body; or from obſerving the images of objects reflected by ſuch ſurfaces. If philoſophers attended to this phenomenon at all, they could not but take notice, that, if the ray fell nearly perpendicular upon ſuch a ſurface, it was reflected near the perpendicular; and if it fell obliquely, it was reflected obliquely: and if they thought applying any kind of meaſures to theſe angles, however coarſe and imperfect, they could not but ſee that there was ſufficient reaſon to aſſert their equality. At the ſame time they could not but know that the incident and reflected rays were both in the ſame plane.

Ariſtotle was ſenſible that it is the reflection of light from the atmoſphere which prevents total darkneſs after the ſun ſets, and in places where he doth not ſhine in the day time. He was alſo of opinion, that rainbows, halos, and mock ſuns, were all occaſioned by the reflection of the ſun beams in different circumſtances by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he ſays, is not ſingle, as in a mirror; for each drop of rain is too ſmall to reflect a viſible image, but the conjunction of all the images is viſible.

24 Euclid's treatiſe of optics.

Without inquiring any farther into the nature of light or viſion, the ancient geometricians contented themſelves with deducing a ſyſtem of optics from the two obſervations mentioned above, viz. the rectilinear progreſs of light, and the equality of the angles of incidence and reflection. The treatiſe of optics which has been aſcribed to Euclid is employed about determining the apparent ſize and figure of objects, from the angle under which they appear, or which the extremities of them ſubtend at the eye, and the apparent place of the image of an object reflected from a poliſhed miror; which he fixes at the place where the reflected ray meets a perpendicular to the miror drawn through the object. But this work is ſo imperfect, and ſo inaccurately drawn up, that it is not generally thought to be the production of that great geometrician.

25 Of the burning glaſſes of the ancients.

It appears from a circumſtance in the hiſtory of Socrates, that the effects of burning glaſſes had alſo been obſerved by the ancients; and it is probable that the Romans had a method of lighting their ſacred fire by means of a concave ſpeculum. It ſeems indeed to have been known pretty early, that there is an increaſe of heat in the place where the rays of light meet, when they are reflected from a concave mirror. The burning power of concave mirrors is taken notice of by Euclid in the ſecond book of the treatiſe abovementioned. If we give but a ſmall degree of credit to what ſome ancient hiſtorians are ſaid to have written concerning the exploits of Archimedes, we ſhall be induced to think that he made great uſe of this principle, in conſtructing ſome very powerful burning mirrors: but nothing being ſaid of other perſons making uſe of his inventions, the whole account is very doubtful. It is allowed, however, that this eminent geometrician did write a treatiſe on the ſubject of burning mirrors, though it be not now extant.

Plate CCCLII.

B. Porta ſuppoſes that the burning mirrors of the ancients were of metal, in the form of a ſection of a parabola. It follows from the properties of this curve, that all the rays which fall upon it, parallel to its axis, will meet in the ſame point at the focus. Conſequently, if the vertex of the parabola be cut off, as in fig. 1. it will make a convenient burning mirror. In ſome drawings of this inſtrument the fruſtum is ſo ſmall, as to look like a ring. With an inſtrument of this kind, it is thought, that the Romans lighted their ſacred fire. Some have alſo thought that this was the form of the mirror with which Archimedes burnt the Roman fleet; uſing either a lens, to throw the rays parallel, when they had been brought to a focus; or applying a ſmaller parabolic mirror for this purpoſe, as is repreſented fig. 2. But Dechales ſhows, that it is impoſſible to convey any rays in a direction parallel to one another, except thoſe that come from the ſame point in the ſun's diſk.

26 Of ſeeing images in the air.

All this time, however, the nature of reflection was very far from being underſtood. Even Lord Bacon, who made much greater advances in natural philoſophy than his predeceſſors, and who pointed out the true method of improving it, was ſo far deceived with regard to the nature of reflection and refraction, that he ſuppoſed it poſſible to ſee the image reflected from a looking glaſs, without ſeeing the glaſs itſelf; and to this purpoſe he quotes a ſtory of Friar Bacon, who is reported to have apparently walked in the air between two ſteeples, and which was thought to have been effected by reflection from glaſſes while he walked upon the ground.

The whole buſineſs of ſeeing images in the air may be traced up to Vitellio; and what he ſaid upon the ſubject ſeems to have paſſed from writer to writer, with conſiderable additions, to the time of Lord Bacon. What Vitellio endeavours to ſhow is, that it is poſſible, by means of a cylindrical convex ſpeculum, to ſee the images of objects in the air, out of the ſpeculum, when the objects themſelves cannot be ſeen. But, if his deſcription of the apparatus requiſite for this experiment be attended to, it will be ſeen that the eye was to be directed towards the ſpeculum, which was placed within a room, while both the object and the ſpectator were without it. But though he recommends this obſervation to the diligent ſtudy of his readers, he has not deſcribed it in ſuch a manner as is very intelligible; and, indeed, it is certain, that no ſuch effect can be produced by a convex mirror. If he himſelf did make any trial with the apparatus that he deſcribes for this purpoſe, he muſt have been under ſome deception with reſpect to it.

B. Porta ſays, that this effect may be produced by a plane mirror only; and that an ingenious perſon may ſucceed in it: but his more particular deſcription of a method to produce this extraordinary appearance is by a plane mirror and a concave one combined.

Kircher alſo ſpeaks of the poſſibility of exhibiting theſe pendulous images, and ſuppoſes that they are reflected from the denſe air: and the moſt perfect and pleaſing deception depending upon the images in the air is one of which this writer gives a particular account in his *Ars Magna Lucis et Umbræ*, p. 783. In this caſe the image is placed at the bottom of a hollow poliſhed cylinder, by which means it appears like a real ſolid ſubſtance, ſuſpended within the mouth of the veſſel. In this manner, he ſays, he once exhibited a repreſentation of the aſcenſion of Chriſt; when the images were ſo perfect, that the ſpectators could not be perſuaded, but by attempting to handle them, that they were not real ſubſtances.

Among other amuſing things that were either invented or improved by Kircher, was the method of throwing the appearance of letters, and other forms of things, into a darkened room from without, by means of a lens and a plane mirror. The figures or letters were written upon the face of the mirror, and inverted, and the focus of the lens was contrived to fall upon the ſcreen or wall that received their images. In this manner, he ſays, that with the light of the ſun he could throw a plain and diſtinct image 500 feet.

27 Diſcoveries of Kepler.

It was Kepler who firſt diſcovered the true reaſon of the apparent places of objects ſeen by reflecting mirrors, as it depends upon the angle which the rays of light, iſſuing from the extreme part of an object, make with one another after ſuch reflections. In plane mirrors theſe rays are reflected with the ſame degree of inclination to one another that they had before their incidence; but he ſhows that this inclination is changed in convex and concave mirrors.

28. Of Mr Boyle.

Mr Boyle made ſome curious obſervations concerning the reflecting powers of differently coloured ſubſtances. Many learned men, he ſays, imagined that ſnow affects the eyes, not by a *borrowed*, but by a *native* light; but having placed a quantity of ſnow in a room, after which all foreign light was excluded, neither he nor any body elſe was able to perceive it. To try whether white bodies reflect more light than others, he held a ſheet of white paper in a ſun beam admitted into a darkened room; and obſerved that it reflected much more light than a paper of any other colour, a conſiderable part of the room being enlightened by it. Farther, To ſhow that white bodies reflect the rays outwards, he adds, that common burning glaſſes will not of a long time burn or diſcolour white paper. When he was a boy, he ſays, and took great pleaſure in making experiments with theſe glaſſes, he was much ſurpriſed at this remarkable circumſtance; and it ſet him very early upon gueſſing at the nature of whiteneſs, eſpecially as he obſerved that the image of the ſun was not ſo well defined upon white paper as upon black; and as, when he pu[illegible]k upon the paper, the moiſture would be quickly dried up, and the paper, which he could not burn before, would preſently take fire. He alſo found, that, by expoſing his hand to the ſun, with a thin black glove upon it, it would be ſuddenly and more conſiderably heated, than if he held his naked hand to the rays, or put on a glove of thin white leather.

To prove that black is the reverſe of white, with reſpect to its property of reflecting the rays of the ſun, he procured a large piece of black marble; and having got it ground into the form of a large ſpherical concave ſpeculum, he found that the image of the ſun reflected from it was far from offending or dazzling his eyes, as it would have done from another ſpeculum; and though this was large, he could not in a long time ſet a piece of wood on fire with it; though a far leſs ſpeculum, of the ſame form, and of a more reflecting ſubſtance, would preſently have made it flame.

To ſatisfy himſelf ſtill farther with reſpect to this ſubject, he took a broad and large tile; and having made one half of its ſurface white and the other black, he expoſed it to the ſummer ſun. And having let it lie there ſome time, he found, that while the whited part remained cool, the part that was black was grown very hot. For his farther ſatisfaction, he ſometimes left part of the tile of its native red; and, after expoſing the whole to the ſun, obſerved that this part grew hotter than the white, but was not ſo hot as the black part. He alſo obſerves, that rooms hung with black are not only darker than they would otherwiſe be, but warmer too; and he knew ſeveral perſons, who found great inconvenience from rooms hung with black. As another proof of his hypotheſis, he informs us, that a virtuoſo, of unſuſpected credit, acquainted him, that, in a hot climate, he had ſeen eggs well roaſted in a ſhort time, by firſt blacking the ſhells, and then expoſing them to the ſun.

29
Of the infuſion of lignum nephriticum.

We have already taken notice of the remarkable property of lignum nephriticum firſt obſerved by Kircher. (See Guilandina.) However, all his obſervations with regard to it fell very ſhort of Mr Boyle. He deſcribes this lignum nephriticum to be a whitiſh kind of wood, that was brought from Mexico, which the natives call *coatl* or *tlapazatli*, and which had been thought to tinge water of a green colour only; but he ſays that he found it to communicate all kinds of colours. If, ſays he, an infuſion of this wood be put into a glaſs globe, and expoſed to a ſtrong light, it will be as colourleſs as pure water; but if it be carried into a place a little ſhaded, it will be a moſt beautiful green. In a place ſtill more ſhaded, it will incline to red; and in a very ſhady place, or in an opaque veſſel, it will be green again.

A cup of this remarkable wood was ſent to Kircher by the procurator of his ſociety at Mexico, and was preſented by him to the emperor as a great curioſity. It is called *lignum nephriticum*, becauſe the infuſion of it was imagined to be of ſervice in diſeaſes of the kidneys and bladder, and the natives of the country where it grows do make uſe of it for that purpoſe.

Mr Boyle corrected ſeveral of the haſty obſervations of Kircher concerning the colours that appear in the infuſion of lignum nephriticum, and he diverſified the experiments with it in a very pleaſing manner. He firſt diſtinctly noted the two very different colours which this remarkable tincture exhibits by tranſmitted and reflected light. If, ſays he, it be held directly between the light and the eye, it will appear tinged (excepting the very top of it, where a ſky coloured circle ſometimes appears) almoſt of a golden colour, except the infuſion be too ſtrong; in which caſe it will be dark or reddiſh, and requires to be diluted with water. But if it be held from the light, ſo that the eye be between the light and the phial, it will appear of a deep lively blue colour; as will alſo the drops, if any lie on the outſide of the glaſs.

When a little of this tincture was poured upon a ſheet of white paper, and placed in a window where the ſun could ſhine upon it, he obſerved, that if he turned his back upon the ſun, the ſhadow of his pen, or any ſuch ſlender ſubſtance, projected upon the liquor, would not be all dark, like other ſhadows; but that part of it would be curiouſly coloured, the edge of it next the body being almoſt of a lively golden colour, and the more remote part blue. Theſe, and other experiments of a ſimilar nature, many of his friends, he ſays, beheld with wonder; and he remembered an excellent oculiſt, who accidentally meeting with a phial full of this liquor, and being unacquainted with this remarkable property of it, imagined, after he had viewed it a long time, that ſome new and ſtrange diſtemper had ſeized his eyes: and Mr Boyle himſelf acknowledges, that the oddneſs of this phenomenon made him very deſirous to find out the cauſe of it; and his inquiries were not altogether unſucceſsful.

Obſerving that this tincture, if it were too deep, was not tinged in ſo beautiful a manner, and that the impregnating virtue of the wood did, by being frequently infuſed in freſh water, gradually decay, he conjectured that the tincture contained much of the eſſential ſalt of the wood; and to try whether the ſubtle parts, on which the colour depended, were volatile enough to be diſtilled, without diſſolving their texture, he applied ſome of it to the gentle heat of a lamp furnace; but he found all that came over was as limpid and colourleſs as rock water, while that which remained behind was of ſo deep a blue, that it was only in a very ſtrong light that it appeared of any colour.

Suſpecting that the tinging particles abounded with ſalts, whoſe texture, and the colour thence ariſing, would probably be altered by acids, he poured into a ſmall quantity of it a very little ſpirit of vinegar, and found that the blue colour immediately vaniſhed, while the golden one remained, on which ever ſide it was viewed with reſpect to the light.

Upon this he imagined, that as the acid ſalts of the vinegar had been able to deprive the liquor of its blue colour, a ſulphureous ſalt, which is of a contrary nature, would deſtroy their effects; and having placed himſelf betwixt the window and the phial, and let fall into the ſame liquor a few drops of oil of tartar *per deliquium*, he found that it was immediately reſtored to its former blue colour, and exhibited all the ſame phenomena which it had done at the firſt.

Having ſometimes brought a round long-necked phial, filled with this tincture, into a darkened room, into which a beam of the ſun was admitted by a ſmall aperture; and holding the phial ſometimes near the ſun beams, and ſometimes partly in them and partly out of them, changing alſo the poſition of the glaſs, and viewing it from ſeveral parts of the room, it exhibited a much greater variety of colours than it did in an enlightened room. Beſides the uſual colours, it was red in ſome places and green in others, and within were intermediate colours produced by the different degrees and odd mixtures of light and ſhade.

It was not only in this tincture of lignum nephriticum that Mr Boyle obſerved the difference between reflected and tranſmitted light. He obſerved it even in gold, though no perſon explained the cauſe of theſe effects before Sir Iſaac Newton. He took a piece of leaf gold, and holding it betwixt his eye and the light, obſerved, that it did not appear of a golden colour, but of a greeniſh blue. He alſo obſerved the ſame change of colour by candle light; but the experiment did not ſucceed with a leaf of ſilver.

The conſtitution of the atmoſphere and of the ſea, we ſhall find, by obſervations made in later periods, to be ſimilar to that of this infuſion; for the blue rays, and others of a faint colour, do not penetrate ſo far into them as the red, and others of a ſtronger colour: but what this conſtitution is, which is common to them all, deſerves to be inquired into. For almoſt all other tinctures, and this of lignum nephriticum too, after ſome change made in it by Mr Boyle, as well as all other ſemi-tranſparent coloured ſubſtances, as glaſs, appear of the ſame hue in all poſitions of the eye. To increaſe or diminiſh the quantity makes no difference, but to make the colour deeper or more dilute.

30
Mr Boyle's account of the colours of thin plates.

The firſt diſtinct account of the colours exhibited by thin plates of various ſubſtances, are met with among the obſervations of Mr Boyle. To ſhow the chemiſts that colours may be made to appear or vaniſh, where there is no acceſſion or change either of the ſulphureous, the ſaline, or the mercurial principle of bodies, he obſerves, that all chemical eſſential oils, as alſo good ſpirit of wine, being ſhaken till they riſe in bubbles, appear of various colours; which immediately vaniſh when the bubbles burſt, ſo that a colourleſs liquor may be immediately made to exhibit a variety of colours, and loſe them in a moment, without any change in its eſſential principles. He then mentions the colours that appear in bubbles of ſoap and water, and alſo in turpentine. He ſometimes got glaſs blown ſo thin as to exhibit ſimilar colours; and obſerves, that a feather, of a proper ſhape and ſize, and alſo a black ribbon, held at a proper diſtance, between his eye and the ſun, ſhowed a variety of little rainbows, as he calls them, with very vivid colours, none of which were conſtantly to be ſeen in the ſame objects.

31
Dr Hooke's account of theſe colour

Much more pains were taken with this ſubject, and a much greater number of obſervations reſpecting it were made, by Dr Hooke. As he loved to give ſurpriſe by his diſcoveries, he promiſed, at a meeting of the ſociety on the 7th of March 1672, to exhibit, at their next meeting, ſomething which had neither reflection nor refraction, and yet was diaphanous. Accordingly, at the time appointed, he produced the famous coloured bubble of ſoap and water, of which ſuch admirable uſe was afterwards made by Sir Iſaac Newton, but which Dr Hooke and his contemporaries ſeem to have overlooked in Mr Boyle's treatiſe on colours, though it was publiſhed nine years before. It is no wonder that ſo curious an appearance excited the attention of that inquiſitive body, and that they ſhould deſire him to bring an account of it in writing at their next meeting.

By the help of a ſmall glaſs pipe, there were blown ſeveral ſmall bubbles, out of a mixture of ſoap and water; where it was obſervable, that, at firſt, they appeared white and clear; but that, after ſome time, the film of water growing thinner, there appeared upon it all the colours of the rainbow: Firſt, a pale yellow; then orange, red, purple, blue, green, &c. with the ſame ſeries of colours repeated; in which it was farther obſervable, that the firſt and laſt ſeries were very faint, and that the middlemoſt order or ſeries were very bright. After theſe colours had paſſed over the changes above-mentioned, the film of the bubble began to appear white again; and preſently, in ſeveral parts of this ſecond white film, there appeared ſeveral holes, which by degrees grew very big, ſeveral of them running into one another. After reciting other obſervations, which are not of much conſequence, he ſays it is ſtrange, that though both the encompaſſing and encompaſſed air have ſurfaces, yet he could not obſerve that they afforded either reflection or refraction, which all the other parts of the encompaſſed air did. This experiment, he ſays, at firſt ſight, may appear very trivial, yet, as to the finding out the nature and cauſe of reflection, refraction, colours, congruity and incongruity, and ſeveral other properties of bodies, he looked upon it as one of the moſt inſtructive. And he promiſed to conſider it more afterwards; but we do not find that ever he did; nor indeed is it to be much regretted, as we ſhall ſoon find this buſineſs in better hands. He adds, that that which gives one colour by reflection, gives another by trajection; not much unlike the tincture of lignum nephriticum.

Dr Hooke was the firſt to obſerve, if not to deſcribe, the beautiful colours that appear in thin plates of Muſcovy glaſs. Theſe he ſays, are very beautiful to the naked eye, but much more when they are viewed with a microſcope. With this inſtrument he could perceive that theſe colours were ranged in rings ſurrounding the white ſpecks or flaws in this thin ſubſtance, that the order of the colours were the very ſame as in the rainbow, and that they were often repeated ten times. But the colours, he ſays, were diſpoſed as in the outer bow, and not the inner. Some of them alſo were much brighter than others, and ſome of them very much broader. He alſo obſerved, that if there was a place where the colours were very broad, and conſpicuous to the naked eye, they might be made, by preſſing the place with the finger, to change places, and move from one part to another. Laſtly, He obſerved, that if great care be uſed, this ſubſtance may ſplit into plates of $\frac{1}{8}$ or $\frac{1}{6}$ of an inch in diameter, each of which will appear through a microſcope to be uniformly adorned with ſome one vivid colour, and that theſe plates will be found upon examination to be of the ſame thickneſs throughout.

As a fact ſimilar to this, but obſerved previous to it, we ſhall here mention that Lord Brereton, at a meeting of the Royal Society in 1666, produced ſome pieces of glaſs taken out of a window of a church, both on the north and on the ſouth ſide of it; obſerving, that they were all eaten in by the air, but that the piece taken from the ſouth ſide had ſome colours like thoſe of the rainbow upon it, which the others on the north ſide had not. This phenomenon has been frequently obſerved ſince, and in other circumſtances. It is not to be doubted, but that in all theſe caſes, the glaſs is divided into thin plates, which exhibit colours, upon the ſame principle with thoſe which Dr Hooke obſerved in the bubble of ſoap and water, and in the thin plate of glaſs, which we ſhall find more fully explained by Sir Iſaac Newton. With care the thin plates of the glaſs may be ſeparated, and the theory verified.

32 Why the ſtars are viſible by day at the bottom of a well.

An obſervation made by Otto Guericke, well explains the reaſon why ſtars are viſible at the bottom of a deep well. It is, ſays he, becauſe the light that proceeds from them is not overpowered by the rays of the ſun, which are loſt in the number of reflections which they muſt undergo in the pit, ſo that they can never reach the eye of a ſpectator at the bottom of it.

But of all thoſe who have given their attention to this ſubject of the reflection of light, none ſeems to have given ſuch ſatisfaction as M. Bouguer; and next to thoſe of Sir Iſaac Newton, his labours ſeem to have been the moſt ſucceſsful. The object of his curious and elaborate experiments was to meaſure the degrees of light, whether emitted, reflected, or refracted, by different bodies. They were originally occaſioned by an article of M. Mairan's in the Memoirs of the French Academy for 1721, in which the proportion of the light of the ſun at the two ſolſtices was ſuppoſed to be known; and his laudable attempt to verify what had been before taken for granted, ſuggeſted a variety of new experiments, and opened to him and to the world a new field of optical knowledge. His firſt production upon this ſubject was a treatiſe entitled *Eſſai d'Optique*, which was received with general approbation. Afterwards, giving more attention to this ſubject, he formed an idea of a much larger work, to which many more experiments were neceſſary: but he was prevented, by a variety of interruptions, from executing his deſign ſo ſoon as he had propoſed, and he had hardly completed it at the time of his death, in 1758; ſo that we are obliged to his friend M. de la Caille for the care of the publication. At length, however, it was printed at Paris in 1760, under the title of *Traité d'Optique*.

33 Diſcoveries of M. Bou-

At the entrance upon this treatiſe, we are induced to form the moſt pleaſing expectations from our author's experiments, by his account of the variety, the ſingular accuracy, and circumſpection, with which he made them; whereby he muſt, to all appearance, have guarded againſt every avenue to error, and particularly againſt thoſe objections to which the few attempts that had been made, of a ſimilar nature, before him had been liable. In order to compare different degrees of light, he always contrived to place the bodies from which it proceeded, or other bodies illuminated by them, in ſuch a manner as that he could view them diſtinctly at the ſame time; and he either varied the ſtances of theſe bodies, or modified their light in ſome other way, till he could perceive no difference between them. Then, conſidering their different diſtances, or the other circumſtances by which their light was affected, he calculated the proportion which they would have borne to each other at the ſame diſtance, or in the ſame circumſtances.

Plate CCCLII. fig. 3.

To aſcertain the quantity of light loſt by reflection, he placed the mirror, or reflecting ſurface, B, on which the experiment was to be made, truly upright; and having taken two tablets, of preciſely the ſame colour, or of an equal degree of whiteneſs, he placed them exactly parallel to one another at E and D, and threw light upon them by means of a lamp or candle, P, placed in a right line between them. He then placed himſelf ſo, that with his eye at A he could ſee the tablet E, and the image of the tablet D, reflected from the mirror B, at the ſame time; making them as it were, to touch one another. He then moved the candle along the line ED, ſo as to throw more or leſs light upon either of them, till he could perceive no difference in the ſtrength of the light that came to his eye from either of them. After this, he had nothing more to do than to meaſure the diſtances EP and DP; for the ſquares of thoſe diſtances expreſſed the degree in which the reflection of the mirror diminiſhed the quantity of light. It is evident, that if the mirror reflected all the rays it received, the candle P muſt have been placed at C, at an equal diſtance from each of the tablets, in order to make them appear equally illuminated; but becauſe much of the light is loſt in reflection, they can only be made to appear equally bright by placing the candle nearer the tablet D, which is ſeen by reflexion only.

Fig. 4.

To find how much light is loſt by oblique reflection, he took two equally poliſhed plates, D and E, and cauſed them to be enlightened by the candle P; and while one of them, D, was ſeen at A, by reflection from B, placed in a poſition oblique to the eye, the other, E, was ſo placed, as to appear contiguous to it; and removing the plate E, till the light which it reflected was no ſtronger than that which came from the image D, ſeen by reflection at B, he eſtimated the quantity of light that was loſt by this oblique reflection, by the ſquares of the diſtances of the two objects from the candle.

It need ſcarcely be added, that in theſe experiments all foreign light was excluded, that his eye was ſhaded, and that every other precaution was obſerved in order to make his concluſions unqueſtionable.

Fig. 5.

In order to aſcertain the quantity of light loſt by reflection with the greateſt exactneſs, M. Bouguer introduced two beams of light into a darkened room, as by the apertures P and Q; which he had ſo contrived, that he could place them higher and lower, and enlarge or contract them at pleaſure; and the reflecting ſurface (as that of a fluid contained in a veſſel) was placed horizontally at O, from whence the light coming through the hole P, was reflected to R, upon the ſcreen GH, where it was compared with another beam of light that fell upon S, through the hole Q; which he made ſo much leſs than P, as that the ſpaces S and R were equally illuminated; and by the proportion that the apertures P and Q bore to each other, he calculated what quantity of light was loſt by the reflection at O.

It was neceſſary, he obſerves, that the two beams of light PO and QS (which he uſually made 7 or 8 feet long) ſhould be exactly parallel, that they might come from two points of the ſky equally elevated above the horizon, and having preciſely the ſame intenſity of light. It was alſo neceſſary that the hole Q ſhould be a little higher than P, in order that the two images ſhould be at the ſame height, and near one another. It is no leſs neceſſary, he ſays, that the ſcreen CH be exactly vertical, in order that the direct and reflected beams may fall upon it, with the ſame inclination; ſince, otherwiſe, though the two lights were perfectly equal, they would not illuminate the ſcreen equally. This diſpoſition, he ſays, ſerves to anſwer another important condition in theſe experiments; for the direct ray QS muſt be of the ſame length with the ſum of the incident and reflected rays, PO and OR, in order that the quantity of light introduced into the room may be ſenſibly proportional to the ſizes of the apertures.

We ſhall now proceed to recite the reſult of the experiments which he made to meaſure the quantity of light that is loſt by reflection in a great variety of circumſtances; but we ſhall introduce them by the recital of ſome which were made previous to them on the diminution of light by reflection, and the tranſmiſſion of it to conſiderable diſtances through the air, by M. Buffon at the time that he was conſtructing his machine to burn at great diſtances, mentioned under the article *Burning Glaſs*.

34 Of M. Buffon.

Receiving the light of the ſun in a dark place, and comparing it with the ſame light of the ſun reflected by a mirror, he found that at ſmall diſtances, as four or five feet, about one half was loſt by reflection; as he judged by throwing two reflected beams upon the ſame place, and comparing them with a beam of direct light; for then the intenſity of them both ſeemed to be the ſame.

Having received the light at greater diſtances, as at 100, 200, and 300 feet, he could hardly perceive that it loſt any of its intenſity by being tranſmitted through ſuch a ſpace of air.

He afterwards made the ſame experiments with candles, in the following manner: He placed himſelf oppoſite to a looking glaſs, with a book in his hand, in a room perfectly dark; and having one candle lighted in the next room, at the diſtance of about 40 feet, he had it brought nearer to him by degrees, till he was juſt able to diſtinguiſh the letters of the book, which was then 24 feet from the candle. He then received the light of the candle, reflected by the looking glaſs, upon his book, carefully excluding all the light that was reflected from any thing elſe; and he found that the diſtance of the book from the candle, including the diſtance from the book to the looking glaſs (which was only half a foot) was in all 15 feet. He repeated the experiment ſeveral times, and always with nearly the ſame reſult; and therefore concluded, that the quantity of direct light is to that of reflected as 576 to 225; ſo that the light of five candles reflected from a plane mirror is about equal to that of two candles.

From theſe experiments it appeared, that more light was loſt by reflection of the candles than of the ſun, which M. Buffon thought was owing to this circumſtance that the light iſſuing from the candle diverges, and therefore falls more obliquely upon the mirror than the light of the ſun, the rays of which are nearly parallel.

Theſe experiments and obſervations of M. Buffon are curious; though it will be ſeen that they fall far ſhort of thoſe of M. Bouguer, both in extent and accuracy. We ſhall begin with thoſe which we made to aſcertain the difference in the quantity of light reflected by glaſs and poliſhed metal.

35 Mr Bouguer's diſcoveries concerning the reflection of glaſs and poliſhed metal.

Uſing a ſmooth piece of glaſs one line in thickneſs, he found, that when it was placed at an angle of 15 degrees with the incident rays, it reflected 628 parts of 1000 which fell upon it; at the ſame time that a metallic mirror, which he tried in the ſame circumſtances, reflected only 561 of them. At a leſs angle of incidence much more light was reflected: ſo that at an angle of three degrees the glaſs reflected 700 parts, and the metal ſomething leſs, as in the former caſe.

Trying the reflection of bodies that were not poliſhed, he found that a piece of white plaſter, placed at an angle of 75°, with the incident rays, reflected $\frac{1}{210}$ part of the light that is received from a candle nine inches from it. White paper, in the ſame circumſtances, reflected it the ſame proportion; but at the diſtance of three inches, they both reflected 150 parts of 1000 that were incident.

Proceeding to make farther obſervations on the ſubject of reflected light, he premiſes the two following theorems, which he demonſtrates geometrically. 1. When the luminous body is at an infinite diſtance, and its light is received by a globe, the ſurface of which has a perfect poliſh, and abſorbs no light, it reflects the light equally in all directions, provided it be received at a conſiderable diſtance. He only excepts the place where the ſhadow of the globe falls; but this, he ſays, is no more than a ſingle point, with reſpect to the immenſity of the ſpherical ſurface which receives its light.

2. The quantity of light reflected in one certain direction will always be exactly the ſame, whether it be reflected by a very great number of ſmall poliſhed hemiſpheres, by a leſs number of larger hemiſpheres, or by a ſingle hemiſphere, provided they occupy the ſame baſe, or cover the ſame ground plan.

The uſe he propoſes to make of theſe theorems is to aſſiſt him in diſtinguiſhing whether the light reflected from bodies be owing to the extinction of it within them, or whether the roughneſs or eminences which cover them have not the ſame effect with the ſmall poliſhed hemiſpheres above mentioned.

He begins with obſerving, that, of the light reflected from Mercury, $\frac{1}{4}$ at leaſt is loſt, and that probably no ſubſtances reflect more than this. The rays were received at an angle of $11\frac{1}{2}$ degrees of incidence, that is meaſured from the ſurface of the reflecting body, and not from the perpendicular, which, he ſays, is what we are from this place to underſtand whenever he mentions the angle of incidence.

36 Great difference in the reflective power of ſubſtances according to the angle of incidence.

The moſt ſtriking obſervations which he made with reſpect to this ſubject, are thoſe which relate to the very great difference in the quantity of light reflected at different angles of incidence. In general, he ſays, that reflection is ſtronger at ſmall angles of incidence, and weaker at large ones. The difference is exceſſive when the rays ſtrike the ſurface of tranſparent ſubſtances,

ſtances, with different degrees of obliquity; but it is almoſt as great in ſome opaque ſubſtances, and it was always more or leſs ſo in every thing that he tried. He found the greateſt inequality in black marble; in which he was aſtoniſhed to find, that with an angle of 3° 35′ of incidence, though not perfectly poliſhed, yet it reflected almoſt as well as quickſilver. Of 1000 rays which it received, it returned 600; but when the angle of incidence was 14 degrees, it reflected only 156: when it was 30, it reflected 51; and when it was 80, it reflected only 23.

Similar experiments made with metallic mirrors always gave the differences much leſs conſiderable. The greateſt was hardly ever an eighth or a ninth part of it, but they were always in the ſame way.

The great difference between the quantity of light reflected from the ſurface of water, at different angles of incidence, is truly ſurpriſing; but our author obſerves, that this difference was greater when the ſmalleſt inclinations were compared with thoſe which were near to a right angle. He ſometimes ſuſpected, that, at very ſmall angles of incidence, the reflection from water was even greater than from quickſilver. All things conſidered, he thought it was not quite ſo great, though it was very difficult to determine the preciſe difference between them. In very ſmall angles, he ſays, that water reflects nearly $\frac{3}{4}$ of the direct light.

There is no perſon, he ſays, but has ſometimes felt the force of this ſtrong reflection from water, when he has been walking in ſtill weather on the brink of a lake oppoſite to the ſun. In this caſe, the reflected light is $\frac{1}{3}$, $\frac{1}{2}$, or ſometimes a greater proportion of the light that comes directly from the ſun, which is an addition to the direct rays of the ſun that cannot fail to be very ſenſible. The direct light of the ſun diminiſhes gradually as it approaches the horizon, while the reflected light at the ſame time grows ſtronger: ſo that there is a certain elevation of the ſun, in which the united force of the direct and reflected light will be the greateſt poſſible, and this he ſays is 12 or 15 degrees.

On the other hand, the light reflected from water at great angles of incidence is extremely ſmall. Our author was aſſured, that, when the light was perpendicular, it reflected no more than the 37th part that quickſilver does in the ſame circumſtances; for it did not appear, from all his obſervations, that water reflects more than the 60th, or rather the 55th, part of perpendicular light. When the angle of incidence was 50 degrees, the light reflected from the ſurface of water was about the 32d part of that which mercury reflected; and as the reflection from water increaſes with the diminution of the angle of incidence, it was twice as ſtrong in proportion at 39 degrees; for it was then the 16th part of the quantity that mercury reflected.

In order to procure a common ſtandard by which to meaſure the proportion of light reflected from various fluid ſubſtances, he pitched upon water as the moſt commodious; and partly by obſervation, and partly by calculation, which he always found to agree with his obſervations, he drew up the following table of the quantity of light reflected from the ſurface of water, at different angles with the ſurface.

Angles of incidence.	Rays reflected of 1000.	Angles of incidence.	Rays reflected of 1000.
$\frac{1}{2}$	721	17 $\frac{1}{2}$	178
1	692	20	145
1 $\frac{1}{2}$	669	25	97
2	639	30	65
2 $\frac{1}{2}$	614	40	34
5	501	50	22
7 $\frac{1}{2}$	409	60	19
10	333	70	18
12 $\frac{1}{2}$	271	80	18
15	211	90	18

In the ſame manner, he drew up the following table of the quantity of light reflected from the looking glaſs not quickſilvered.

Angles of incidence.	Rays reflected of 1000.	incidence	flected of 1000.
2 $\frac{1}{2}$	584	30	112
5	543	40	57
7 $\frac{1}{2}$	474	50	34
10	412	60	27
12 $\frac{1}{2}$	356	70	25
15	299	80	25
20	212	90	25
25	157		

Pouring a quantity of water into a veſſel containing quickſilver, it is evident that there will be two images of any object ſeen by reflection from them, one at the ſurface of the water, and the other at that of the quickſilver. In the largeſt angles of incidence, the image at the ſurface of the water will diſappear, which will happen when it is about a 60th or an 80th part leſs luminous than the image at the ſurface of the quickſilver. Depreſſing the eye, the image on the water will grow ſtronger, and that on the quickſilver weaker in proportion; till at laſt, the latter will be incomparably weaker than the former, and at an angle of about 10 degrees they will be equally luminous. According to the table, $\frac{333}{1000}$ of the incident rays are reflected from the water at this angle of 10 degrees. At the ſurface of the mercury they were reduced to 500; and of theſe, part being reflected back upon it from the under ſurface of the water, only 333 remained to make the image from the mercury.

37 Reflection of images by the air.

It has been obſerved by ſeveral perſons, particularly by Mr Edwards, (ſee Phil. Tranſ. Vol. LIII. p. 229.) that there is a remarkably ſtrong reflection into water, with reſpect to rays iſſuing from the water; and perſons under water have ſeen images of things in the air in a manner peculiarly diſtinct and beautiful: but this fact had not been obſerved with a ſufficient degree of attention, till it came into M. Bouguer's way to do it, and he acknowledges it to be very remarkable. In this caſe, he ſays, that from the ſmalleſt angles of incidence, to a certain number of degrees, the greateſt part of the rays are reflected, perhaps in as great a proportion as at the ſurface of metallic mirrors, or of quickſilver; while the other part, which does not eſcape into the air, is extinguiſhed or abſorbed; ſo that the ſurface of the tranſparent body appears opaque on the inſide. If the angle of incidence be increaſed only a few degrees, the ſtrong reflection ceaſes altogether, a great number of rays eſcape into the air, and very few are abſorbed or extinguiſhed. In proportion as the angle of incidence is farther increaſed, the quantity of the light reflected becomes leſs and leſs; and when it is near 90 degrees, almoſt all the rays eſcape out of the tranſparent body, its ſurface loſing almoſt all its power of reflection, and becoming almoſt as tranſparent as it is in other caſes, or when the light falls upon it from without.

38
Extinction of the rays of light at the ſurface of tranſparent bodies.

This property belonging to the ſurfaces of tranſparent bodies, of abſorbing or extinguiſhing the rays of light, is truly remarkable, and, as there is reaſon to believe, had not been noticed by any perſon before M. Bouguer. It had been conjectured by Sir Iſaac Newton that rays of light become extinct only by impinging upon the ſolid parts of bodies; but theſe obſervations of M. Bouguer ſhow that the fact is quite otherwiſe; and that this effect is to be attributed, not to the ſolid parts of bodies, which are certainly more numerous in a long tract of water than juſt in the paſſage out of water into air, but to ſome power lodged at the ſurfaces of bodies only, and therefore probably the ſame with that which reflects, refracts, and inflects the light.

39
Strong reflection by a priſm.

One of the above-mentioned obſervations, viz. all the light being reflected at certain angles of incidence from air into denſer ſubſtances, had frequently been made, eſpecially in glaſs priſms; ſo that Newton made uſe of one of them, inſtead of a reflecting mirror, in the conſtruction of his teleſcope. If a beam of light fall upon the air from within theſe priſms, at an angle of 10, 20, or 30 degrees, the effect will be nearly the ſame as at the ſurface of quickſilver, a fourth or a third of the rays being extinguiſhed, and $\frac{2}{3}$ or $\frac{3}{4}$ths reflected. This property retains its full force as far as an incidence of 49° 49′, (ſuppoſing the proportion of the ſines of the refraction to be 31 and 20 for the mean refrangible rays); but if the angle of incidence be increaſed but one degree, the quantity of light reflected inwards decreaſes ſuddenly, and a great part of the rays eſcape out of the glaſs, ſo that the ſurface becomes ſuddenly tranſparent.

All tranſparent bodies have the ſame property, with this difference, that the angle of incidence at which the ſtrong reflection ceaſes, and at which the light which is not reflected is extinguiſhed, is greater in ſome than in others. In water this angle is about 41° 32′; and in every medium it depends ſo much on the invariable proportion of the ſine of the angle of refraction to the ſine of the angle of incidence, that this law alone is ſufficient to determine all the phenomena of this new circumſtance, at leaſt as to this accidental opacity of the ſurface.

When our author proceeded to meaſure the quantity of light reflected by theſe internal ſurfaces at great angles of incidence, he found many difficulties, eſpecially on account of the many alterations which the light underwent before it came to his eye: but at length, uſing a plate of cryſtal, he found, that, at an angle of 75 degrees, this internal reflection diminiſhed the light 27 or 28 times; and as the external reflection at the ſame angle diminiſhed the light only 26 times, it follows that the internal reflection is a little ſtronger than the other.

Repeating theſe experiments with the ſame and different pieces of cryſtal, he ſometimes found the two reflections to be equally ſtrong; but, in general, the internal was the ſtronger. Alſo, the image reflected internally was always a little redder than an object which was ſeen directly through the plate of cryſtal.

40
Of the quantity of light reflected by different ſubſtances.

Reſuming his obſervations on the diminution of light, occaſioned by the reflection of opaque bodies obliquely ſituated, he compared it with the appearances of ſimilar ſubſtances which reflected the light perpendicularly. Uſing pieces of ſilver made very white, he found, that, when one of them was placed at an angle of 75 degrees with reſpect to the light, it reflected only 640 parts out of 1000. He then varied the angle, and alſo uſed white plaſter and fine Dutch paper, and drew up the following table of the proportion of the light reflected from each of thoſe ſubſtances at certain angles.

QUANTITY of LIGHT reflected from

Angles of incidence.	Silver.	Plaſter.	Dutch Paper.
90	1000	1000	1000
75	802	762	971
60	640	640	743
45	455	529	507
30	319	352	332
15	209	194	203

Suppoſing the aſperities of opaque bodies to conſiſt of very ſmall planes, it appears from theſe obſervations, that there are fewer of them in thoſe bodies which reflect the light at ſmall angles of incidence than at greater; and our author ſays, that the caſe was nearly the ſame with reſpect to all the opaque bodies that he tried. None of them had their roughneſs equivalent to ſmall hemiſpheres, which would have diſperſed the light equally in all directions; and, from the *data* in the preceding table, he deduces mathematically the number of the little planes that compoſe thoſe ſurfaces, and that are inclined to the general ſurface at the angles above-mentioned, ſuppoſing that the whole ſurface contains 1000 of them that are parallel to itſelf, ſo as to reflect the light perpendicularly, when the luminous body is ſituated at right angles with reſpect to it. His concluſions reduced to a table, correſponding to the preceding, are as follow:

Inclinations of the ſmall ſurfaces with reſpect to the large one.	The diſtribution of the ſmall planes that conſtitute the aſperities of the opaque ſurface in the		
	Silver.	Plaſter.	Paper.
0	1000	1000	1000
15	777	736	937
30	554	554	545
45	333	374	358
60	161	176	166
75	53	50	52

Theſe variations in the number of little planes, or ſurfaces, he expreſſes in the form of a curve; and afterwards he ſhows, geometrically, what would be the effect if the bodies were enlightened in one direction, and viewed in another; upon which ſubject he has ſeveral curious theorems and problems: as, the poſition of the eye being given, to find the angle at which the luminous body muſt be placed, in order to its reflecting the moſt light; or, the ſituation of the luminous body being given, to find a proper ſituation for the eye, in order to ſee the moſt enlightened, &c. But it would carry us too far into geometry to follow him through all theſe diſquiſitions.

41 Obſervations concerning the planets, &c.

Since the planets, as the accurate obſerver takes notice, are more luminous at their edges than at their centres, he concludes, from the above-mentioned principles, that the bodies which form them are conſtituted in a manner different from ours; particularly that their opaque ſurfaces conſiſt of ſmall planes, more of which are inclined to the general ſurface than they are in terreſtrial ſubſtances; and that there are in them an infinity of points, which have exactly the ſame ſplendour.

Our philoſopher and geometrician next proceeds to aſcertain the quantity of ſurface occupied by the ſmall planes of each particular inclination, from conſidering the quantity of light reflected by each, allowing thoſe that have a greater inclination to the common ſurface to take up proportionably leſs ſpace than thoſe which are parallel to it. And comparing the quantity of light that would be reflected by ſmall planes thus diſpoſed, with the quantity of light that was actually reflected by the three ſubſtances above-mentioned, he found that plaſter, notwithſtanding its extreme whiteneſs, abſorbs much light; for that, of 1000 rays that fall upon it, of which 166 or 167 ought to be reflected at an angle of 77 degrees, only 67 are in fact returned; ſo that 100 out of 167 were extinguiſhed, that is, about three-fifths.

With reſpect to the planets, our author concludes, that of 300,000 rays which the moon receives, 172,000 are abſorbed, or perhaps 204,100.

42 Of the ſurfaces of bodies.

Having conſidered the ſurfaces of bodies as conſiſting of planes only, he thus explains himſelf.—Each ſmall ſurface, ſeparately taken, is extremely irregular, and ſome of them are really concave, and others convex; but, in reducing them to a middle ſtate, they are to be conſidered as planes. Nevertheleſs he conſiders them as planes only with reſpect to the reception of the rays; for as they are almoſt all curves, and as, beſides this, many of thoſe whoſe ſituation is different from others contribute to the ſame effect, the rays always iſſue from an actual or imaginary focus, and after reflection always diverge from another.

If it be aſked, what becomes of thoſe rays that are reflected from one aſperity to another? he ſhows that very few of the rays can be in thoſe circumſtances; ſince they muſt fall upon planes which have more than 45 degrees of obliquity to the ſurface, of which there are very few in natural bodies. Theſe rays muſt alſo fall at the bottom of thoſe planes, and muſt meet with other planes ſimilarly ſituated to receive them; and conſidering the great irregularity of the ſurfaces of opaque bodies, it may be concluded that very few of the rays are thus reflected upon the body itſelf; and that the little that is ſo reflected is probably loſt to the ſpectators, being extinguiſhed in the body.

43 Mr Melville's obſervations on the manner in which bodies are heated by light.

We are obliged to Mr Melville for ſome ingenious obſervations on the manner in which bodies are heated by light. He obſerves, that, as each colorific particle of an opaque body muſt be ſomewhat moved by the reflection of the particles of light, when it is reflected backwards and forwards between the ſame particles, it is manifeſt that they muſt likewiſe be agitated with a vibratory motion, and the time of a vibration will be equal to that which light takes up in moving from one particle of a body to another adjoining. This diſtance, in the moſt ſolid opaque bodies, cannot be ſuppoſed greater than $\frac{1}{12500}$th of an inch, which ſpace a particle of light deſcribes in the $\frac{1}{125000000000000}$th of a ſecond. With ſo rapid a motion, therefore, may the internal parts of bodies be agitated by the influence of light, as to perform 125,000,000,000,000 vibrations, or more, in a ſecond of time.

The arrival of different particles of light at the ſurface of the ſame colorific particle, in the ſame or different rays, may diſturb the regularity of its vibrations, but will evidently increaſe their frequency, or raiſe ſtill ſmaller vibrations among the parts which compoſe thoſe particles; by which means the inteſtine motion will become more ſubtle, and more thoroughly diffuſed. If the quantity of light admitted into the body be increaſed, the vibrations of the particles muſt likewiſe increaſe in magnitude and velocity, till at laſt they may be ſo violent, as to make all the component particles daſh one another to pieces by their mutual colliſion; in which caſe, the colour and texture of the body muſt be deſtroyed.

Since there is no reflection of light but at the ſurface of a medium, the ſame perſon obſerves, that the greateſt quantity of rays, though crowded into the ſmalleſt ſpace, will not of themſelves produce any heat. From hence it follows, that the portion of air which lies in the focus of the moſt potent ſpeculum, is not at all affected by the paſſage of light through it, but continues of the ſame temperature with the ambient air; though any opaque body, or even any tranſparent body denſer than air, when put in the ſame place, would be intenſely heated in an inſtant.

This conſequence, evidently flowing from the plaineſt and moſt certain principles, not ſeeming to have been rightly underſtood by many philoſophers, and even the ſilence of moſt phyſical writers concerning this paradoxical truth making it probable that they were unacquainted with it, he thought it worth his while to ſay ſomething in explication of it. He obſerves, that the eaſieſt way to be ſatisfied of the matter experimentally is, to hold a hair, or a piece of down, immediately above the focus of a lens or ſpeculum, or to blow a ſtream of ſmoke from a pipe horizontally over it; for if the air in the focus were hotter than the ſurrounding fluid, it would continually aſcend upon account of its rarefaction, and thereby ſenſibly agitate thoſe ſlender bodies. Or a lens may be ſo placed as to form its focus within a body of water, or ſome other tranſparent ſubſtance, the heat of which may be examined from time to time with a thermometer; but care muſt be taken, in this experiment, to hold the lens as near as poſſible to the tranſparent body, leſt the rays, by falling cloſer than ordinary on its ſurface, ſhould warm it more than the common ſunbeams (B).

To apply theſe obſervations to the explication of natural phenomena, he obſerves, that the atmoſphere is not much warmed by the paſſage of the ſun's light through it, but chiefly by its contact with the heated ſurface of the globe. This, he thought, furniſhed one very ſimple and plauſible reaſon why it is coldeſt in all climates on the tops of very high mountains; namely, becauſe they are removed to the greateſt diſtance from the general ſurface of the earth. For it is well known, that a fluid heated by its contact with a ſolid body, decreaſes in heat in ſome inverſe proportion to the diſtance from the body. He himſelf found, by repeated trials, that the heat of water in deep lakes decreaſes regularly from the ſurface downwards. But to have this queſtion fully determined, the temperature of the air in the valley and on the mountain top muſt be obſerved every hour, both night and day, and carefully compared together.

From this doctrine he thinks it reaſonable to ſuppoſe, that the heat produced by a given number of rays, in an opaque body of a given magnitude, muſt be greater when the rays are more inclined to one another, than when they are leſs ſo; for the direction of the vibrations raiſed by the action of the light, whether in the colorific particles, or thoſe of an inferior order, will more interfere with one another; from whence the inteſtine ſhocks and colliſions muſt increaſe. Beſides this, the colorific particles of opaque bodies being diſpoſed in various ſituations, perhaps, upon the whole, the rays will fall more directly on each, the more they are inclined to one another. Is not this, ſays he, the reaſon of what has been remarked by philoſophers, that the heat of the ſun's light, collected into a cone, increaſes in approaching the focus in a much higher proportion than according to its denſity? That the difference of the angle in which the rays fall on any particle of a given magnitude, placed at different diſtances from the focus, is but ſmall, is no proof that the phenomenon cannot be aſcribed to it; ſince we know not in what high proportion one or both the circumſtances now mentioned may operate. However, that it proceeds not from any unknown action of the rays upon one another, as has been inſinuated, is evident from this, that each particular ray, after paſſing through the focus, preſerves its own colour and its own direction, in the ſame manner as if it were alone.

44
Abbé Nollet's experiments with burning glaſſes.

The attempts of the Abbé Nollet to fire inflammable ſubſtances by the power of the ſolar rays collected in the foci of burning mirrors, have a near relation to the preſent ſubject. Conſidering the great power of burning mirrors and lenſes, eſpecially thoſe of late conſtruction, it will appear ſurpriſing that this celebrated experimental philoſopher ſhould not be able to fire any liquid ſubſtance. But though he made the trial with all the care imaginable on the 19th of February 1757, he was not able to do it either with ſpirit of wine, olive oil, oil of turpentine, or ether; and though he could fire ſulphur, yet he could not ſucceed with Spaniſh wax, roſin, black pitch, or ſuet. He both threw the focus of theſe mirrors upon the ſubſtances themſelves, and alſo upon the fumes that roſe from them; but all the effect was, that the liquor boiled, and was diſperſed in vapour or very ſmall drops, but would not take fire. When linen rags, and other ſolid ſubſtances, were moiſtened with any of theſe inflammable liquids, they would not take fire till the liquid was diſperſed in a copious fume; ſo that rags thus prepared were longer in burning than thoſe that were dry.

45
M. Beaume's experiments.

M. Beaume, who aſſiſted M. Nollet in ſome of theſe experiments, obſerved farther, that the ſame ſubſtances which were eaſily fired by the flame of burning bodies, could not be ſet on fire by the contact of the hotteſt bodies that did not actually flame. Neither ether nor ſpirit of wine could be fired with a hot coal, or even red hot iron, unleſs they were of a white heat. From theſe experiments our author concludes, that, ſuppoſing the electric matter to be the ſame thing with fire or light, it muſt fire ſpirit of wine by means of ſome other principle. The members of the academy Del Cimento had attempted to fire ſeveral of theſe ſubſtances, though without ſucceſs; but this was ſo early in the hiſtory of philoſophy, that nobody ſeems to have concluded, that, becauſe they failed in this attempt, the thing could not be done. However, the Abbé informs us, that he read an account of his experiments to the Royal Academy at Paris ſeveral years before he attended to what had been done by the Italian philoſophers.

46
Bodies which ſeem to touch one another are not in actual contact.

By the help of optical principles, and eſpecially by obſervations on the reflection of light, Mr Melville diſcovered that bodies which ſeem to touch one another are not always in actual contact. "It is common (ſays he) to admire the volubility and luſtre of drops of rain that lie on the leaves of colewort, and ſome other vegetables;" but no philoſopher, as far as he knew, had put himſelf to the trouble of explaining this curious phenomenon. Upon inſpecting them narrowly, he found that the luſtre of the drop is produced by a copious reflection of light from the flattened part of its ſurface contiguous to the plant. He obſerved farther, that, when the drop rolls along a part which has been wetted, it immediately loſes all its luſtre, the green plant being then ſeen clearly through it; whereas, in the other caſe, it is hardly to be diſcerned.

From theſe two obſervations put together, he concluded, that the drop does not really touch the plant, when it has the mercurial appearance, but is ſuſpended in the air at ſome diſtance from it by the force of a repulſive power. For there could not be any copious reflection of white light from its under ſurface, unleſs there were a real interval between it and the ſurface of the plant.

If that ſurface were perfectly ſmooth, the under ſurface of the drop would be ſo likewiſe, and would therefore ſhow an image of the illuminating body by reflection

---

(B) To theſe obſervations objections might be made, which it would not perhaps be eaſy to anſwer; but we are at preſent giving only the *hiſtory* of optics.

reflection, like a piece of poliſhed ſilver; but as it is conſiderably rough and unequal, the under ſurface becomes rough likewiſe, and ſo, by reflecting the light copiouſly in different directions, aſſumes the reſplendent white colour of unpoliſhed ſilver.

It being thus proved by an optical argument, that the drop is not really in contact with the plant which ſupports it, it may eaſily be conceived whence its volubility ariſes, and why it leaves no moiſture where it rolls.

47 Two curious miſcellaneous obſervations. Before we conclude the hiſtory of the obſervations concerning the reflection of light, we muſt not omit to take notice of two curious miſcellaneous ones. Baron Alexander Funk, viſiting ſome ſilver mines in Sweden, obſerved, that, in a clear day, it was as dark as pitch underground, in the eye of a pit, at 60 or 70 fathoms deep; whereas, in a cloudy or rainy day, he could even ſee to read at 106 fathoms deep. Inquiring of the miners, he was informed that this is always the caſe; and, reflecting upon it, he imagined that it aroſe from this circumſtance, that when the atmoſphere is full of clouds, light is reflected from them into the pit in all directions, and that thereby a conſiderable proportion of the rays are reflected perpendicularly upon the earth; whereas, when the atmoſphere is clear, there are no opaque bodies to reflect the light in this manner, at leaſt in a ſufficient quantity; and rays from the ſun itſelf can never fall perpendicularly in that country. The other was that of the ingenious Mr Grey, who makes ſuch a figure in the hiſtory of electricity. This gentleman took a piece of ſtiff brown paper, and pricking a ſmall hole in it, he held it at a little diſtance before him; when, applying a needle to his eye, he was ſurpriſed to ſee the point of it inverted. The nearer the needle was to the hole, the more it was magnified, but the leſs diſtinct; and if it was ſo held, as that its image was near the edge of the hole, its point ſeemed crooked. From theſe appearances he concluded, that theſe ſmall holes, or ſomething in them, produce the effects of concave ſpeculums; and from this circumſtance he took the liberty to call them *aërial ſpeculums*.

§ 4. *Diſcoveries concerning the Inflection of Light.*

This property of light was not diſcovered till about the middle of the laſt century. The perſon who firſt made the diſcovery was Father Grimaldi; at leaſt he firſt publiſhed an account of it in his treatiſe *De lumine, coloribus, et iride,* printed in 1666. Dr Hooke, however, laid claim to the ſame diſcovery, though he did not publiſh his obſervations till ſix years after Grimaldi; having probably never ſeen his performance.

48 Dr Hooke's diſcoveries. Dr Hooke having made his room completely dark, admitted into it a beam of the ſun's light by a very ſmall hole in a braſs plate fixed in the window-ſhutter. This beam ſpreading itſelf, formed a cone, the apex of which was in the hole, and the baſe was on a paper, ſo placed as to receive it at ſome diſtance. In this image of the ſun, thus painted on the paper, he obſerved that the middle was much brighter than the edges, and that there was a kind of dark penumbra about it, of about a 16th part of the diameter of the circle; which penumbra, he ſays, muſt be aſcribed to a property of light, which he promiſed to explain.—Having obſerved this, at the diſtance of about two inches from the former he let in another cone of light; and receiving the baſes of them, at ſuch a diſtance from the holes as that the circles interſected each other, he obſerved that there was not only a penumbra, or darker ring, encompaſſing the lighter circle, but a manifeſt dark line, or circle, which appeared even where the limb of the one interfered with that of the other. This appearance is diſtinctly repreſented, fig. 6. Plate CCLII.

Comparing the diameter of this baſe with its diſtance from the hole, he found it to be by no means the ſame as it would have been if it had been formed by ſtraight lines drawn from the extremities of the ſun's diſk, but varied with the ſize of the holes, and the diſtance of the paper.

Struck with this appearance, he proceeded to make farther experiments concerning the nature of light thus tranſmitted. To give a juſt idea of which he held an opaque body BB, fig. 7. ſo as to intercept the light that entered at a hole in the window ſhutter O, and was received on the ſcreen AP. In theſe circumſtances, he obſerved, that the ſhadow of the opaque body (which was a round piece of wood, not bright or poliſhed) was all over ſomewhat enlightened, but more eſpecially towards the edge. Some perſons who were preſent, imagining that this light within the ſhadow might be produced by ſome kind of reflection from the ſide of this opaque body, on account of its roundneſs; and others ſuppoſing it might proceed from ſome reflection from the ſides of the hole in the piece of braſs through which the light was admitted into the room; to obviate both theſe objections, he admitted the light through a hole burnt in a piece of paſteboard, and intercepted it with a razor which had a very ſharp edge; but ſtill the appearances were the very ſame as before: ſo that, upon the whole, he concluded that they were occaſioned by a new property of light, different from any that had been obſerved by preceding writers.

He farther diverſified this experiment, by placing the razor ſo as to divide the cone of light into two parts, the hole in the ſhutter remaining as before, and placing the paper ſo as that none of the enlightened part of the circle fell upon it, but only the ſhadow of the razor; and, to his great ſurpriſe, he obſerved what he calls a *very briſk and viſible radiation* ſtriking down upon the paper, of the ſame breadth with the diameter of the lucid circle; and this radiation always ſtruck perpendicularly from the line of ſhadow, and, like the tail of a comet, extended more than 10 times, and probably more than 100 times the breadth of the remaining part of the circle: nay, as far as he could find, by many trials, the light from the edge ſtruck downwards into the ſhadow very near to a quadrant, though the greater were the deflections of this new light from the direct radiations of the cone, the more faint they were.

Obſerving this appearance with more attention, he found, wherever there was a part of the interpoſed body higher than the reſt, that, oppoſite to it, the radiation of light into the ſhadow was brighter, as in the figure; and wherever there was a notch or gap in it, there would be a dark ſtroke in the half-enlightened ſhadow. From all theſe appearances, he concluded, that they were to be aſcribed to a new property of light, whereby it is deflected from ſtraight lines, contrary to what had been before aſſerted by optical writers.

It does not appear, however, that our philoſopher ever proſecuted this experiment to any purpoſe; as all that we find of his on the ſubject of light, after this time, are ſome crude thoughts which he read at a meeting of the Royal Society, on the 18th of March 1675; which, however, as they are only ſhort hints, we ſhall copy.

They conſiſt of eight articles; and, as he thought, contained an account of ſeveral properties of light that had not been noticed before. There is a deflection of light, differing both from reflection and refraction, and ſeeming to depend on the unequal denſity of the conſtituent parts of the ray, whereby the light is diſperſed from the place of condenſation, and rarefied, or gradually diverged into a quadrant. 2. This deflection is made towards the ſuperficies of the opaque body perpendicularly. 3. Thoſe parts of the diverged radiations which are deflected by the greateſt angle from the ſtraight or direct radiations are the fainteſt, and thoſe that are deflected by the leaſt angles are the ſtrongeſt. 4. Rays cutting each other in one common foramen do not make the angles at the vertex equal. 5. Colours may be made without refraction. 6. The diameter of the ſun cannot be truly taken with common ſights. 7. The ſame rays of light, falling upon the ſame point of an object, will turn into all ſorts of colours, by the various inclinations of the object. 8. Colours begin to appear when two pulſes of light are blended ſo well, and ſo near together, that the ſenſe takes them for one.

49
Grimaldi's
diſcoveries.
Plate
CCCLII.

We ſhall now proceed to the diſcoveries of Father Grimaldi. Having introduced a ray of light, through a very ſmall hole, AB, fig. 8. into a darkened room, he obſerved that the light was diffuſed in the form of a cone, the baſe of which was CD; and that if any opaque body, FE, was placed in this cone of light, at a conſiderable diſtance from the hole, and the ſhadow was received upon a piece of white paper, the boundaries of it were not confined within GH, or the penumbra IL, occaſioned by the light proceeding from different parts of the aperture, and of the diſk of the ſun, but extended to MN; at which he was very much ſurpriſed, ſuſpecting, and finding by calculation, that it was conſiderably broader than it could have been made by rays paſſing in right lines by the edges of the object.

But the moſt remarkable circumſtance in this appearance was, that upon the lucid part of the baſe, CM and ND, ſtreaks of coloured light were plainly diſtinguiſhed, each being terminated by blue on the ſide next to the ſhadow, and by red on the other; and though theſe coloured ſtreaks depended, in ſome meaſure, on the ſize of the aperture AB, becauſe they could not be made to appear if it was large, yet he found that they were not limited either by it, or by the diameter of the ſun's diſk.

He farther obſerved, that theſe coloured ſtreaks were not all of the ſame breadth, but grew narrower as they receded from the ſhadow, and were each of them broader the farther the ſhadow was received from the opaque body, and alſo the more obliquely the paper on which they were received was held with reſpect to it. He never obſerved more than three of theſe ſtreaks.

To give a clearer idea of theſe coloured ſtreaks, he drew the repreſentation of them, exhibited in fig. 9. in which NMO repreſents the broadeſt and moſt luminous ſtreak, next to the dark ſhadow X. In the ſpace in which M is placed there was no diſtinction of colour, but the ſpace NN was blue, and the ſpace OO, on the other ſide of it, was red. The ſecond ſtreak, QPR was narrower than the former; and of the three parts of which it conſiſted, the ſpace P had no particular colour, but QQ was a faint blue, and RR a faint red. The third ſtreak, TSV, was exactly ſimilar to the two others, but narrower than either of them, and the colour ſtill fainter.

Theſe coloured ſtreaks he obſerved to lie parallel to the ſhadow of the opaque body; but when it was of an angular form, they did not make the ſame acute angles, but were bent into a curve, the outermoſt being rounder than thoſe that were next the ſhadow, as is repreſented in fig. 10. If it was an inward angle, as DCH, the coloured ſtreaks, parallel to each other of the two ſides croſſed without obliterating one another; only the colours were thereby rendered either more intenſe or mixed.

The light that formed theſe coloured ſtreaks, the reader will perceive, muſt have been bent from the body; but this attentive obſerver has likewiſe given an account of other appearances, which muſt have been produced by the light bending towards the body. For within the ſhadow itſelf he ſometimes perceived coloured ſtreaks, ſimilar to thoſe above mentioned on the outſide of the ſhadow. Sometimes he ſaw more of them, and ſometimes fewer; but for this purpoſe a very ſtrong light was requiſite, and the opaque body was obliged to be long, and of a moderate breadth; which, he ſays, is eaſily found by experience. A hair, for inſtance, or a fine needle, did not anſwer ſo well as a thin and narrow plate: and the ſtreaks were moſt diſtinguiſhable when the ſhadow was taken at the greateſt diſtance; but then the light grew fainter in the ſame proportion.

The number of theſe ſtreaks within the ſhadow was greater in proportion to the breadth of the plate. They were at leaſt two, and ſometimes four, if a thicker rod were made uſe of. But, with the ſame plate or rod, more or fewer ſtreaks appeared, in proportion to the diſtance at which the ſhadow was received; but they were broader when they were few, and narrower when there were more of them; and they were all much more diſtinct when the paper was held obliquely.

Theſe coloured ſtreaks within the ſhadow, like thoſe on the outſide of it, were bent in an arch, round the acute angles of the ſhadow, as they are repreſented in fig. 11. At this angle alſo, as at D, other ſhorter lucid ſtreaks were viſible, bent in the form of a plume, as they are drawn betwixt D and C, each bending round and meeting again in D. Theſe angular ſtreaks appeared, though the plate or rod was not wholly immerſed in the beam of light, but the angle of it only; and there were more or fewer in number in proportion to the breadth of the rod or plate. If the plate or rod was very thin, the coloured ſtreaks within the ſhadow might be ſeen to bend round from the oppoſite ſides, and meet one another as at B. A only repreſents a ſection of the figure, and not a proper termination of the ſhadow, and the ſtreaks within each ſide of it. The coloured ſtreaks without the ſhadow, he alſo obſerves, bend round it in the ſame manner.

Our author acknowledges, that he omits ſeveral obſervations of leſs conſequence, which cannot but occur to any perſon who ſhall make the experiment: and he ſays, that he was not able to give a perfectly clear idea of what he has attempted to deſcribe, nor does he think it in the power of words to do it.

Plate CCCLII.

In order to obtain the more ſatisfactory proof that rays of light do not always proceed in ſtraight lines, but really bend, in paſſing by the edges of bodies, he diverſified the firſt of the above-mentioned experiments in the following manner. He admitted a beam of light, by a very ſmall aperture, into a darkened room, as before; and, at a great diſtance from it, he fixed a plate EF, fig. 12. with a ſmall aperture, GH, which admitted only a part of the beam of light, and found, that when the light tranſmitted through this plate was received at ſome diſtance upon a white paper, the baſe IK was conſiderably larger than it could poſſibly have been made by rays iſſuing in right lines through the two apertures, as the other ſtraight lines drawn cloſe to their edges plainly demonſtrate.

That thoſe who chooſe to repeat theſe experiments may not be diſappointed in their expectations from them, our author gives the following more particular inſtructions. The ſun's light muſt be very intenſe, and the apertures through which it is tranſmitted very narrow, particularly the firſt, CD, and the white paper, IK, on which it is received, muſt be at a conſiderable diſtance from the hole GH; otherwiſe it will not much exceed NO, which would be the breadth of the beam of light proceeding in ſtraight lines. He generally made the aperture CD $\frac{4}{100}$ or $\frac{5}{100}$ part of an ancient Roman foot, and the ſecond aperture, GH, $\frac{25}{100}$ or $\frac{30}{100}$; and the diſtances DG and GN, were, at leaſt, 12 ſuch feet. The obſervation was made in the ſummer time, when the atmoſphere was free from all vapours, and about mid-day.

F. Grimaldi alſo made the ſame experiment that has been recited from Dr Hooke, in which two beams of light, entering a darkened room by two ſmall apertures near to one another, projected cones of light, which, at a certain diſtance, in part coincided; and he particularly obſerved that the dark boundaries of each of them were viſible within the lucid ground of the other.

50 Obſervation of Dechales.

To theſe diſcoveries of Grimaldi, we ſhall ſubjoin an additional obſervation of Dechales; who took notice, that if ſmall ſcratches be made in any piece of poliſhed metal, and it be expoſed to the beams of the ſun in a darkened room, it will reflect the rays ſtreaked with colours in the direction of the ſcratches; as will appear if the reflected light be received upon a piece of white paper. That theſe colours are not produced by refraction, he ſays, is manifeſt; for that, if the ſcratches be made upon glaſs, the effect will be the ſame; and in this caſe, if the light had been refracted at the ſurface of the glaſs, it would have been tranſmitted through it. From theſe, and many other obſervations, he concludes that colour does not depend upon the refraction of light only, nor upon a variety of other circumſtances, which he particularly enumerates, and the effects of which he diſcuſſes, but upon the intenſity of the light only.

51 Of M. de la Hire.

We ſhall here give an account of a phenomenon of viſion obſerved by M. de la Hire, becauſe the ſubject of this ſection, viz. the *inflection of light*, ſeems to ſupply the true ſolution of it, though the author himſelf thought otherwiſe. It is obſervable, he ſays, that when we look at a candle, or any luminous body, with our eyes nearly ſhut, rays of light are extended from it, in ſeveral directions, to a conſiderable diſtance, like the tails of comets. This appearance exerciſed the ſagacity of Deſcartes and Rohault, as well as of our author; but all three ſeem to have been miſtaken with reſpect to it. Deſcartes aſcribed this effect to certain wrinkles in the ſurface of the humours of the eye. Rohault ſays, that when the eye-lids are nearly cloſed, the edges of them act like convex lenſes. But our author ſays, that the moiſture on the ſurface of the eye, adhering partly to the eye itſelf, and partly to the edge of the eye-lid, makes a concave mirror, and ſo diſperſes the rays at their entrance into the eye. But the true reaſon ſeems to be, that the light paſſing among the eye-laſhes, in this ſituation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions. The two former of theſe opinions are particularly ſtated and objected to by our author.

52 Sir Iſaac Newton's diſcoveries.

The experiments of Father Grimaldi and Dr Hooke were not only repeated with the greateſt care by Sir Iſaac Newton, but carried much farther than they had thought of. So little uſe had been made of Grimaldi's obſervation, that all philoſophers before Newton had aſcribed the broad ſhadows, and even the fringes of light which he deſcribed, to the ordinary refraction of the air: but we ſhall ſee them placed in a very different point of view by our author.

Plate CCCLIII.

He made in a piece of lead a ſmall hole with a pin, the breadth of which was the 42d part of an inch. Through this hole he let into his darkened chamber a beam of the ſun's light; and found, that the ſhadows of hairs, and other ſlender ſubſtances placed in it, were conſiderably broader than they would have been if the rays of light had paſſed by thoſe bodies in right lines. He therefore concluded, that they muſt have paſſed as they are repreſented in fig. 1. in which X repreſents a ſection of the hair, and AD, BE, &c. rays of light paſſing by at different diſtances, and then falling upon the wall GQ. Since, when the paper which receives the rays is at a great diſtance from the hair, the ſhadow is broad, it muſt follow, as he obſerves, that the hair acts upon the rays of light at ſome conſiderable diſtance from it, the action being ſtrongeſt on thoſe rays which are at the leaſt diſtance, and growing weaker and weaker on thoſe which are farther off, as is repreſented in this figure; and from hence it comes to paſs that the ſhadow of the hair is much broader in proportion to the diſtance of the paper from the hair when it is nearer than when it is at a great diſtance.

He found, that it was not material whether the hair was ſurrounded with air, or with any other pellucid ſubſtance; for he wetted a poliſhed plate of glaſs, and laid the hair in the water upon the glaſs, and then laying another poliſhed plate of glaſs upon it, ſo that the water might fill up the ſpace between the glaſſes, and holding them in the beam of light, he found the ſhadow at the ſame diſtances was as big as before. Alſo the ſhadows of ſcratches made in poliſhed plates of glaſs, and the veins in the glaſs, caſt the like broad ſhadows: ſo that this breadth of ſhadow muſt proceed from ſome other cauſe than the refraction of the air.

The ſhadows of all bodies, metals, ſtones, glaſs, wood, horn, ice, &c. in this light were bordered with three parallel fringes, or bands of coloured light, of which that which was contiguous to the ſhadow was the broadeſt and moſt luminous, while that which was the moſt remote was the narroweſt, and ſo faint as not eaſily to be viſible. It was difficult to diſtinguiſh theſe colours, unleſs when the light fell very obliquely upon a ſmooth paper, or ſome other ſmooth white body, ſo as to make them appear much broader than they would otherwiſe have done; but in theſe circumſtances the colours were plainly viſible, and in the following order. The firſt or innermoſt fringe was violet, and deep blue next the ſhadow, light blue, green, and yellow in the middle, and red without. The ſecond fringe was almoſt contiguous to the firſt, and the third to the ſecond; and both were blue within, and yellow and red without; but their colours were very faint, eſpecially thoſe of the third. The colours, therefore, proceeded in the following order from the ſhadow; violet, indigo, pale blue, green, yellow, red; blue, yellow, red; pale blue, pale yellow, and red. The ſhadows, made by ſcratches and bubbles in poliſhed plates of glaſs were bordered with the like fringes of coloured light.

He alſo obſerves, that by looking on the ſun through a feather, or black ribbon, held cloſe to the eye, ſeveral rainbows will appear, the ſhadows which the fibres or threads caſt on the retina being bordered with the like fringes of colours.

Meaſuring theſe fringes and their intervals with the greateſt accuracy, he found the former to be in the progreſſion of the numbers 1, $\surd\frac{1}{3}$, $\surd\frac{1}{5}$, and their intervals to be in the ſame progreſſion with them, that is, the fringes and their intervals together to be in continual progreſſion of the numbers 1, $\surd\frac{1}{2}$, $\surd\frac{1}{3}$, $\surd\frac{1}{4}$, $\surd\frac{1}{5}$, or thereabouts. And theſe proportions held the ſame very nearly at all diſtances from the hair, the dark intervals of the fringes being as broad in proportion to the breadth of the fringes at their firſt appearance as afterwards, at great diſtances from the hair, though not ſo dark and diſtinct.

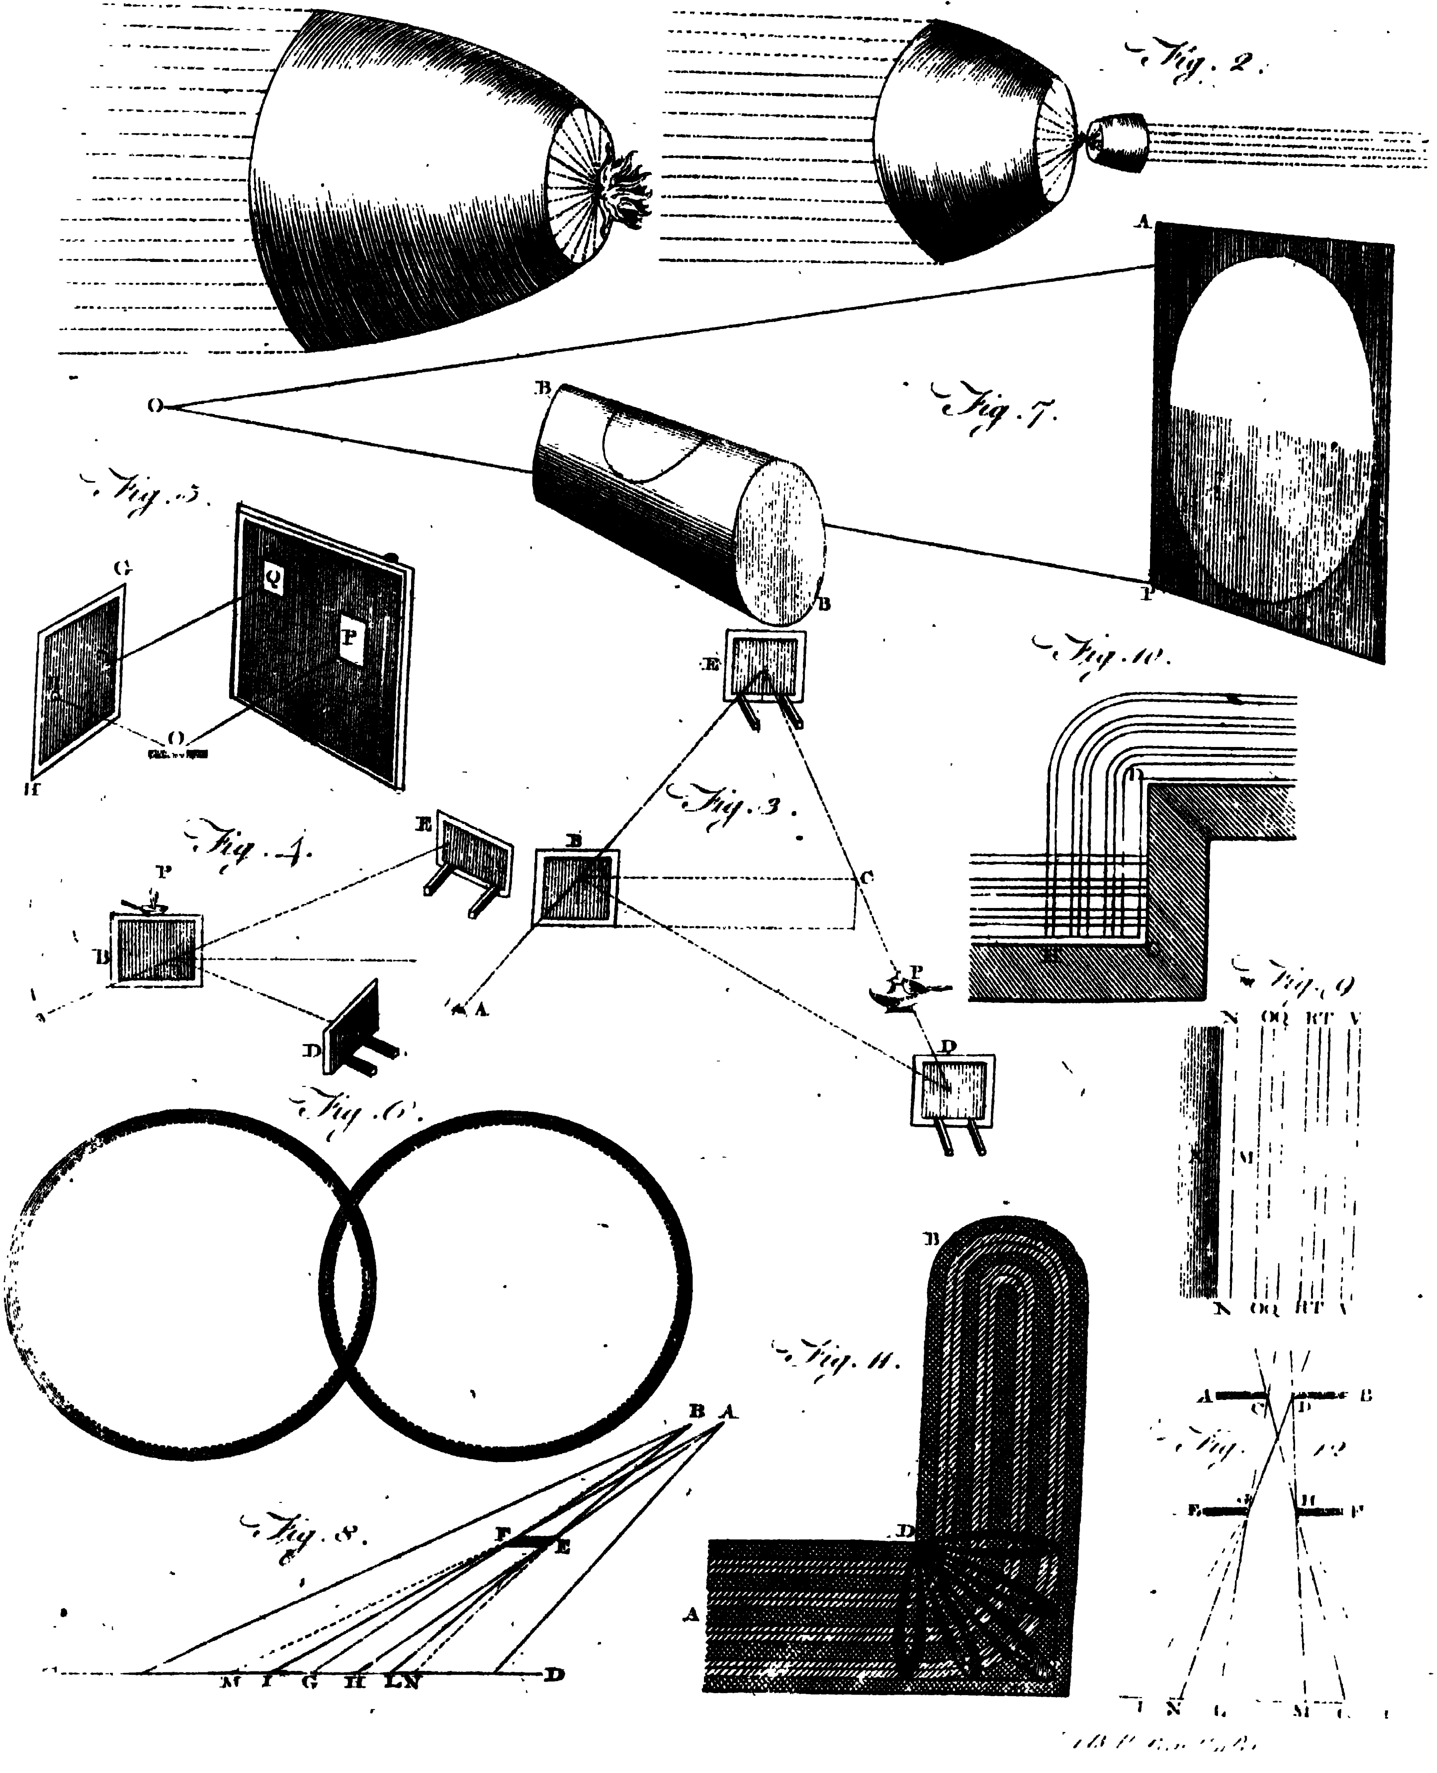
In the next obſervation of our author, we find a very remarkable and curious appearance, which we ſhould hardly have expected from the circumſtances, though it is pretty ſimilar to one that was noticed by Dr Hooke. The ſun ſhining into his darkened chamber, through a hole ¾ of an inch broad, he placed, at the diſtance of two or three feet from the hole, a ſheet of paſteboard, black on both ſides; and in the middle of it he had made a hole about ¼ of an inch ſquare, for the light to paſs through; and behind the hole he faſtened to the paſteboard the blade of a ſharp knife, to intercept ſome part of the light which paſſed through the hole. The planes of the paſteboard and blade of the knife were parallel to one another, and perpendicular to the rays; and when they were ſo placed that none of the light fell on the paſteboard, but all of it paſſed through the hole to the knife, and there part of it fell upon the blade of the knife, and part of it paſſed by its edge, he let that part of the light which paſſed by fall on a white paper, 2 or 3 feet beyond the knife, and there ſaw two ſtreams of faint light ſhoot out both ways from the beam of light into the ſhadow, like the tails of comets. But becauſe the ſun's direct light, by its brightneſs upon the paper, obſcured theſe faint ſtreams, ſo that he could ſcarce ſee them, he made a little hole in the midſt of the paper for that light to paſs through and fall on a black cloth behind it; and then he ſaw the two ſtreams plainly. They were like one another, and pretty nearly equal in length, breadth, and quantity of light. Their light, at that end which was next to the ſun's direct light, was pretty ſtrong for the ſpace of about ¼ of an inch, or ½ of an inch, and decreaſed gradually till it became inſenſible.

The whole length of either of theſe ſtreams, meaſured upon the paper, at the diſtance of 3 feet from the knife, was about 6 or 8 inches; ſo that it ſubtended an angle, at the edge of the knife, of about 10 or 12, or at moſt 14, degrees. Yet ſometimes he thought he ſaw it ſhoot 3 or 4 degrees farther; but with a light ſo very faint, that he could hardly perceive it. This light he ſuſpected might, in part at leaſt, ariſe from ſome other cauſe than the two ſtreams. For, placing his eye in that light, beyond the end of that ſtream which was behind the knife, and looking towards the knife, he could ſee a line of light upon its edge; and that not only when his eye was in the line of the ſtreams, but alſo when it was out of that line, either towards the point of the knife, or towards the handle. This line of light appeared contiguous to the edge of the knife, and was narrower than the light of the innermoſt fringe, and narroweſt when his eye was fartheſt from the direct light; and therefore ſeemed to paſs between the light of that fringe and the edge of the knife; and that which paſſed neareſt the edge ſeemed to be moſt bent, though not all of it.

He then placed another knife by the former, ſo that their edges might be parallel, and look towards one another, and that the beam of light might fall upon both the knives, and ſome part of it paſs between their edges. In this ſituation he obſerved, that when the diſtance of their edges was about the 400th part of an inch, the ſtream divided in the middle, and left a ſhadow between the two parts. This ſhadow was ſo black and dark, that all the light which paſſed between the knives ſeemed to be bent and turned aſide to the one hand or the other; and as the knives ſtill approached one another, the ſhadow grew broader and the ſtreams ſhorter next to it, till, upon the contact of the knives, all the light vaniſhed.

From this experiment our author concludes, that the light which is leaſt bent, and which goes to the inward ends of the ſtreams, paſſes by the edges of the knives at the greateſt diſtance; and this diſtance, when the ſhadow began to appear between the ſtreams, was about the 800th part of an inch; and the light which paſſed by the edges of the knives at diſtances ſtill leſs

OPTICS. **Plate CCCLII.**



and leſs, was more and more faint, and went to thoſe parts of the ſtreams which were farther from the direct light; becauſe, when the knives approached one another till they touched, thoſe parts of the ſtreams vaniſhed laſt which were fartheſt from the direct light.

In the experiment of one knife only, the coloured fringes did not appear; but, on account of the breadth of the hole in the window, became ſo broad as to run into one another, and, by joining, to make one continual light in the beginning of the ſtreams; but in the laſt experiment, as the knives approached one another, a little before the ſhadow appeared between the two ſtreams, the fringes began to appear on the inner ends of the ſtreams, on either ſide of the direct light; three on one ſide, made by the edge of one knife, and three on the other ſide, made by the edge of the other knife. They were the moſt diſtinct when the knives were placed at the greateſt diſtance from the hole in the window, and became ſtill more diſtinct by making the hole leſs; ſo that he could ſometimes ſee a faint trace of a fourth fringe beyond the three above mentioned: and as the knives approached one another the fringes grew more diſtinct and larger, till they vaniſhed; the outermoſt vaniſhing firſt, and the innermoſt laſt. After they were all vaniſhed, and the line of light which was in the middle between them was grown very broad, extending itſelf on both ſides into the ſtreams of light deſcribed before, the above-mentioned ſhadow began to appear in the middle of this line, and to divide it along the middle into two lines of light, and increaſed till all the light vaniſhed. This enlargement of the fringes was ſo great, that the rays which went to the innermoſt fringe ſeemed to be bent about 20 times more when the fringe was ready to vaniſh, than when one of the knives was taken away.

From both theſe experiments compared together, our author concluded, that the light of the firſt fringe paſſed by the edge of the knife at a diſtance greater than the 800th part of an inch; that the light of the ſecond fringe paſſed by the edge of the knife at a greater diſtance than the light of the firſt fringe, and that of the third at a greater diſtance than that of the ſecond; and that the light of which the ſtreams above mentioned conſiſted, paſſed by the edges of the knives at leſs diſtances than that of any of the fringes.

He then got the edges of two knives ground truly ſtraight, and pricking their points into a board, ſo that their edges might look towards one another, and meeting near their points, contain a rectilinear angle, he faſtened their handles together, to make the angle invariable. The diſtance of the edges of the knives from one another, at the diſtance of four inches from the angular point, where the edges of the knives met, was the 8th part of an inch; ſo that the angle contained by their edges was about 1° 54′. The knives being thus fixed together, he placed them in a beam of the ſun's light let into his darkened chamber, through a hole the 42d part of an inch wide, at the diſtance of 10 or 13 feet from the hole; and he let the light which paſſed between their edges fall very obliquely on a ſmooth white ruler, at the diſtance of ½ inch, or an inch, from the knives; and there he ſaw the fringes made by the two edges of the knives run along the edges of the ſhadows of the knives, in lines parallel to thoſe edges, without growing ſenſibly broader, till they met in angles equal to the angle contained by the edges of the knives; and where they met and joined, they ended, without croſſing one another. But if the ruler was held at a much greater diſtance from the knives, the fringes, where they were farther from the place of their meeting, were a little narrower, and they became ſomething broader as they approached nearer to one another, and after they met they croſſed one another, and then became much broader than before.

From theſe obſervations he concluded, that the diſtances at which the light compoſing the fringes paſſed by the knives were not increaſed or altered by the approach of the knives, but that the angles in which the rays were there bent were much increaſed by that approach; and that the knife which was neareſt to any ray determined which way the ray ſhould be bent, but that the other knife increaſed the bending.

When the rays fell very obliquely upon the ruler, at the diſtance of a third part of an inch from the knives, the dark line between the firſt and ſecond fringe of the ſhadow of one knife, and the dark line between the firſt and ſecond fringe of the ſhadow of the other knife, met one another, at the diſtance of the fifth part of an inch from the end of the light which paſſed between the knives, where their edges met one another; ſo that the diſtance of the edges of the knives, at the meeting of the dark lines, was the 160th part of an inch; and one half of that light paſſed by the edge of one knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of that knife; while the other half paſſed by the edge of the other knife, at a diſtance not greater than the 320th part of an inch, and, falling upon the paper, made the fringes of the ſhadow of the other knife. But if the paper was held at a diſtance from the knives greater than the third part of an inch, the dark lines above mentioned met at a greater diſtance than the fifth part of an inch from the end of the light which paſſed between the knives, at the meeting of their edges; ſo that the light which fell upon the paper where thoſe dark lines met paſſed between the knives, where their edges were farther diſtant than the 160th part of an inch. For at another time, when the two knives were 8 feet and 5 inches from the little hole in the window, the light which fell upon the paper where the above-mentioned dark lines met paſſed between the knives, where the diſtance between their edges was, as in the following table, at the diſtances from the paper there noted.

Diſtances of the paper from the knives in inches.	Diſtance between the edges of the knives in milleſimal parts of an inch.

From theſe obſervations he concluded, that the light which makes the fringes upon the paper is not the ſame light at all diſtances of the paper from the knives; but that when the paper is held near the knives, the fringes are made by light which paſſes by the edges of the knives at a leſs diſtance, and is more bent than when the paper is held at a greater diſtance from the knives.

Plate CCCLIII. fig. 2.

When the fringes of the ſhadows of the knives fell perpendicularly upon the paper, at a great diſtance from the knives, they were in the form of hyperbolas, their dimenſions being as follow. Let CA, CB, repreſent lines drawn upon the paper, parallel to the edges of the knives; and between which all the light would fall if it ſuffered no inflection. DE is a right line drawn through C, making the angles ACD, BCE, equal to one another, and terminating all the light which falls upon the paper, from the point where the edges of the knives meet. Then *e i s*, *f k t*, and *g l v*, will be three hyperbolical lines, repreſenting the boundaries of the ſhadow of one of the knives, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Alſo *x i p*, *y k q*, and *z l r*, will be three other hyperbolical lines, repreſenting the boundaries of the ſhadow of the other knife, the dark line between the firſt and ſecond fringes of that ſhadow, and the dark line between the ſecond and third fringes of the ſame ſhadow. Theſe three hyperbolas are ſimilar, and equal to the former three, and croſs them in the points *i*, *k*, and *l*; ſo that the ſhadows of the knives are terminated, and diſtinguiſhed from the firſt luminous fringes, by the lines *e i s* and *x i p*, till the meeting and croſſing of the fringes; and then thoſe lines croſs the fringes in the form of dark lines terminating the firſt luminous fringes on the inſide, and diſtinguiſhing them from another light, which begins to appear at *i*, and illuminates all the triangular ſpace *i p* DE*s*, comprehended by theſe dark lines and the right line DE. Of theſe hyperbolas one aſymptote is the line DE, and the other aſymptotes are parallel to the lines CA and CB.

The ſun ſhining into his darkened room through the ſmall hole mentioned above, he placed at the hole a priſm to refract the light, and to form on the oppoſite wall the coloured image of the ſun; and he found that the ſhadows of all bodies held in the coloured light between the priſm and the wall, were bordered with fringes of the colour of that light in which they were held; and comparing the fringes made in the ſeveral coloured lights, he found that thoſe made in the red light were the largeſt, thoſe made in the violet were the leaſt, and thoſe made in the green were of a middle bigneſs. For the fringes with which the ſhadow of a man's hair were bordered, being meaſured croſs the ſhadow, at the diſtance of ſix inches from the hair, the diſtance between the middle and moſt luminous part of the firſt or innermoſt fringe on one ſide of the ſhadow, and that of the like fringe on the other ſide of the ſhadow, was, in the full red light $\frac{1}{37\frac{1}{4}}$ of an inch, and in the full violet $\frac{1}{37}$. The like diſtance between the middle and moſt luminous parts of the ſecond fringes, on either ſide of the ſhadow, was in the full red light $\frac{1}{22}$ and the violet $\frac{1}{27}$ of an inch; and theſe diſtances of the fringes held the ſame proportion at all diſtances from the hair, without any ſenſible variation.

From theſe obſervations it was evident, that the rays which made the fringes in the red light, paſſed by the hair at a greater diſtance than thoſe which made the like fringes in the violet; ſo that the hair, in cauſing theſe fringes, acted alike upon the red light or leaſt refrangible rays at a greater diſtance, and upon the violet or moſt refrangible rays at a leſs diſtance; and thereby occaſioned fringes of different ſizes, without any change in the colour of any ſort of light.

It may therefore be concluded, that when the hair in the firſt obſervation was held in the white beam of the ſun's light, and caſt a ſhadow which was bordered with three fringes of coloured light, thoſe colours aroſe not from any new modifications impreſſed upon the rays of light by the hair, but only from the various inflections whereby the ſeveral ſorts of rays were ſeparated from one another, which before ſeparation, by the mixture of all their colours, compoſed the white beam of the ſun's light; but, when ſeparated, compoſed lights of the ſeveral colours which they are originally diſpoſed to exhibit.

53 Miraldi's diſcoveries.

The perſon whoſe name we find firſt upon the liſt of thoſe who purſued any experiments ſimilar to thoſe of Newton on inflected light is M. Miraldi; whoſe obſervations chiefly reſpect the inflection of light towards other bodies, whereby their ſhadows are partially illuminated; and many of the circumſtances which he noticed relating to it are well worthy of our attention, as the reader will be convinced from the following account of them.

54 Experiments concerning the ſhadows of cylinders.

He expoſed in the light of the ſun a cylinder of wood three feet long, and 6½ lines in diameter; when its ſhadow, being received upon a paper held cloſe to it, was everywhere equally black and well defined, and continued to be ſo to the diſtance of 23 inches from it. At a greater diſtance the ſhadow appeared to be of two different denſities; for the two extremities of the ſhadow, in the direction of the length of the cylinder, were terminated by two dark ſtrokes, a little more than a line in breadth. Within theſe dark lines there was a faint light, equally diſperſed through the ſhadow, which formed an uniform penumbra, much lighter than the dark ſtrokes at the extremity, or than the ſhadow received near the cylinder. This appearance is repreſented in Plate CCCLIII. fig. 3.

As the cylinder was removed to a greater diſtance from the paper, the two black lines continued to be nearly of the ſame breadth, and the ſame degree of obſcurity; but the penumbra in the middle grew lighter, and its breadth diminiſhed, ſo that the two dark lines at the extremity of the ſhadow approached one another, till at the diſtance of 60 inches, they coincided, and the penumbra in the middle entirely vaniſhed. At a ſtill greater diſtance a faint penumbra was viſible; but it was ill defined, and grew broader as the cylinder was removed farther off, but was ſenſible at a very great diſtance.

Beſides the black and dark ſhadow which the cylinder formed near the opaque body, a narrow and faint penumbra was ſeen on the outſide of the dark ſhadow. And on the outſide of this there was a tract more ſtrongly illuminated than the reſt of the paper.

The breadth of the external penumbra increaſed with the diſtance of the ſhadow from the cylinder, and the breadth of the tract of light on the outſide of it was alſo enlarged; but its ſplendour diminiſhed with the diſtance.

He repeated theſe experiments with three other cylinders of different dimenſions: and from them all he inferred, that every opaque cylindrical body, expoſed to the light of the ſun, makes a ſhadow which is black and dark to the diſtance of 38 to 45 diameters of the cylinder which forms it; and that, at a greater diſtance, the middle part begins to be illuminated in the manner deſcribed above.

In explaining theſe appearances, our author ſuppoſes that the light which diluted the middle part of the ſhadow was occaſioned by the infl[illegible] of the [illegible], which, bending inwards on their near approach to the body, did at a certain diſtance enlighten all the ſhadow, except the edges, which were left undiſturbed. At the ſame time other rays were deflected from the body, and formed a ſtrong light on the outſide of the ſhadow, and which might at the ſame time contribute to dilute the outer ſhadow, though he ſuppoſed that penumbra to be occaſioned principally by that part of the paper not being enlightened, except by a part of the ſun's diſk only, according to the known principles of optics.

55
Concerning thoſe of globes.

The ſame experiments he made with globes of ſeveral diameters; but he found, that, whereas the ſhadows of the cylinders did not diſappear but at the diſtance of 41 of their diameters, thoſe of the globes were not viſible beyond 15 of their diameters; which he thought was owing to the light being inflected on every ſide of a globe, and conſequently in ſuch a quantity as to diſperſe the ſhadows ſooner than in the caſe of the cylinders.

In all theſe caſes, the penumbra occaſioned by the inflected light began to be viſible at a leſs diſtance from the body in the ſtronger light of the ſun than in a weaker, on account of the greater quantity of rays inflected in thoſe circumſtances.

56
His miſtake concerning the moon.

Conſidering the analogy between theſe experiments and the phenomena of an eclipſe of the moon, immerſed in the ſhadow of the earth, he imagined, that part of the light by which ſhe is then viſible is inflected light, and not that which is refracted by the atmoſphere; though this may be ſo copious as to efface ſeveral of the above mentioned appearances, occaſioned by inflected light only. But this gentleman ſhould have conſidered, that as no light is inflected but what paſſes exceedingly near to any body, perhaps ſo near as the diſtance of $\frac{1}{40}$ part of an inch, this cauſe muſt be altogether inadequate to the effect.

Being ſenſible that the above-mentioned phenomena of the ſhadows were cauſed by inflected light, he was induced to give more particular attention to this remarkable property; and, in order to it, to repeat the experiments of Grimaldi and Sir Iſaac Newton in a darkened room. In doing this, he preſently obſerved that, beſides the enlarged ſhadow of a hair, a fine needle, &c. the bright gleam of light that bordered it, and the three coloured rings next to this enlightened part, when the ſhadow was at a conſiderable diſtance from the hair, the dark central ſhadow was divided in the middle by a mixture of light; and that it was not of the ſame denſity, except when it was very near the hair.

This new appearance will be ſeen to be exactly ſimilar to what our philoſopher had obſerved with reſpect to the ſhadows in the open day-light above mentioned; but the following obſervations, which he made with ſome variation of his apparatus, are much more curious and ſtriking, though they ariſe from the ſame cauſe.

Having placed a briſtle, which is thicker than a common hair, in the rays of the ſun, admitted into a dark chamber by a ſmall hole, at the diſtance of nine feet from the hole, it made a ſhadow, which, being received at five or ſix feet from the object, he obſerved to conſiſt of ſeveral ſtreaks of light and ſhade. The middle part was a faint ſhadow, or rather a kind of penumbra, bordered by a darker ſhadow, and after that by a narrower penumbra; next to which was a light ſtreak broader than the dark part, and next to the ſtreak of light, the red, violet, and blue colours were ſeen as in the ſhadow of the hair.

In the ſame manner he placed, in the ſame rays of the ſun, ſeveral needles of different ſizes; but the appearances were ſo exceedingly various, though ſufficiently ſingular, that he does not recite them particularly, but chooſes rather to give, at ſome length, the obſervations he made on the ſhadows of two plates, as by that means he could better explain the phenomena of the round bodies.

57
Experiments concerning the ſhadows of [illegible]

He expoſed in the rays of the ſun, admitted by a ſmall hole into a dark chamber, a plate that was two inches long, and a little more than half a line broad. This plate being fixed perpendicularly to the rays, at the diſtance of nine feet from the hole, a faint light was ſeen uniformly diſperſed over the ſhadow, when it was received perpendicularly to it, and very near. The ſhadow of the ſame plate being received at the diſtance of two feet and a half, was divided into four very narrow black ſtreaks, ſeparated by ſmall lighter intervals equal to them. The boundaries of this ſhadow on each ſide had a penumbra, which was terminated by a very ſtrong light, next to which were the coloured ſtreaks of red, violet, and blue, as before. This is repreſented in Plate CCLIII. fig. 4.

The ſhadow of the ſame plate, at $4\frac{1}{2}$ feet diſtance from it, was divided into two black ſtreaks only, the two outermoſt having diſappeared, as in fig. 5.; but theſe two black ſtreaks which remained were broader than before, and ſeparated by a lighter ſhade, twice as broad as one of the former black ſtreaks, when the ſhadow was taken at $2\frac{1}{2}$ feet. This penumbra in the middle had a tinge of red. After the two black ſtreaks there appeared a pretty ſtrong penumbra, terminated by the two ſtreaks of light, which were now broad and ſplendid, after which followed the coloured ſtreaks.

A ſecond plate, two inches long and a line broad, being placed like the former, 14 feet from the hole by which the rays of the ſun were admitted, its ſhadow being received perpendicularly very near the plate, was illuminated by a faint light, equally diſperſed, as in the caſe of the preceding plate. But being received at the diſtance of 13 feet from the plate, ſix ſmall black

Plate CCCLIII.

ſtreaks began to be viſible, as in fig. 6. At 17 feet from the plate, the black ſtreaks were broader, more diſtinct, and more ſeparated from the ſtreaks that were leſs dark. At 42 feet from the plate, only two black ſtreaks were ſeen in the middle of the penumbra, as in fig. 7. This middle penumbra between the two black ſtreaks was tinged with red. Next to the black ſtreaks there always appeared the ſtreaks of light, which were broad, and the coloured ſtreaks next to them.

Receiving the ſhadow of the ſame plate at the diſtance of 72 feet, the appearances were the ſame as in the former ſituation, except that the two black ſtreaks were broader, and the interval between them, occupied by the penumbra, was broader alſo, and tinged with a deeper red.

In the ſame rays of the ſun he placed different plates, and larger than the former, one of them a line and a half, another two lines, another three lines broad, &c. but receiving their ſhadows upon paper, he could not perceive in them thoſe ſtreaks of faint light which he had obſerved in the ſhadows of the ſmall plates, though he received theſe ſhadows at the diſtance of 56 feet. Nothing was ſeen but a weak light, equally diffuſed, as in the ſhadows of the two ſmalleſt plates, received very near them. But had his dark chamber been large enough, he did not doubt, but that, at a proper diſtance, there would have been the ſame appearances in the ſhadows of the larger plates as in thoſe of the ſmalleſt. For the ſame reaſon, he ſuppoſed, that, if the ſhadows of the ſmall needles could have been diſtinctly viewed very near thoſe bodies, the different ſtreaks of light and ſhade would have been as viſible in them as in thoſe of the ſmall plates; and indeed he did obſerve the ſame appearances in the ſhadows of needles of a middling ſize.

The ſtreaks of light in theſe ſhadows our author aſcribed to the rays of light which are inflected at different diſtances from the bodies; and he imagined that their croſſing one another was ſufficient to account for the variations obſervable in them at different diſtances.

The extraordinary ſize of the ſhadows of theſe ſmall ſubſtances M. Miraldi thought to be occaſioned by the ſhadow from the enlightened part of the ſky, added to that which was made by the light of the ſun, and alſo to a vortex occaſioned by the circulation of the inflected light behind the object; but our readers will probably not think it neceſſary for us either to produce all his reaſons for this hypotheſis, or to enter into a refutation of them.

Our author having made the preceding experiments upon ſingle long ſubſtances, had the curioſity to place two of them ſo as to croſs one another in a beam of the ſun's light. The ſhadows of two hairs placed in this manner, and received at ſome diſtance from them, appeared to be painted reciprocally one upon the other, ſo that the obſcure part of one of them was viſible upon the obſcure part of the other. The ſtreaks of light alſo croſſed one another, and the coloured ſtreaks did the ſame.

Having placed a needle and a hair croſſing one another, their ſhadows, at the ſame diſtance, exhibited the ſame appearances as the ſhadows of the two hairs, though the ſhadow of the needle was the ſtronger.

He alſo placed in the rays of the ſun a briſtle and a plate of iron a line thick, ſo that they croſſed one another obliquely; and when their ſhadows were received at the ſame diſtance, the light and dark ſtreaks of the ſhadow of the briſtle were viſible ſo far as the middle of the ſhadow of the plate on the ſide of the acute angle, but not on the ſide of the obtuſe angle, whether the briſtle or the plate were placed next to the rays. The plate made a ſhadow ſufficiently dark, divided into ſix black ſtreaks; and theſe were again divided by as many light ones equal to them; and yet all the ſtreaks belonging to the ſhadow of the briſtle were viſible upon it, as in fig. 8. To explain this appearance, he ſuppoſed that the rays of the ſun glided a little along the briſtle, ſo as to enlighten part of that which was behind the plate. But this ſeems to be an arbitrary and improbable ſuppoſition.

Our philoſopher did not fail to expoſe ſeveral ſmall globes in the light of the ſun in his dark chamber, and to compare their ſhadows with thoſe of the long ſubſtances, as he had done in the day light, and the appearances were ſtill ſimilar. It was particularly evident, that there was much more light in the ſhadows of the globes than in thoſe of the cylinders, not only when they were both of an equal diameter, but when that of the globe was larger than that of the cylinder, and the ſhadows of both the bodies were received at the ſame diſtance. He alſo obſerved, that he could perceive no difference of light in the ſhadows of the plates which were a little more than one line broad, though they were received at the diſtance of 72 feet; but he could eaſily ſee a difference of ſhades in thoſe of the globes, taken at the ſame diſtance, though they were $2\frac{1}{2}$ lines in diameter.

In order to explain the colours at the edges of theſe ſhadows, he contrived to throw ſome of the ſhadows upon others; and the following obſervations, though they did not enable him to accompliſh what he intended, are curious and worth reciting.

58
Experiments with a mixture of coloured ſhadows.

Having thrown ſeveral of the ſimilar colours upon one another, and thereby produced a tinge more lively than before, he threw the gleam of light, which always intervened between the colours and the darker part of the ſhadow, upon different parts of other ſhadows; and obſerved, that, when it fell upon the exterior penumbra made by another needle, it produced a beautiful ſky blue colour, almoſt like that which was produced by two blue colours thrown together. When the ſame gleam of light fell upon the deeper ſhadow in the middle, it produced a red colour; which ſeemed to prove, that the reddiſh colour in the middle of ſeveral of the ſhadows might come from the little light inflected into that place. But here our author ſeems to have been miſled by ſome falſe hypotheſis concerning colours.

He placed two plates of iron, each three or four lines broad, very near one another, but with a very ſmall interval between them: and having placed them in the rays of the ſun, and received their ſhadows at the diſtance of 15 or 20 feet from them, he ſaw no light between them but a continued ſhadow, in the middle of which were ſome ſtreaks of a lively purple, parallel to one another, and ſeparated by other black ſtreaks; but between them there were other ſtreaks, both of a very faint green, and alſo of a pale yellow.—He alſo informs us, that M. Deliſle had obſerved colours in the ſtreaks of light and ſhade, which are obſervable in ſhadows taken near the bodies.

59
M. Mairan's obſervations.

Among thoſe who followed Sir Iſaac Newton in his obſervations on the inflection of light, we alſo find the ingenious M. Mairan: but, without attempting the diſcovery of new facts, he only endeavoured to explain the old ones, by the hypotheſis of an atmoſphere ſurrounding all bodies; and conſequently making two reflections and refractions of the light that impinges upon them, one at the ſurface of the atmoſphere, and the other at that of the body itſelf. This atmoſphere he ſuppoſed to be of a variable denſity and refractive power, like the air.

60
Diſcoveries of M. Du Tour.

M. Mairan was ſucceeded by M. Du Tour, who thought the variable atmoſphere ſuperfluous, and imagined that he could account for all the phenomena by the help of an atmoſphere of an uniform denſity, and of a leſs refractive power than the air ſurrounding all bodies. But what we are moſt obliged to this gentleman for, is, not his ingenious *hypotheſis*, but the beautiful variety with which he has exhibited the *experiments*, which will render it much eaſier for any perſon to inveſtigate the true cauſes of them.

Before M. Du Tour gave his attention to this ſubject, only three fringes had been obſerved in the colours produced by the inflection of light; but he was accidentally led to obſerve a greater number of them, and adopted from Grimaldi the following ingenious method of making them all appear very diſtinct.

Plate CCCLIII.

He took a circular board ABED (fig. 9.), 13 inches in diameter, the ſurface of which was black, except at the edge, where there was a ring of white paper about three lines broad, in order to trace the circumference of a circle, divided into 360 degrees, beginning at the point A, and reckoning 180 degrees on each hand to the point E; B and D being each of them placed at 90 degrees. A ſlip of parchment three inches broad, and diſpoſed in the form of a hoop, was faſtened round the board, and pierced at the point E with a ſquare hole, each ſide being four or five lines, in order to introduce a ray of the ſun's light. Laſtly, In the centre of the board C, and perpendicular to it, he fixed a pin about $\frac{1}{4}$ of a line in diameter.

This hoop being ſo diſpoſed, that a ray of light entering the dark chamber, through a vertical cleft of two lines and a half in length, and about as wide as the diameter of the pin, went through the hole at E, and paſſing parallel to the plane of the board, projected the image of the ſun and the ſhadow of the pin at A. In theſe circumſtances he obſerved,

1. That quite round the concave ſurface of this hoop, there were a multitude of coloured ſtreaks; but that the ſpace *m*A*n*, of about 18 degrees, the middle of which was occupied by the image of the ſun, was covered with a faint light only.

2. The order of the colours in theſe ſtreaks was generally ſuch that the moſt refrangible rays were the neareſt to the incident ray ECA; ſo that, beginning from the point A, the violet was the firſt and the red the laſt colour in each of the ſtreaks. In ſome of them, however, the colours were diſpoſed in a contrary order.

3. The image of the ſun, projected on each ſide of the point A, was divided by the ſhadow of the pin, which was bordered by two luminous ſtreaks.

4. The coloured ſtreaks were narrower in ſome parts of the hoop than others, and generally decreaſed in breadth in receding from the point A.

5. Among theſe coloured ſtreaks, there were ſometimes others which were white, a line or a line and a half in breadth, which were always bordered on both ſides by a ſtreak of orange colour, at leaſt when the light of the ſun was intenſe, and the chamber ſufficiently dark.

From this experiment he thought it was evident, that the rays which paſſed beyond the pin were not the only ones that were decompoſed, for that thoſe which were reflected back from the pin were decompoſed alſo; from which he concluded that they muſt have undergone ſome refraction. He alſo thought that thoſe which went beyond the pin ſuffered a reflection, ſo that they were all affected in a ſimilar manner.

In order to account for theſe facts our author deſcribes the progreſs of a ray of light through an uniform atmoſphere, which he ſuppoſes to ſurround the pin; and ſhows, that the differently refrangible rays will be ſeparated at their emergence from it: but he refers to ſome experiments and obſervations in a future memoir, to demonſtrate that all the coloured ſtreaks are produced by rays that are both reflected and refracted.

61
Account of Du Tour's hypotheſis.

To give ſome idea of his hypotheſis, he ſhows that the ray *a b*, fig. 10. after being refracted at *b*, reflected at *r* and *u*, and again refracted at *s* and *t*, will be divided into its proper colours; the leaſt refrangible or the red rays iſſuing at *x*, and the moſt refrangible or violet at *y*; which agrees with his obſervations. Thoſe ſtreaks in which the colours appear in a contrary order he thinks are to be aſcribed to inequalities in the ſurface of the pin. This might eaſily have been aſcertained by turning the pin round; in which caſe theſe differently coloured ſtreaks would have changed their places.

If any perſon ſhould chooſe to repeat theſe experiments, he obſerves that it requires that the ſky be very clear and free from vapours, in order to exhibit the colours with the greateſt diſtinctneſs; ſince even the vapours that are imperceptible will diminiſh the luſtre of the colours on every part of the hoop, and even efface ſome of them, eſpecially thoſe which are on that part in which the beam of light enters, as at E, fig. 9. where the colours are always fainter than in any other place, and indeed can never be diſtinguiſhed except when the hole E is confined by black ſubſtances, ſo as to intercept a part of the light that might reach the pin; and unleſs alſo thoſe rays which go beyond the pin to form the image of the ſun at A be ſtopped, ſo that no rays are viſible except thoſe that are reflected towards the hole, and which make the faint ſtreaks.

The coloured ſtreaks that are next the ſhadow of the pin, he ſhows, are formed by thoſe rays which, entering the atmoſphere, do not fall upon the pin; and, without any reflection, are only refracted at their entering

Plate CCCLIII.

entering and leaving the atmoſphere, as at *b* and *r u*, fig. 11. In this caſe, the red or leaſt refrangible rays will iſſue at *r*, and the violet at *u*.

To diſtinguiſh the rays which fell upon the hoop in any particular direction, from thoſe that came in any other, he made an opening in the hoop, as at P, fig. 9. by which means he could, with advantage, and at any diſtance from the centre, obſerve thoſe rays unmixed with any other.

To account for the coloured ſtreaks being larger next the ſhadow of the pin, and growing narrower to the place where the light was admitted, he ſhows, by fig. 12. that the rays *a b* are farther ſeparated by both the refractions than the rays *c d*.

Sometimes our author obſerved, that the broader ſtreaks were not diſpoſed in this regular order; but then he found, that by turning the pin they changed their places, ſo that this circumſtance muſt have been an irregularity depending upon the accidental ſurface of the pin.

The white ſtreaks intermixed with the coloured ones he aſcribes to ſmall cavities in the ſurface of the pin, or ſome other foreign circumſtance; for they alſo changed their places when the pin was made to turn upon its axis.

Other obſervations of our author ſeem to prove that the refracting atmoſpheres ſurrounding all kinds of bodies are of the ſame ſize; for when he placed a great variety of ſubſtances, and of different ſizes alſo, he always found the coloured ſtreaks of the ſame dimenſions.

M. Du Tour obſerves that his hypotheſis contradicts an obſervation of Sir Iſaac Newton, that thoſe rays which paſs the neareſt to any body are the moſt inflected; but he thinks that Newton's obſervations were not ſufficiently accurate. Beſides, he obſerves, that Newton only ſaid that *he thought it to be ſo*, without aſſerting it poſitively.

Since the rays which formed theſe coloured ſtreaks are but little diverted out of their way, our author infers that this atmoſphere is of ſmall extent, and that its refractive power is not much leſs than that of air.

Expoſing two pieces of paper in the beam of light, ſo that part of it paſſed between two planes formed by them, M. Du Tour obſerved, that the edges of this light, received upon paper, were bordered with two orange-coloured ſtreaks, which Newton had not taken notice of in any of his experiments. To account for them, he ſuppoſes, that, in fig. 13. the more refrangible of the rays which enter at *b* are ſo refracted, that they do not reach the ſurface of the body itſelf at R: ſo that the red and orange-coloured light may be reflected from thence in the direction *d*M, where the orange-coloured ſtreaks will be formed; and, for the ſame reaſon, another ſtreak of orange will be formed at *m*, by the rays which enter the atmoſphere on the other ſide of the chink. In a ſimilar manner he accounts for the orange-coloured fringes at the borders of the white ſtreaks, in the experiment of the hoop.

The blue rays, which are not reflected at R, he ſuppoſes, paſs on to I; and that of theſe rays the blue tinge obſervable in the ſhadows of ſome bodies are formed.

62
This hypotheſis uſeleſs and ill-founded.

We may here make a general obſervation, applicable to all the attempts of philoſophers to explain theſe phenomena by atmoſpheres. Theſe attempts give no explanation whatever of what is attempted, *i. e.* the phyſical cauſe of the phenomena. A phenomenon is ſome individual fact or event in nature. We are ſaid to explain it when we point out the *general fact* in which it is comprehended, and ſhow the manner in which it is ſo comprehended, or the particular modification of the general *fact*. Philoſophy reſembles natural hiſtory, having for its ſubject the *events* of nature; and its inveſtigations are nothing but the claſſification of theſe events, or the arrangement of them under the general facts of which they are individual inſtances. In the preſent inſtance there is no general *fact* referred to. The atmoſphere is a mere gratuitous ſuppoſition; and all that is done is to ſhow a reſemblance between the phenomena of inflection of light to what would be the phenomena were bodies ſurrounded with ſuch atmoſpheres; and even in this point of view, the diſcuſſions of Mairan and Du Tour are extremely deficient. They have been ſatisfied with very vague reſemblances to a fact obſerved in *one ſingle inſtance*, and not ſufficiently examined or deſcribed in that inſtance, namely, the refraction of light through the atmoſphere of this globe.

The attempt is to explain how light is turned out of its direction by paſſing near the ſurface of bodies. This indicates the action of forces in a direction tranſverſe to that of the light. Newton took the right road of inveſtigation, by taking the phenomenon in its original ſimplicity, and attending merely to this, that the rays *are* deflected from their former courſe; and the ſole aim of his inveſtigation was to diſcover the laws, *i. e.* the more general facts in this deflection. He deduced from the phenomena, that ſome rays are more deflected than others, and endeavoured to determine in what rays the deflections are moſt remarkable: and no experiment of M. Du Tour has ſhown that he was miſtaken in his modified aſſertion, that thoſe rays are moſt inflected which paſs neareſt to the body. We ſay *modified aſſertion;* for Newton points out with great ſagacity many inſtances of alternate fits of *inflection* and *deflection;* and takes it for granted, that the law of continuity is obſerved in theſe phenomena, and that the chngae of inflection into deflection is gradual.

But theſe analogical diſcuſſions are eminently deficient in another reſpect: They are *(prima facie)* held out as mechanical explanations of the changes of motion obſerved in rays of light. When it ſhall be ſhown, that theſe are preciſely ſuch as are obſerved in refracting atmoſpheres, nothing is done towards deciding the original queſtion; for the action of refracting atmoſpheres preſents it in all its difficulties, and we muſt ſtill aſk *how do theſe atmoſpheres produce this effect?* No advance whatever is gained in ſcience by thruſting in this hypothetical atmoſphere; and Newton did wiſely in attaching himſelf to the ſimple fact: and he thus gives us another ſtep in ſcience, by ſhowing us a fact unknown before, *viz.* that the action of bodies on light is not confined to tranſparent bodies. He then added another general fact to our former ſtock, *that light as well as other matter is acted on at a diſtance;* and thus he made a very important deduction, *that reflection,*

63
Reflection, refraction, and inflection probably produced by the ſame forces.

flection, refraction, and inflection, are probably brought about by the ſame forces.

We would extend this obſervation to all attempts of philoſophers to explain the phenomena of nature by the *immediate* action of inviſible fluids, magnetical, electrical, nervous, ethers, &c. and we would add that, all of them are equally illogical. They are all attempts to explain changes of motion by impulſe; and proceed on the previous ſuppoſition, that the changes of motion by impulſe are perfectly underſtood; a ſuppoſition quite gratuitous, nay falſe. We may challenge any philoſopher to demonſtrate, from unexceptionable principles, and by juſt argument, what will be the effect of one particle of matter in motion meeting with another particle at reſt, theſe two particles conſtituting the whole of the univerſe. The queſtion is to this day undecided.

But this is not all—changes of motion by impulſe are very familiar, and the general laws are pretty well known; ſo that when it can be ſhown that impulſe really operates in a phenomenon, we are ſatisfied with the explanation. When we ſee a glaſs ball hanging as a pendulum put in motion by the ſtroke of another equal ball ſimilarly ſuſpended, we think its motion is ſufficiently explained by the common laws of colliſion. But this is a very incomplete view of the matter. It remains to be proved, that the motion was really produced by impulſe, that is, by the one ball's coming into contact with the other; and we ſhall find that *real* impulſe is far from being ſo familiar as we imagine.

When one object glaſs of a very long teleſcope lies upon another, nothing is obſerved at the place of contact of the two ſpherical glaſſes, unleſs the weight of the upper one be conſiderable; in which caſe a greaſy-like ſpot is obſerved. If now the upper glaſs be preſſed on the other, the ſpot will increaſe in diameter, and have a coloured margin. By gradually increaſing the preſſure, the breadth of the coloured ſpot will increaſe, and it will be found to conſiſt of concentric arches of different colours, increaſing in number and breadth by an increaſe of preſſure. When this is ſufficiently great, a black or unreflecting ſpot appears in the middle, ſharply defined, with a ſilvery margin, and increaſing in breadth with the preſſure. No additional preſſure makes any change excepting in the diameters of the coloured rings. When the preſſure is gradually diminiſhed, the rings contract, the black ſpot vaniſhes, and all the colours vaniſh in the contrary order to that of their firſt appearance. When the preſſure is meaſured, which is neceſſary for producing the black ſpot, it is found conſiderably to exceed 800 pounds for every ſquare inch of the black ſpot.

64
800 pounds weight on every ſquare inch neceſſary to bring two bodies into apparent contact.

It is inconteſtably proved, that the coloured rings are produced by the reflection of light in thoſe parts where the glaſſes are at certain ſmall diſtances from each other, meaſurable by means of the diameters of the coloured rings and the diameter of the ſpheres, of which the adjoining ſurfaces of the glaſſes are portions; and the want of reflection in the middle ſeems to indicate the want of this neceſſary diſtance, and that the two glaſſes are there in contact, making but one, their ſurfaces being flattened by compreſſion. The glaſſes ſeem to be kept aſunder by mutual forces, which are overcome by external preſſure, and which again ſeparate them when the preſſure is removed.

When therefore the glaſs ball mentioned above puts the other in motion by ſtriking it, we are entitled to ſay, that unleſs the preſſure during the ſtroke has been equal to 800 pounds for every ſquare inch of contact, the motion has been produced without contact or real impulſe, by the action of repulſive forces exerted between the balls, in the ſame manner as would happen between two magnets floating on cork with their north poles fronting each other; in which caſe (if the motion has been ſufficiently ſlow) the ſtriking magnet will be brought to reſt, and the other move off, with its original velocity, in the ſame manner as happens to the glaſs balls. Many ſuch communications of motion happen, where we cannot ſay that the impulſive preſſure is greater than that now mentioned; and in ſuch caſes we are well entitled to ſay, that the motion has been produced without real impulſe, by repulſive forces acting at a diſtance. This evidently diminiſhes to a great degree the familiarity of the fact of impulſe.

65
Motion produced without impulſe.

But we conclude too haſtily, from the phenomena of the object glaſſes, that a preſſure exceeding 800 pounds on the ſquare inch will produce contact.

Blow a ſoap bubble, and let it fall on a piece of cloth, and cover it with a glaſs bell: after ſome time you will obſerve rings of colours on its upper part, which will increaſe in number and breadth, and be in every reſpect ſimilar to thoſe between the object glaſſes. Theſe ariſe from the gradual thinning of the upper part of the ſoap bubble; a certain thickneſs of this, as well as of the interval between the glaſſes, invariably reflecting a certain colour. At laſt a black ſpot appears a-top, which is ſharply defined, and increaſes in diameter. Soon after this the bubble burſts. Thus then there is a certain thickneſs neceſſary for enabling the plate of ſoap ſuds to reflect light ſo as to be very ſenſible. Analogy obliges us to extend this to the object glaſſes, and to ſay, not that the glaſſes touch each other through the extent of the black ſpot, but that their diſtance is there too ſmall for the ſenſible reflection of light; and it remains undecided whether any preſſure, however great, can annihilate all diſtance between them. So far, therefore, from impulſe being a familiar fact, and its ſuppoſed laws being proper and logical principles of reaſoning and explanation, it appears extremely doubtful whether the fact has *ever* been obſerved; and it muſt therefore be againſt the rules of logic to adduce the laws of impulſe for the explanation of any abſtruſe phenomenon.

66
It is doubtful whether impulſe has ever been obſerved.

Ether and other fluid atmoſpheres have often been reſorted to by philoſophers puzzled for an explanation; and all this trouble has been taken to avoid the ſuppoſed difficulty of bodies acting at a diſtance. We now ſee that this is only putting the difficulty a ſtep farther off. We may here add, that in all theſe attempts the very thing is ſuppoſed which the philoſophers wiſh to avoid. Theſe ethers have been fitted for their taſks by ſuppoſing them of variable denſities. It is quite eaſy to ſhow, that ſuch a variation in denſity cannot be conceived without ſuppoſing the particles to act on particles not in contact with them, and to a diſtance as great as that to which the change of denſity extends. The very ſimpleſt form of an elaſtic fluid ſuppoſes this, either with reſpect to its own particles, or with reſpect to the particles of a ſtill more ſubtile.

67
Suppoſed ethers furniſh no account of the phenomena of inflection.

ſubtile fluid, from the interſperſion of which it derives its elaſticity. To get rid of one action at a diſtance, therefore, we introduce millions. Inſtead, therefore, of naturaliſts pluming themſelves on ſuch explanations, and having recourſe, in all their difficulties, to the *ether of Sir Iſaac Newton*, which they make a drudge, a *Mungo here, Mungo there, Mungo everywhere*; let us rather wonder how that great man, not more eminent for penetration and invention than for accuracy of conception and juſtneſs of reaſoning, ſhould ſo far forget himſelf, and deviate from that path of logical inveſtigation in which he had moſt ſucceſsfully advanced, and ſhould, in his fabrication of ether, and application of it to explain the more abſtruſe phenomena of nature, at once tranſgreſs *all* the rules of philoſophizing which he had preſcribed to himſelf and others. Let this ſlip, this mark of frail mortality, put us on our guard, leſt we alſo be ſeduced by the ſpecious offers of explanation which are held out to us by means of inviſible atmoſpheres of every kind.

68 Objects ſometimes magnified by the inflection of light.

M. Le Cat has well explained a phenomenon of viſion depending upon the inflection of light, which ſhows, that, in ſome caſes objects appear magnified by this means. Looking at a diſtant ſteeple, when a wire, of a leſs diameter than the pupil of his eye, was held pretty near to it, and drawing it ſeveral times betwixt his eye and that object, he was ſurpriſed to find, that, every time the wire paſſed before his pupil, the ſteeple ſeemed to change its place, and ſome hills beyond the ſteeple ſeemed to have the ſame motion, juſt as if a lens had been drawn betwixt his eye and them.

Examining this appearance more attentively, he found that there was a poſition of the wire, but very difficult to keep, in which the ſteeple ſeemed not to have any motion, when the wire was paſſed before his eye; and in this caſe the ſteeple appeared leſs diſtinctly, and ſeemed to be magnified. Theſe effects being ſimilar to thoſe of a lens, he attended to them more particularly; and placed his eye in ſuch a manner with reſpect to the ſteeple, that the rays of light by which he ſaw it muſt come very cloſe to the edge of a window, where he had placed himſelf to make his obſervations. Then paſſing the wire once more before his eye, he obſerved, that, when it was in the viſual axis, the ſteeple appeared nearer to the window, on whichever ſide the wire was made to approach. He repeated this experiment, and conſtantly with the ſame reſult, the object being always magnified, and nearly doubled, by this means.

Plate CCCLIII.

This phenomenon is eaſily explained by fig. 14. in which B repreſents the eye, A the ſteeple, and C the diameter of the wire. The black lines expreſs the cone of light by which the natural image of the ſteeple A is formed, and which is much narrower than the diameter of the wire C; but the dotted lines include not only that cone of light, ſtopped and turned out of its courſe by the wire, but alſo more diſtant rays inflected by the wire, and thereby thrown more converging into the pupil; juſt as would have been the effect of the interpoſition of a lens between the eye and the object. The reſult of this experiment was the ſame, whatever ſubſtances he made uſe of in the place of the wire, provided they were of the ſame diameter.

§ 5. *Diſcoveries concerning Viſion.*

69 Diſcoveries of Maurolycus, Kepler, &c. concerning viſion.

Maurolycus was the firſt who ſhowed the true theory of viſion, by demonſtrating that the cryſtalline humour of the eye is a lens which collects the light iſſuing from external objects, and throws them upon the retina, where is the focus of each pencil. He did not however find out, that, by means of this refraction of the rays, an image of every viſible object was formed upon the retina, though this ſeems hardly to have been a ſtep beyond the diſcovery he had already made. Montucla indeed conjectures, that he was prevented from mentioning this part of the diſcovery by the difficulty of accounting for the upright appearance of objects, as the image on the retina is always inverted. This diſcovery was made by Kepler; but he, too, was much difficulted with the inverted poſition of the image. The rectification of theſe images, he ſays, is the buſineſs of the mind; which, when it perceives an impreſſion on the lower part of the retina, conſiders it as made by rays proceeding from the higher parts of objects; tracing the rays back to the pupil, where they croſs one another. But this hypotheſis can ſcarcely be deemed ſatisfactory.—Kepler did not pretend to account for the manner in which the mind perceives the images upon the retina, and very much blames Vitellio for attempting prematurely to determine a queſtion of this nature, and which indeed, he ſays, does not belong to optics. He accounts, however, though not in a ſatisfactory manner, for the power we have of ſeeing diſtinctly at different diſtances.

70 Diſcoveries of Scheiner.

The diſcovery concerning viſion was completed by Scheiner. For, in cutting away the coats of the back part of the eyes of ſheep and oxen, and preſenting ſeveral objects before them, within the uſual diſtance of viſion, he ſaw their images diſtinctly and beautifully painted upon the retina. He did the ſame thing with the human eye, and exhibited this curious experiment at Rome in 1625. He takes particular notice of the reſemblance between the eye and the camera obſcura, and explains a variety of methods to make the images of objects erect. As to the images of objects being inverted in the eye, he acquieſces in the reaſon given for it by Kepler. He knew that the pupil of the eye is enlarged in order to view remote objects, and that it is contracted while we are viewing thoſe that are near; and this he proved by experiment, and illuſtrated by figures.

Scheiner alſo took a good deal of pains to aſcertain the denſity and refractive power of all the humours of the eye, by comparing their magnifying power with that of water or glaſs in the ſame form and circumſtances. The reſult of his inquiries was, that the aqueous humour doth not differ much from water in this reſpect, nor the cryſtalline from glaſs; and that the vitreous humour is a medium between both. He alſo very accurately and minutely traces the progreſs of the rays of light through all the humours of the eye; and after diſcuſſing every poſſible hypotheſis concerning the proper ſeat of viſion, he demonſtrates that it is in the retina, and ſhows that this was the opinion of Alhazen, Vitellio, Kepler, and all the moſt eminent philoſophers. He produces many reaſons of his own for this hypotheſis; anſwers a great number of objections to it; and, by a variety of arguments, refutes the opinion of former times, that the ſeat of viſion is in the cryſtalline.

71 Diſcoveries of Deſcartes.

Deſcartes makes a good number of obſervations on the phenomena of viſion. He explains ſatisfactorily the natural methods of judging of the magnitudes, ſituations, and diſtances, of objects, by the direction of the optic axes; comparing it to a blind man's judging of the ſize and diſtance of an object, by feeling at it with two ſticks of a known length, when the hands in which he holds them are at a known diſtance from each other. He alſo obſerves, that having been accuſtomed to judge of the ſituation of objects by their images falling on a particular part of the eye; if by any diſtortion of the eye they fall on a different place, we are apt to miſtake their ſituation, or imagine one object to be two; as till we become accuſtomed to it, we imagine one ſtick to be two, when it is placed between two contiguous fingers laid acroſs one another. But he obſerves, that all the methods we have of judging of the diſtances of objects are very uncertain, and extend but to narrow limits. The direction of the optic axes, he ſays, will not ſerve us beyond 15 or 20 feet, and the change of form of the cryſtalline not more than three or four feet. For he imagined that the eye conforms itſelf to the view of near or diſtant objects by a change in the curvature of the cryſtalline which he ſuppoſed to be a muſcle, the tendons of it being the proceſſus ciliares. In another place, he ſays, that the change in the conformation of the eye is of no uſe to us for the purpoſe of judging of diſtances beyond four or five feet, and the angle of the optic axes not more than 100 or 200 feet; for this reaſon, he ſays, that the ſun and moon are conceived to be much more nearly of the ſame ſize than they are in reality. White and luminous objects, he ſays, appear larger than others, and alſo the parts contiguous to thoſe on which the rays actually impinge; and for the ſame reaſon, if the objects be ſmall, and placed at a great diſtance, they will always appear round, the figure of the angles diſappearing.

72 Berkeley's theory of viſion.

The celebrated Berkeley biſhop of Cloyne, publiſhed, in 1709, *An Eſſay towards a New Theory of Viſion*, which contains the ſolution of many difficulties. He does not admit that it is by means of thoſe lines and angles, which are extremely uſeful in explaining the theory of optics, that different diſtances are judged of by the ſenſe of ſight; neither does he think that the mere direction of the optic axes or the greater or leſs divergency of the rays of light are ſufficient for this purpoſe. "I appeal (ſays he) to any one's experience, whether, upon ſight of an *object*, he compute its diſtance by the bigneſs of the angle made by the meeting of the two *optic axes*? or whether he ever thinks of the greater or leſs divergency of the rays which arrive from any point to his pupil? Nay, whether it be not perfectly impoſſible for him to perceive, by ſenſe, the various angles wherewith the rays according to their greater or leſſer divergency fell upon his eye?" That there is a neceſſary connexion between theſe various angles, &c. and different degrees of diſtance, and that this connexion is known to every perſon ſkilled in optics, he readily acknowledges; but "in vain (ſays he) ſhall all the mathematicians in the world tell me, that I *perceive* certain *lines* and *angles*, which introduce into my mind the various notions of *diſtance*, ſo long as I am myſelf conſcious of no ſuch thing." Diſtance, magnitude, and even figure, he maintains to be the objects of immediate perception only by the ſenſe of touch; and that when we judge of them by ſight, it is from different ſenſations felt in the eye which experience has taught us to be the conſequence of viewing objects of greater or leſs magnitude, of different figures, and at different diſtances. Theſe various ſenſations, with the reſpective diſtances figures, and magnitudes by which they are occaſioned, become ſo cloſely aſſociated in the mind long before the period of diſtinct recollection, that the preſence of the one inſtantly ſuggeſts the other; and we attribute to the ſenſe of ſight thoſe notions which are acquired by the ſenſe of touch, and of which certain *viſual* ſenſations are merely the ſigns or ſymbols, juſt as words are the ſymbols of ideas. Upon theſe principles he accounts, in a manner worthy of the reader's attention, for a ſingle viſion by both eyes, and for our perceiving objects erect by inverted images of them on the retina tunica. Subſequent writers have made great diſcoveries in the theory of viſion; and among them there is hardly any one to whom this branch of ſcience is ſo much indebted as to Dr Reid. Their reaſonings, however, our limits will not permit us to detail, nor do they properly belong to this part of the article; they are connected with the deſcription of the eye itſelf, the various modes of viſion, and optical deceptions to which we are liable; and theſe will be conſidered in a ſucceeding part of this treatiſe.

§ 6. *Of Optical Inſtruments, and diſcoveries concerning them.*

73 Invention of ſpectacles.

So little were the ancients acquainted with the ſcience of optics, that they ſeem to have had no inſtruments of the optical kind, excepting the glaſs globes and ſpeculums formerly mentioned, which they uſed in ſome caſes for magnifying and burning. Alhazen, as we have ſeen, gave the firſt hint of the invention of ſpectacles, and it is probable that they were found out ſoon after his time. From the writings of Alhazen, together with the obſervations and experiments of Roger Bacon, it is not improbable that ſome monks gradually hit upon the conſtruction of ſpectacles; to which Bacon's leſſer ſegment, notwithſtanding his miſtake concerning it, was a nearer approach than Alhazen's larger one. Whoever they were that purſued the diſcoveries of Bacon, they probably obſerved, that a very ſmall convex glaſs, when held at a greater diſtance from the book, would magnify the letters more than when it was placed cloſe to them, in which poſition only Bacon ſeems to have uſed it. In the next place, they might try whether two of theſe ſmall ſegments of a ſphere placed together, or a glaſs convex on both ſides, would not magnify more than one of them. They would then find, that two of theſe glaſſes, one for each eye, would anſwer the purpoſe of reading better than one; and, laſtly, they might find, that different degrees of convexity ſuited different perſons.

It is certain that ſpectacles were well known in the 13th century, and not long before. It is ſaid that

Alexander Spina, a native of Piſa, who died in 1313, and who was very ingenious in executing whatever he ſaw or heard of as having been done by others, happened to ſee a pair of ſpectacles in the hands of a perſon who would not explain them to him; but that he ſucceeded in making a pair for himſelf, and immediately made the conſtruction public for the good of others. It is alſo inſcribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died 1317, that he was the inventor of ſpectacles.

74 Of concave glaſſes.

The uſe of concave glaſſes, to help thoſe perſons who are ſhort-ſighted, was probably a diſcovery that followed not long after that of convex ones, for the relief of thoſe whoſe ſight is defective in the contrary extreme, though we find no trace of this improvement. Whoever made this diſcovery, it was probably the reſult of nothing more than a random experiment. Perhaps a perſon who was ſhort-ſighted, finding that convex glaſſes did him more harm than good, had the curioſity to make trial of a contrary curvature of the glaſs.

75 Deſcartes's account of the invention of teleſcopes.

From this time, though both convex and concave lenſes were ſufficiently common, yet no attempt was made to form a teleſcope by a combination of them, till the end of the 16th century. Deſcartes conſiders James Metius, a perſon who was no mathematician, though his father and brother had applied to thoſe ſciences, as the firſt conſtructor of a teleſcope: and ſays, that as he was amuſing himſelf with making mirrors and burning glaſſes, he caſually thought of looking through two of his lenſes at a time; and that happening to take one that was convex and another that was concave, and happening alſo to hit upon a pretty good adjuſtment of them, he found, that, by looking through them, diſtant objects appeared very large and diſtinct. In fact, without knowing it, he had made a teleſcope.

76 Other accounts.

Other perſons ſay, that this great diſcovery was firſt made by John Lipperſheim, a maker of ſpectacles at Middleburgh, or rather by his children; who, like Metius, were diverting themſelves with looking through two glaſſes at a time, and placing them at different diſtances from one another. But Borellus, the author of a book entitled, *De vero teleſcopii inventore*, gives this honour to Zacharias Joannides, i. e. Janſen, another maker of ſpectacles at the ſame place, who made the firſt teleſcope in 1590; and it ſeems now to be the general opinion, that this account of Borellus is the moſt probable.

77 Borellus's account probably the true one.

Indeed, Borellus's account of the diſcovery of teleſcopes is ſo circumſtantial, and ſo well authenticated, that it does not ſeem poſſible to call it in queſtion. It is not true, he ſays, that this great diſcovery was made by a perſon who was no philoſopher: for Zacharias Janſen was a diligent inquirer into nature; and being engaged in theſe purſuits, he was trying what uſes could be made of lenſes for thoſe purpoſes, when he fortunately hit upon the conſtruction.

This ingenious mechanic, or rather philoſopher, had no ſooner found the arrangement of glaſſes that produced the effect he deſired, than he encloſed them in a tube, and ran with his inſtrument to Prince Maurice; who, immediately conceiving that it might be of uſe to him in his wars, deſired the author to keep it a ſecret. But this, though attempted for ſome time, was found to be impoſſible; and ſeveral perſons in that city immediately applied themſelves to the making and ſelling of teleſcopes. One of the moſt diſtinguiſhed of theſe was Hans Laprey, called *Lipperſheim* by Sirturus. By him ſome perſon in Holland being very early ſupplied with a teleſcope, he paſſed with many for the inventor; but both Metius above mentioned, and Cornelius Drebell of Alcmaar, in Holland, applied to the inventor himſelf in 1620; as alſo did Galileo, and many others. The firſt teleſcope made by Janſen did not exceed 15 or 16 inches in length; but Sirturus, who ſays that he had ſeen it, and made uſe of it, thought it the beſt that he had ever examined.

78 The firſt teleſcope an exceedingly good one.

Janſen, having a philoſophical turn, preſently applied his inſtrument to ſuch purpoſes as he had in view when he hit upon the conſtruction. Directing it towards celeſtial objects, he diſtinctly viewed the ſpots on the ſurface of the moon; and diſcovered many new ſtars, particularly ſeven pretty conſiderable ones in the Great Bear. His ſon Joannes Zacharias, noted the lucid circle near the limb of the moon, from whence ſeveral bright rays ſeem to dart in different directions: and he ſays, that the full moon, viewed through this inſtrument, did not appear flat, but was evidently ſpherical, the middle part being prominent. Jupiter alſo, he ſays, appeared round, and rather ſpherical; and ſometimes he perceived two, ſometimes three, and at the moſt four ſmall ſtars, a little above or below him; and, as far as he could obſerve, they performed revolutions round him; but this, he ſays, he leaves to the conſideration of aſtronomers. This, it is probable, was the firſt obſervation of the ſatellites of Jupiter, though the perſon who made it was not aware of the importance of his diſcovery.

79 Honour of the invention claimed by Fontana.

One Francis Fontana, an Italian, alſo claims the invention; but as he did not pretend to have made it before the year 1608, and as it is well known that the inſtruments were made and ſold in Holland ſome time before, his pretenſions to a ſecond diſcovery are not much regarded.

80 A teleſcope made by Galileo without ſeeing one.

There are ſome who ſay that Galileo was the inventor of teleſcopes; but he himſelf acknowledges, that he firſt heard of the inſtrument from a German; but he ſays, that being informed of nothing more than the effects of it, firſt by common report, and a few days after by a French nobleman, J. Badovere, at Paris, he himſelf diſcovered the conſtruction, by conſidering the nature of refraction: and thus he had much more real merit than the inventor himſelf.

The account of what Galileo actually did in this buſineſs is ſo circumſtantially related by the author of his life, prefixed to the quarto edition of his works, printed at Venice in 1744, and it contains ſo many particulars, which cannot but be pleaſing to every perſon who is intereſted in the hiſtory of teleſcopes, that we ſhall abridge a part of it, intermixing circumſtances collected from other accounts.

81 Account of his diſcoveries.

About April or May, in 1609, it was reported at Venice, where Galileo (who was profeſſor of mathematics in the univerſity of Padua) then happened to be, that a Dutchman had preſented to Count Maurice of Naſſau, a certain optical inſtrument, by means of which, diſtant objects appeared as if they were near; but no farther account of the diſcovery had reached that place, though this was near 20 years after the firſt diſcovery. Struck, however, with this account, Galileo inſtantly returned to Padua, conſidering what kind of an inſtrument this muſt be. The night following, the conſtruction occurred to him; and the day after, putting the parts of the inſtrument together, as he had previouſly conceived of it, and notwithſtanding the imperfection of the glaſſes that he could then procure, the effect anſwered his expectations, as he preſently acquainted his friends at Venice, to which place he ſix days afterwards carried another and a better inſtrument that he had made, and where, from ſeveral eminences, he ſhowed to ſome of the principal ſenators of that republic a variety of diſtant objects, to their very great aſtoniſhment. When he had made farther improvements in the inſtrument, he, with his uſual generoſity and frankneſs in communicating his diſcoveries, made a preſent of one of them to the Doge, Leonardo Donati, and at the ſame time to all the ſenate of Venice; giving along with the inſtrument a written paper, in which he explained the ſtructure and wonderful uſes that might be made of it both by land and at ſea. In return for ſo noble an entertainment, the republic, on the 25th of Auguſt, in the ſame year, more than tripled his ſalary as profeſſor.

Our philoſopher, having amuſed himſelf for ſome time with the view of terreſtrial objects, at length directed his tube towards the heavens; and, obſerving the moon, he found that the ſurface of it was diverſified with hills and valleys, like the earth. He found that the *via lactea* and *nebulæ* conſiſted of a collection of fixed ſtars, which, on account either of their vaſt diſtance, or extreme ſmallneſs, were inviſible to the naked eye. He alſo diſcovered innumerable fixed ſtars diſperſed over the face of the heavens, which had been unknown to all the ancients; and examining Jupiter, with a better inſtrument than any he had made before, he found that he was accompanied by four ſtars, which, in certain fixed periods, performed revolutions round him, and which, in honour of the houſe of Medicis, he called *Medicean planets*.

This diſcovery he made in January 1610, new ſtyle; and continuing his obſervations the whole of February following, in the beginning of March next he publiſhed an account of all his diſcoveries, in his *Nuncius Sidereus*, printed at Venice, and dedicated to Coſmo great duke of Tuſcany, who, by a letter which he wrote to him on the 10th of July 1610, invited him to quit Padua, and aſſigned him an ample ſtipend, as primate and extraordinary profeſſor at Piſa, but without any obligation to read lectures, or to reſide.

The extraordinary diſcoveries contained in the Nuncius Sidereus, which was immediately reprinted both in Germany and France, were the cauſe of much ſpeculation and debate among the philoſophers and aſtronomers of that time; many of whom could not be brought to give any credit to Galileo's account, while others endeavoured to decry his diſcoveries as being nothing more then fictions or illuſions. Some could not be prevailed upon even to look through a teleſcope; ſo devoted were they to the ſyſtem of Ariſtotle, and ſo averſe to admit any other ſource of knowledge beſides his writings. When it was found to be in vain to oppoſe the evidence of ſenſe, ſome did not ſcruple to aſſert that the invention was taken from Ariſtotle; and producing a paſſage from his writings, in which he attempts to give a reaſon why ſtars are ſeen in the day time from the bottom of a deep well, ſaid, that the well correſponded to the tube of the teleſcope, and that the vapours which aroſe from it gave the hint of putting glaſſes into it; and, laſtly, that in both caſes the ſight is ſtrengthened by the tranſmiſſion of the rays through a thick and dark medium. Galileo himſelf tells this ſtory with a great deal of humour; comparing ſuch men to alchymiſts, who imagine that the art of making gold was known to the ancients, but lay concealed under the fables of the poets.

In the beginning of July of the ſame year, 1610, Galileo being ſtill at Padua, and getting an imperfect view of Saturn's ring, imagined that that planet conſiſted of three parts; and therefore, in the account which he gave of this diſcovery to his friends, he calls it *planetam tergeminam*.

Whilſt he was ſtill at Padua, which muſt have been either in the ſame month of July, or the beginning of Auguſt following, he obſerved ſome ſpots on the face of the ſun: but, contrary to his uſual cuſtom, he did not chooſe, at that time, to publiſh his diſcovery; partly for fear of incurring more of the hatred of many obſtinate Peripatetics; and partly in order to make more exact obſervations on this remarkable phenomenon, and to form ſome conjecture concerning the probable cauſe of it. He therefore contented himſelf with communicating his obſervations to ſome of his friends at Padua and Venice, among whom we find the name of Father Paul. This delay, however, was the cauſe of this diſcovery being conteſted with him by the famous Scheiner, who likewiſe made the ſame obſervation in Oct. 1611, and we ſuppoſe had anticipated Galileo in the publication of it.

About the end of Auguſt, Galileo left Padua and went to Florence; and in November following he was ſatisfied, that, from the September preceding, Venus had been continually increaſing in bulk, and that ſhe changed her phaſes like the moon. About the end of March 1611, Galileo went to Rome, where he gratified the cardinals, and all the principal nobility, with a view of the new wonders he had diſcovered in the heavens, and among others the ſolar ſpots.

82
Named
Lynceus
from them.

From theſe diſcoveries Galileo obtained the name of *Lynceus*, after one of the Argonauts, who was famous in antiquity for the acuteneſs of his ſight; and moreover, the marquis of Monticelli inſtituted an academy, with the title of *De Lincei*, and made him a member of it. Twenty-nine years Galileo enjoyed the uſe of his teleſcope, continually enriching aſtronomy with his obſervations: but by too cloſe an application to that inſtrument, and the detriment he received from the nocturnal air, his eyes grew gradually weaker, till in 1639 he became totally blind; a calamity which, however, neither broke his ſpirits, nor interrupted the courſe of his ſtudies.

83
Account
of his teleſcopes.

The firſt teleſcope that Galileo conſtructed magnified only three times; but preſently after, he made another which magnified 18 times; and afterwards, with great trouble and expence, he conſtructed one that magnified 33 times; and with this it was that he diſcovered the ſatellites of Jupiter and the ſpots of the ſun.

84
The rationale of the inſtrument firſt diſcovered by Kepler.

Notwithſtanding Galileo muſt be allowed to have conſiderable merit with reſpect to teleſcopes, it was neither that of the perſon who firſt hit upon the conſtruction, nor that of him who thoroughly explained the *rationale* of the inſtrument. This important ſervice to ſcience was performed by John Kepler, whoſe name is famous on many accounts in the annals of philoſophy, and eſpecially by his diſcovery of the great law of motion reſpecting the heavenly bodies; which is, that the ſquares of their periodical times are as the cubes of their diſtances from the body about which they revolve; a propoſition which, however, was not demonſtrated before Sir Iſaac Newton. Kepler was aſtronomer to ſeveral of the emperors of Germany; he was the aſſociate of the celebrated aſtronomer Tycho Brahe, and the maſter of Deſcartes.

Kepler made ſeveral diſcoveries relating to the nature of viſion; and not only explained the *rationale* of the teleſcope which he found in uſe, but alſo pointed out methods of conſtructing others of ſuperior powers and more commodious application.

It was Kepler who firſt gave a clear explication of the effects of lenſes, in making the rays of a pencil of light converge or diverge. He ſhowed, that a plano-convex lens makes rays that were parallel to its axis, to meet at the diſtance of the diameter of the ſphere of convexity; but that if both ſides of the lens be equally convex, the rays will have their focus at the diſtance of the radius of the circle, correſponding to that degree of convexity. But he did not inveſtigate any rule for the foci of lenſes unequally convex. He only ſays, in general, that they will fall ſomewhere in the medium, between the foci belonging to the two different degrees of convexity. It is to Cavallieri that we owe this inveſtigation. He laid down this rule: As the ſum of both the diameters is to one of them, ſo is the other to the diſtance of the focus. All theſe rules concerning convex lenſes are applicable to thoſe that are concave; with this difference, that the focus is on the contrary ſide of the glaſs, as will be particularly ſhown in the ſecond part of this treatiſe.

85
General reaſon of the effects of teleſcopes.

The principal effects of teleſcopes depend upon theſe plain maxims, viz. That objects appear larger in proportion to the angles which they ſubtend at the eye; and the effect is the ſame whether the pencils of rays, by which objects are viſible to us, come directly from the objects themſelves, or from any place nearer to the eye, where they may have been united ſo as to form an image of the object; becauſe they iſſue again from thoſe points where there is no real ſubſtance, in certain directions, in the ſame manner as they did from the correſponding points in the objects themſelves.

In fact, therefore, all that is effected by a teleſcope is, firſt, to make ſuch an image of a diſtant object, by means of a lens or mirror; and then to give the eye ſome aſſiſtance for viewing that image as near as poſſible: ſo that the angle which it ſhall ſubtend at the eye, may be very large, compared with the angle which the object itſelf would ſubtend in the ſame ſituation. This is done by means of an eye-glaſs, which ſo refracts the pencils of rays, as that they may afterwards be brought to their ſeveral foci by the natural humours of the eye. But if the eye was ſo formed as to be able to ſee the image with ſufficient diſtinctneſs at the ſame diſtance without any eye-glaſs, it would appear to him as much magnified as it does to another perſon who makes uſe of a glaſs for that purpoſe, though he would not in all caſes have ſo large a field of view.

If, inſtead of an eye-glaſs, an object, or the image of an object, be looked at through a ſmall hole in a thin plate or piece of paper, held cloſe to the eye, it may be viewed very near to the eye, and, at the ſame diſtance, the apparent magnitude of the object will be the ſame in both caſes. For if the hole be ſo ſmall as to admit but a ſingle ray from every diſtinct point of the object, theſe rays will fall upon the retina in as many other diſtinct points, and make a diſtinct image. They are only pencils or cones of rays, which have a ſenſible baſe, as the breadth of the pupil, that are capable, by their ſpreading on the retina, of producing an indiſtinct image. As very few rays, however, can be admitted through a ſmall hole, there will ſeldom be light ſufficient to view any object to advantage in this manner.

If no image be actually formed by the foci of the pencils without the eye, yet if, by the help of any eye-glaſs, the pencils of rays ſhall enter the pupil, juſt as they would have done [illegible] without the eye, the viſual angle will be the ſame as if an image had actually been formed in that place. Objects will not appear inverted through this teleſcope, becauſe the pencils which form the images of them, only croſs one another once, *viz.* at the object glaſs, as in natural viſion they do in the pupil of the eye.

86
Galilean teleſcope more difficult of conſtruction than others.

Such is the teleſcope that was firſt diſcovered and uſed by philoſophers; and it is remarkable that it ſhould be of a much more difficult conſtruction than ſome other kinds that have been invented ſince. The great inconvenience attending it is, that the field of view is exceedingly ſmall. For ſince the pencils of rays enter the eye very much diverging from one another, but few of them can be intercepted by the pupil, this inconvenience increaſes with the magnifying power of the teleſcope; ſo that philoſophers at this day cannot help wondering, that it was poſſible, with ſuch an inſtrument, for Galileo and others to have made the diſcoveries they did. It muſt have required incredible patience and addreſs. No other teleſcope, however, than this, was ſo much as thought of for many years after the diſcovery. Deſcartes, who wrote 30 years after, mentions no others as actually conſtructed, though Kepler had ſuggeſted ſome.

87
Teleſcopes improved by Kepler.

It is to this great man that we are indebted for the conſtruction of what we now call the *aſtronomical teleſcope*, being the beſt adapted for the purpoſe of viewing the heavenly bodies. The *rationale* of this inſtrument is explained, and the advantages of it are clearly pointed out, by this philoſopher, in his Catoptrics; but, what is very ſurpriſing, he never actually reduced his excellent theory into practice. Montucla conjectures, that the reaſon why he did not make trial of his new conſtruction was, his not being aware of the great increaſe of the field of view; ſo that being engaged in other purſuits, he might not think it of much conſequence to take any pains about the conſtruction of an inſtrument, which could do little more than anſwer the ſame purpoſe with thoſe of which he was already poſſeſſed. He muſt alſo have foreſeen, that the length of this teleſcope muſt have been greater in proportion to its magnifying power; ſo that it might appear to him to be upon the whole not quite ſo good a conſtruction as the former.

88 His method firſt put in practice by Scheiner.

It was not long, however, before Kepler's new ſcheme of a teleſcope was executed; and the firſt perſon who actually made an inſtrument of this conſtruction was Father Scheiner, who has given a deſcription of it in his *Roſa Urſina*, publiſhed in 1630. If, ſays, he, you inſert two ſimilar lenſes (that is, both convex) in a tûbe, and place your eye at a convenient diſtance, you will ſee all terreſtrial objects inverted, indeed, but magniſied and very diſtinct, with a conſiderable extent of view. He afterwards ſubjoins an account of a teleſcope of a different conſtruction, with two convex eye glaſſes, which again reverſes the images, and makes them appear in their natural poſition. This diſpoſition of the lenſes had alſo been pointed out by Kepler, but had not been reduced to practice by him, any more than the former. This conſtruction, however, anſwered the end but very imperfectly; and Father Rheita preſently after hit upon a better conſtruction, uſing three eye glaſſes inſtead of two. This got the name of the *terreſtrial teleſcope*, being chiefly uſed for terreſtrial objects.

The firſt and laſt of theſe conſtructions are thoſe which are now in common uſe. The proportion in which the firſt teleſcope magnifies, is as the focal length of the object-glaſs to that of the eye-glaſs.—The only difference between the Galilean teleſcope and the other is, that the pencils by which the extremities of any object are ſeen in this caſe, enter the eye diverging; whereas, in the other, they enter it converging; but if the ſphere of concavity in the eye-glaſs of the Galilean teleſcope be equal to the ſphere of convexity in the eye-glaſs of another teleſcope, their magnifying power will be the ſame. The concave eye-glaſs, however, being placed between the object-glaſs and its focus, the Galilean teleſcope will be ſhorter than the other, by twice the focal length of the eye-glaſs. Conſequently, if the length of the teleſcopes be the ſame, the Galilean will have the greater magnifying power.

89 Huygens greatly improves the teleſcopes of Scheiner and Rheita.

The invention of the teleſcope and microſcope having incited mathematicians to a more careful ſtudy of dioptrics, and this having ſoon become almoſt a perfect ſcience, by means of the diſcovery of Snellius, many different conſtructions were offered to the public. Huygens was particularly eminent for his ſyſtematic knowledge of the ſubject, and is the author of the chief improvements which have been made on all the dioptrical inſtruments till the time of Mr Dollond's diſcovery. He was well acquainted with the theory of aberration ariſing from the ſpherical figure of the glaſſes, and has ſhowed ſeveral ingenious methods of diminiſhing them by proper conſtructions of the eye-pieces. He firſt ſhowed the advantages of two eye-glaſſes on the aſtronomical teleſcope and double microſcope, and gave rules for this conſtruction, which both enlarges the field and ſhortens the inſtrument. Mr Dollond adapted his conſtruction to the terreſtrial teleſcope of De Rheita; and his five eye-glaſſes are nothing but the Huygenian eye-piece doubled. This conſtruction has been too haſtily given up by the artiſts of the preſent day for another, alſo of Mr Dollond's, of four glaſſes.

90 Viſion moſt diſtinct in the Galilean teleſcopes.

Viſion is more diſtinct in the Galilean teleſcope than in the other, owing perhaps in part to there being no intermediate image between the eye and the object. Beſides the eye-glaſs being very thin in the centre, the rays will be leſs liable to be diſtorted by irregularities in the ſubſtance of the glaſs. Whatever be the cauſe, we can ſometimes ſee Jupiter's ſatellites very clearly in a Galilean teleſcope not more than twenty inches or two feet long; when one of four or five feet, of the common ſort, will hardly make them viſible.

91 Binocular teleſcope.

The ſame Father Rheita, to whom we are indebted for the uſeful conſtruction of a teleſcope for land objects, invented a binocular teleſcope, which Father Cherubin, of Orleans, endeavoured to bring into uſe afterwards. It conſiſts of two teleſcopes faſtened together, and made to point to the ſame object. When this inſtrument is well fixed, the object appears larger, and nearer to the eye, when it is ſeen through both the teleſcopes, than through one of them only, though they have the very ſame magnifying power. But this is only an illuſion, occaſioned by the ſtronger impreſſion that two equal images, equally illuminated, make upon the eye. This advantage, however, is counterbalanced by the inconvenience attending the uſe of it.

92 Teleſcopes of Campani and Divini.

The firſt who diſtinguiſhed themſelves in grinding teleſcopic glaſſes were two Italians, Euſtachio Divini at Rome, and Campani at Bologna, whoſe fame was much ſuperior to that of Divini, or that of any other perſon of his time; though Divini himſelf pretended, that, in all the trials that were made with their glaſſes, his, of a great focal diſtance, performed better than thoſe of Campani, and that his rival was not willing to try them fairly, *viz*. with equal eye-glaſſes. It is generally ſuppoſed, however, that Campani really excelled Divini, both in the goodneſs and the focal length of his object-glaſſes. It was with teleſcopes made by Campani that Caſſini diſcovered the neareſt ſatellites of Saturn. They were made by the expreſs order of Louis XIV. and were of 86, 100, and 136 Pariſian feet focal length.

Campani ſold his lenſes for a great price, and took every poſſible method to keep his art of making them a ſecret. His laboratory was inacceſſible to all the world, till after his death; when it was purchaſed by Pope Benedict XIV. who made a preſent of it to the academy called the *Inſtitute*, eſtabliſhed in that city; and by the account which M. Fougeroux has given of what he could diſcover from it, we learn, that (except a machine, which M. Campani conſtructed, to work the baſons on which he ground his glaſſes) the goodneſs of his lenſes depended upon the clearneſs of his glaſs, his Venetian tripoli, the paper with which he poliſhed his glaſſes, and his great ſkill and addreſs as a workman. It was alſo the general opinion at Bologna, that he owed a great part of his reputation to the ſecrecy and air of myſtery which he affected; and that he made a great number of object-glaſſes which he rejected, ſhowing only thoſe that were very good. He made few lenſes of a very great focal diſtance; and having the misfortune to break one of 141 feet in two pieces, he took incredible pains to join the two parts together, which he did at length effectually, ſo that it was uſed as if it had been entire; but it is not probable that he would have taken ſo much pains about it, if, as he pretended, he could very eaſily have made another as good.

Sir Paul Neille, Dr Hooke ſays, made teleſcopes of 36 feet, pretty good, and one of 50, but not of proportional goodneſs. Afterwards Mr Reive firſt, and then Mr Cox, who were the moſt celebrated in England as grinders of optic glaſſes, made ſome good ones of 50 and 60 feet focal diſtance, and Mr Cox made one of 100; but how good, Dr Hooke could not aſſert.

Borelli alſo, in France, made object glaſſes of a great focal length, one of which he preſented to the Royal Society; but we do not find any particular account of their goodneſs.

93 Extraordinary object glaſs made by M. Auzout.

With reſpect to the focal length of teleſcopes, theſe and all others were far exceeded by M. Auzout, who made one object-glaſs of 600 feet focus; but he was never able to manage it, ſo as to make any uſe of it. Hartſocker is even ſaid to have made ſome of a ſtill greater focal length; but this ingenious mechanic, finding it impoſſible to make uſe of object-glaſſes the focal diſtance of which was much leſs than this, when they were encloſed in a tube, contrived a method of uſing them without a tube, by fixing them at the top of a tree, a high wall, or the roof a houſe.

94 Teleſcopes uſed without tubes.

Mr Huygens, who was alſo an excellent mechanic made conſiderable improvements in the method of uſing an object-glaſs without a tube. He placed it at the top of a very long pole, having previouſly encloſed it in a ſhort tube, which was made to turn in all directions by means of a ball and ſocket. The axis of this tube he could command with a fine ſilken ſtring, ſo as to bring it into a line with the axis of another ſhort tube which he held in his hand, and which contained the eye-glaſs. In this method he could make uſe of object-glaſſes of the greateſt magnifying power, at whatever altitude his object was, and even in the zenith, provided his pole was as long as his teleſcope; and to adapt it to the view of objects of different altitudes, he had a contrivance, by which he could raiſe or depreſs a ſtage that ſupported his object-glaſs at pleaſure.

M. De la Hire, made ſome improvement in this method of managing the object-glaſs, fixing it in the centre of a board, and not in a tube; but as it is not probable that this method will ever be made uſe of, ſince the diſcovery of both reflecting and achromatic teleſcopes, which are now brought to great perfection, and have even micrometers adapted to them, we ſhall not deſcribe this apparatus minutely; but ſhall only give a drawing of M. Huygens's pole, which, with a very ſhort explanation, will be ſufficient for the purpoſe. In fig. 1. *a* repreſents a pulley, by the help of which a ſtage *c*, *d*, *e*, *f*, (that ſupports the object-glaſs *k*, and the apparatus belonging to it), may be raiſed higher or lower at pleaſure, the whole being counterpoiſed by the weight *b*, faſtened to a ſtring *g*. *n*, Is a weight, by means of which the centre of gravity of the apparatus belonging to the object-glaſs is kept in the ball and ſocket, ſo that it may be eaſily managed by the ſtring *l u*, and its axis brought into a line with the eye-glaſs at *o*. When it was very dark, M. Huygens was obliged to make his object-glaſs viſible by a lantern, *y*, ſo conſtructed as to throw the rays of light in a parallel direction up to it.

Plate CCLIV.

The recollection of the incredible pains which philoſophers of the laſt age took in making obſervations, and the great expences they were obliged to be at for that purpoſe, ſhould make us ſenſible of the obligations we are under to ſuch men as Gregory, Newton, and Dollond, who have enabled us to get clearer and more ſatisfactory views of the remote parts of our ſyſtem, with much leſs labour and expence; and ſhould likewiſe make us more diligent and ſolicitous to derive all the advantages we poſſibly can from ſuch capital improvements.

95 Why dioptric teleſcopes muſt be made ſo long.

The reaſon why it is neceſſary to make the common dioptric teleſcopes ſo very long, is, that the length of them muſt be increaſed in no leſs a proportion than the duplicate of the increaſe of their magnifying power; ſo that, in order to magnify twice as much as before, with the ſame light and diſtinctneſs, the teleſcope muſt be lengthened four times; and to magnify thrice as much, nine times; and ſo on.

96 Of the apertures of refracting teleſcopes.

Before we mention the reflecting teleſcope, it muſt be obſerved, that M. Auzout, in a paper delivered to the Royal Society, obſerved, that the apertures which the object-glaſſes of refracting teleſcopes can bear with diſtinctneſs, are in about a ſub-duplicate proportion to their lengths; and upon this ſuppoſition he drew up a table of the apertures proper for object-glaſſes of a great variety of focal lengths, from 4 inches to 400 feet. Upon this occaſion, however, Dr Hooke obſerved, that the ſame glaſs will bear a greater or leſs aperture, according to the leſs or greater light of the object. If, for inſtance, he was viewing the ſun, or Venus, or any of the fixed ſtars, he uſed ſmaller apertures: but if he wanted to view the moon by daylight; or Saturn, Jupiter, or Mars, by night, he uſed a larger aperture.

But the merit of all theſe improvements was in a manner cancelled by the diſcovery of the much more commodious *reflecting teleſcope*. For a refracting teleſcope, even of 1000 feet focus, ſuppoſing it poſſible to be made uſe of, could not be made to magnify with diſtinctneſs more than 1000 times; whereas a reflecting teleſcope, not exceeding 9 or 10 feet will magnify 1200 times.

97 Hiſtory of the reflecting teleſcope.

"It muſt be acknowledged (ſays Dr Smith in his *Complete Syſtem of Optics*), that Mr James Gregory of Aberdeen was the firſt inventor of the reflecting teleſcope; but his conſtruction is quite different from Sir Iſaac Newton's, and not nearly ſo advantageous."

But, according to Dr Pringle, Merſennus was the man who entertained the firſt thought of a reflector. A teleſcope with ſpecula he certainly propoſed to the celebrated Deſcartes many years before Gregory's invention, though indeed in a manner ſo very unſatisfactory, that Deſcartes, who had given particular attention to the improvement of the teleſcope, was ſo far from approving the propoſal, that he endeavoured to convince Merſennus of its fallacy (B). Dr Smith, it

---

(B) *Lettres de Deſcartes*, Tom. II. printed at Paris in 1657, lett. 29. and 32. See this point diſcuſſed by two learned and candid authors, M. le Roy in the *Encyclopédie* under the article *Teleſcope*, and M. Montecula in *Hiſt. de Mathem.* Tom. II. p. 644.

it appears, had never peruſed the two letters of Deſcartes to Merſennus which briefly touch on that ſubject.

Again, As to his aſſertion, that Gregory's conſtruction was not nearly ſo advantageous as Newton's, it may be accounted for from his having ſet it down early in the compoſition of his work, and forgetting to qualify it afterwards, when, before the publication, he had received pretty ſure information to the contrary. Or perhaps he was influenced by the example of Dr Bradley, who had been a moſt ſucceſsful obſerver, and yet had always preferred the Newtonian teleſcope to the other. But we muſt certainly adjudge the ſuperiority to the latter, as that is now, and has been for ſeveral years paſt, the only inſtrument of the kind in requeſt.

Gregory, a young man of an uncommon genius, was led to the invention, in ſeeking to correct two imperfections of the common teleſcope: the firſt was its too great length, which made it leſs manageable; the ſecond, the incorrectneſs of the image. Mathematicians had demonſtr[illegible], that a pencil of rays could not be collected in [illegible] point by a ſpherical lens; and alſo, that the image tranſmitted by ſuch a lens would be in ſome degree incurvated. Theſe inconveniencies he believed would be obviated by ſubſtituting for the object glaſs a metallic ſpeculum, of a parabolic figure, to receive the image, and to reflect it towards a ſmall ſpeculum of the ſame metal: this again was to return the image to an eye-glaſs placed behind the great ſpeculum, which for that purpoſe was to be perforated in its centre. This conſtruction he publiſhed in 1663, in his *Optica Promota*. But as Gregory, by his own account, was endowed with no mechanical dexterity, nor could find any workman capable of realizing his invention, after ſome fruitleſs attempts in that way he was obliged to give up the purſuit: and probably, had not ſome new diſcoveries been made in light and colours, a refracting teleſcope would never more have been thought of, conſidering the difficulty of the execution, and the ſmall advantages that could accrue from it, deducible from the principles of optics that were then known.

But Newton, whoſe genius for experimental knowledge was equal to that for geometry, happily interpoſed, and ſaved this noble invention from well nigh periſhing in its infant ſtate. He likewiſe at an early period of life had applied himſelf to the improvement of the teleſcope; but imagining that Gregory's ſpecula were neither very neceſſary, nor likely to be executed, he began with proſecuting the views of Deſcartes, who aimed at making a more perfect image of an object, by grinding lenſes, not to the figure of a ſphere, but to that of one of the conic ſections. Now, whilſt he was thus employed, three years after Gregory's publication, he happened to take to the examination of the colours, formed by a priſm, and having by the means of that ſimple inſtrument diſcovered the different refrangibility of the rays of light, he then perceived that the errors of teleſcopes ariſing from that cauſe alone, were ſome hundred times greater than ſuch as were occaſioned by the ſpherical figure of lenſes. This circumſtance forced, as it were, Newton to fall into Gregory's track, and to turn his thoughts to reflectors. "The different refrangibility of the rays of light (ſays he, in a letter to Mr Oldenburg, ſecretary to the Royal Society, dated in Feb. 1672) made me take reflections into conſideration; and finding them regular, ſo that the angle of reflection of all ſorts of rays was equal to the angle of incidence, I underſtood that by their mediation optic inſtruments might be brought to any degree of perfection imaginable, providing a reflecting ſubſtance could be found which would poliſh as finely as glaſs, and reflect as much light as glaſs tranſmits, and the art of communicating to it a parabolic figure be alſo obtained. Amidſt theſe thoughts I was forced from Cambridge by the intervening plague, and it was more than two years before I proceeded further."

It appears, then, that if Newton was not the firſt inventor of the reflecting teleſcope, he was the main and effectual inventor. By the force of his admirable genius, he fell upon this new property of light; and thereby found, that all lenſes, of whatever figure, would be affected more or leſs with ſuch priſmatic aberrations of the rays as would be an inſuperable obſtacle to the perfection of a dioptric teleſcope.

It was towards the end of 1668, or in the beginning of the following year, when Newton being thus obliged to have recourſe to reflectors, and not relying on any artificer for making his ſpecula, ſet about the work himſelf, and early in the year 1672 completed two ſmall reflecting teleſcopes. In theſe he ground the great ſpeculum into a ſpherical concave; not but that he approved of the parabolic form propoſed by Gregory, though he found himſelf unable to accompliſh it. In the letter that accompanied one of theſe inſtruments which he preſented to the Society, he writes, "that though he then deſpaired of performing that work (to wit, the parabolic figure of the great ſpeculum) by geometrical rules, yet he doubted not but that the thing might in ſome meaſure be accompliſhed by mechanical devices."

Not leſs did the difficulty appear to find a metallic ſubſtance that would be of a proper hardneſs, have the feweſt pores, and receive the ſmootheſt poliſh; a difficulty in truth which he deemed almoſt unſurmountable, when he conſidered, that every irregularity in a reflecting ſurface would make the rays of light ſtray five or ſix times more out of their due courſe, than the like irregularities in a refracting one. In another letter, written ſoon after, he tells the ſecretary, "that he was very ſenſible that metal reflects leſs light than glaſs tranſmits; but as he had found ſome metallic ſubſtances to be more ſtrongly reflective than others, to poliſh better, and to be freer from tarniſhing than others, ſo he hoped that there might in time be found out ſome ſubſtances much freer from theſe inconveniencies than any yet known." Newton therefore laboured till he found a compoſition that anſwered in ſome degree, and left it to thoſe who ſhould come after him to find a better, and preſented a reflecting teleſcope to the Royal Society; from whom he received ſuch thanks as were due to ſo curious and ſo valuable a preſent. And Huygens, one of the greateſt geniuſes of the age, and himſelf a diſtinguiſhed improver of the refractor, no ſooner was informed by Mr Oldenburg of the diſcovery, than he wrote in anſwer, "that it was an admirable teleſcope; and that Mr Newton had well conſidered the advantage which a concave ſpeculum had above convex glaſſes in collecting the parallel rays, which according to his own calculation was very great: Hence that Mr Newton could give a far greater aperture to that ſpeculum than to an object glaſs of the ſame diſtance of focus, and conſequently much more magnify in his way than by an ordinary teleſcope: Beſides, that by the reflector he avoided an inconvenience inſeparable from object glaſſes, which was the obliquity of both their ſurfaces, which vitiated the refraction of the rays that paſs towards the ſides of the glaſs, and did more hurt than men were aware of: Again, That by the mere reflection of the metalline ſpeculum there were not ſo many rays loſt as in glaſſes, which reflected a conſiderable quantity by each of their ſurfaces, and beſides intercepted many of them by the obſcurity of their matter: That the main buſineſs would be, to find a matter for this ſpeculum that would bear as good and even a poliſh as glaſs. Laſtly, He believed that Mr Newton had not been without conſidering the advantage which a parabolic ſpeculum would have over a ſpherical one in this conſtruction; but had deſpaired, as he himſelf had done, of working other ſurfaces than ſpherical ones with due exactneſs." Huygens was not ſatisfied with thus expreſſing to the ſociety his high approbation of the late invention; but drew up a favourable account of the new teleſcope, which he cauſed to be publiſhed in the *Journal des Sçavans* for the year 1672, and by that channel it was ſoon known over Europe.

But how excellent ſoever the contrivance was; how well ſoever ſupported and announced to the public; yet whether it was that the artiſts were deterred by the difficulty and labour of the work, or that the diſcoveries even of a Newton were not to be exempted from the general fatality attending great and uſeful inventions, *the making a ſlow and vexatious progreſs to the authors;* the fact is, that, excepting an unſucceſsful attempt which the ſociety made, by employing an artificer to imitate the Newtonian conſtruction, but upon a larger ſcale, and a diſguiſed Gregorian teleſcope, ſet up by Caſſegrain abroad as a rival to Newton's, and that in theory only (for it was never put in execution by the author), no reflector was heard of for nearly half a century after. But when that period was elapſed, a reflecting teleſcope was at laſt produced to the world of the Newtonian conſtruction by Dr Hadley, which the author had the ſatisfaction to find executed in ſuch a manner as left no room to fear that the invention would any longer continue in obſcurity.

This memorable event was owing to the genius, dexterity, and application, of Mr Hadley the inventor of the reflecting quadrant, another moſt valuable inſtrument. The two teleſcopes which Newton had made were but ſix inches long, were held in the hand for viewing objects, and in power were compared to a ſix feet refractor; whereas Hadley's was above five feet long, was provided with a well-contrived apparatus for managing it, and equalled in performance the famous aërial teleſcope of Huygens of 123 feet in length. Excepting as to the manner of making the ſpecula, we have, in the Tranſactions of 1723, a complete deſcription, with a figure, of this teleſcope, together with that of the machine for moving it; but, by a ſtrange omiſſion, Newton's name is not once mentioned in that paper, ſo that any perſon not acquainted with the hiſtory of the invention, and reading that account only, might be apt to conclude that Hadley had been the ſole contriver of it.

The ſame celebrated artiſt, after finiſhing two teleſcopes of the Newtonian conſtruction, accompliſhed a third in the Gregorian way; but, it would ſeem, leſs ſucceſsfully, by Dr Smith's declaring ſo ſtrongly in favour of the other. Mr Hadley ſpared no pains to inſtruct Mr Molyneux and the reverend Dr Bradley; and when thoſe gentlemen had made a ſufficient proficiency in the art, being deſirous that theſe teleſcopes ſhould become more public, they liberally communicated to ſome of the principal inſtrument makers of London the knowledge they had acquired from him. Now ſuch ſcholars, as it is eaſy to imagine, ſoon advanced beyond their maſters, and completed reflectors by other and better methods than what had been taught them.

Certain it is, at leaſt, that Mr James Short, as early as the year 1734, had ſig[illegible] himſelf at Edinburgh by his work of this kind. Mr Maclaurin wrote that year to Dr Jurin, "that Mr Short, who had begun with making glaſs ſpecula, was then applying himſelf to improve the metallic; and that, by taking care of the figure, he was enabled to give them larger apertures than others had done; and that upon the whole they ſurpaſſed in perfection all that he had ſeen of other workmen." He added, "that Mr Short's teleſcopes were all of the Gregorian conſtruction; and that he had much improved that excellent invention." This character of excellence Mr Short maintained to the laſt; and with the more facility, as he had been well grounded both in the geometrical and philoſophical principles of optics, and upon the whole was a moſt intelligent perſon in whatever related to his profeſſion. It was ſuppoſed he had fallen upon a method of giving the parabolic figure to his great ſpeculum; a point of perfection that Gregory and Newton had wiſhed for, but deſpaired of attaining; and that Hadley had never, as far as we know, attempted, either in his Newtonian or Gregorian teleſcope. Mr Short indeed ſaid he had acquired that faculty, but never would tell by what peculiar means he effected it; ſo that the ſecret of working that configuration, whatever it was, as far as it then appeared, died with that ingenious artiſt. Mr Mudge, however, hath lately realized the expectation of Sir Iſaac Newton, who, above 100 years ago, preſaged that the public would one day poſſeſs a parabolic ſpeculum, not accompliſhed by mathematical rules, but by mechanical devices.

This was a *deſideratum*, but it was not the only want ſupplied by this gentleman: he has taught us likewiſe a better compoſition of metals for the ſpecula, how to grind them better, and how to give them a finer poliſh; and this laſt part (namely, the poliſh), he remarks, was the moſt difficult and eſſential of the whole operation. "In a word (ſays Sir John Pringle), I am of opinion, there is no optician in this great city (which hath been ſo long and ſo juſtly renowned for ingenious and dexterous makers of every kind of mathematical inſtruments) ſo partial to his own abilities as not to acknowledge, that, however ſome parts of the mechanical proceſs now diſcloſed might have been known before by individuals of the profeſſion, yet that Mr Mudge hath opened to them all ſome new and important lights, and upon the whole hath greatly improved the art of making reflecting teleſcopes."

98 Mr Edwards's improvements of the reflecting teleſcope.

The late reverend and ingenious John Edwards devoted much of his time to the improvement of reflecting teleſcopes, and brought them to ſuch perfection, that Dr Maſkelyne, the aſtronomer royal, found teleſcopes conſtructed by him to ſurpaſs in brightneſs, and other eſſentials, thoſe of the ſame ſize made by the beſt artiſts in London. The chief excellence of his teleſcopes ariſes from the compoſition, which, from various trials on metals and ſemimetals, he diſcovered for the ſpecula, and from the true parabolic figure, which, by long practice, he had found a method of giving them, preferable to any that was known before him. His directions for the compoſition of ſpecula, and for caſting, grinding, and poliſhing them, were publiſhed, by order of the commiſſioners of longitude, at the end of the Nautical Almanack for the year 1787. To the ſame almanack is alſo annexed his account of the cauſe and cure of the tremors which particularly affect reflecting teleſcopes more than refracting one, together with remarks on the ſaid tremors by Dr Maſkelyne. See Telescope.

99 Herſchel's improvements.

But in conſtructing reflecting teleſcopes of extraordinary magnifying powers, Dr Herſchel has diſplayed ſkill and ingenuity ſurpaſſing all his predeceſſors in this department of mechanics. He has made them from 7, 10, 20, to even 40 feet in length; and with the inſtrument of theſe latter dimenſions he is now employed in making diſcoveries in aſtronomy. Of its conſtruction, magnifying powers, and the curious collection of machinery by which it is ſupported and moved from one part of the heavens to another, accounts will be given under the word Telescope.

The greateſt improvement in *refracting* teleſcopes hitherto made public (c) is that of Mr Dollond, of which an account has already been given in a preceding ſection, wherein his diſcoveries in the ſcience of optics were explained. But, beſides the obligation we are under to him for correcting the aberration of the rays of light in the focus of object-glaſſes, ariſing from their different refrangibility, he made another conſiderable improvement in teleſcopes, viz. by correcting, in a great meaſure, both this kind of aberration, and alſo that which ariſes from the ſpherical form of lenſes by an expedient of a very different nature; viz. increaſing the number of eye-glaſſes.

100 Account of Mr Dollond's improvements

If any perſon, ſays he, would have the viſual angle of a teleſcope to contain 20 degrees, the extreme pencils of the field muſt be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glaſs, will cauſe an aberration from the figure, in proportion to the cube of that angle; but if two glaſſes are ſo proportioned and ſituated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and therefore, the aberration being in proportion to the cube of half the angle taken twice over, will be but a fourth part of that which is in proportion to the cube of the whole angle; becauſe twice the cube of 1 is but $\frac{1}{4}$ of the cube of 2; ſo the aberration from the figure, where two eye-glaſſes are rightly proportioned, is but a fourth of what it muſt unavoidably be, where the whole is performed by a ſingle eye-glaſs. By the ſame way of reaſoning, when the refraction is divided between three glaſſes, the aberration will be found to be but the ninth part of what would be produced from a ſingle glaſs; becauſe three times the cube of 1 is but one-ninth of the cube of 3. Whence it appears, that by increaſing the number of eye-glaſſes, the indiſtinctneſs which is obſerved near the borders of the field of a teleſcope may be very much diminiſhed, though not entirely taken away.

The method of correcting the errors ariſing from the different refrangibility of light is of a different conſideration from the former. For, whereas the errors from the figure can only be diminiſhed in a certain proportion according to the number of glaſſes, in this they may be entirely corrected by the addition of only one glaſs; as we find in the aſtronomical teleſcope, that two eye-glaſſes, rightly proportioned, will cauſe the edges of objects to appear free from colours, quite to the borders of the field. Alſo in the day teleſcope, where no more than two eye-glaſſes are abſolutely neceſſary for erecting the object, we find, that by the addition of a third, rightly ſituated, the colours, which would otherwiſe make the image confuſed, are entirely removed. This, however, is to be underſtood with ſome limitation: for though the different colours into which the extreme pencils muſt neceſſarily be divided by the edges of the eye-glaſſes, may in this manner be brought to the eye in a direction parallel to each other, ſo as, by the humours of the eye, to be made to converge to a point on the retina; yet, if the glaſſes exceed a certain length, the colours may be ſpread too wide to be capable of being admitted through the pupil or aperture of the eye; which is the reaſon, that in long teleſcopes, conſtructed in the common manner, with three eye-glaſſes, the field is always very much contracted.

Theſe conſiderations firſt ſet Mr Dollond on contriving how to enlarge the field, by increaſing the number of eye-glaſſes without any hinderance to the diſtinctneſs or brightneſs of the image; and though others had been about the ſame work before, yet, obſerving that ſome five-glaſs teleſcopes which were then made would admit of farther improvement, he endeavoured to conſtruct one with the ſame number of glaſſes in a

---

(c) Dr Blair's diſcovery, mentioned N° 19. will undoubtedly lead to improvements ſuperior to thoſe of Dollond; but as his memoir on the ſubject is not yet publiſhed, we feel not ourſelves at liberty to make longer extracts from it. The reader will ſee the whole in the Philoſophical Tranſactions of the Royal Society of Edinburgh, whenever that body ſhall be pleaſed to favour the public with a third volume of [illegible] arned labours.

better manner; which ſo far anſwered his expectations, as to be allowed by the beſt judges to be a conſiderable improvement on the former.

Encouraged by this ſucceſs, he reſolved to try if he could not make ſome farther enlargement of the field, by the addition of another glaſs, and by placing and proportioning the glaſſes in ſuch a manner as to correct the aberrations as much as poſſible, without any detriment to the diſtinctneſs: and at laſt he obtained as large a field as is convenient or neceſſary, and that even in the longeſt teleſcopes that can be made.

Theſe teleſcopes with ſix glaſſes having been well received, and ſome of them being gone into foreign parts, it ſeemed a proper time to the author to ſettle the date of his invention; on which account he drew up a letter, which he addreſſed to Mr Short, and which was read at the Royal Society, March 1. 1753 (D).

101 Mr Smith's propoſal to ſhorten teleſcopes.

Various other attempts were made about this time to ſhorten and otherwiſe improve teleſcopes. Among theſe we may juſt mention that of Mr Caleb Smith, who, after giving much attention to the ſubject, thought that he had found it poſſible to rectify the errors which ariſe from the different degrees of refrangibility, on the principle that their ſines of refraction, or rays differently refrangible, are to one another in a given proportion, when their ſines of incidence are equal; and the method which he propoſed for this purpoſe was to make the ſpeculums of glaſs inſtead of metal, the two ſurfaces having different degrees of concavity. But we do not find that this ſcheme was ever executed: nor is it probable, for reaſons which have been mentioned, that any advantage could be made of it.

102 Equatorial teleſcope, or portable obſervatory.

To Mr Short we are indebted for the excellent contrivance of an equatorial teleſcope, or, as he likewiſe called it, a *portable obſervatory*: for with it pretty accurate obſervations may be made with very little trouble, by thoſe who have no building adapted to the purpoſe. The inſtrument conſiſts of an ingenious piece of machinery, by the help of which a teleſcope mounted upon it may be directed to any degree of right aſcenſion or declination, ſo that the place of any of the heavenly bodies being known, they may be found without any trouble, even in the day time. Alſo, being made to turn parallel to the equator, any object is eaſily kept in view, or recovered, without moving the eye from its ſituation. By this inſtrument, Mr Short informs us, that moſt of the ſtars of the firſt and ſecond magnitude have been ſeen even at mid day, and the ſun ſhining bright; as alſo Mercury, Venus, and Jupiter. Saturn and Mars are not ſo eaſy to be ſeen, on account of the faintneſs of their light, except when the ſun is but a few hours above the horizon. This particular effect depends upon the teleſcope excluding almoſt all the light, except what comes from the object itſelf, and which might otherwiſe efface the impreſſion made by its weaker light upon the eye. Any teleſcope of the ſame magnifying power would have the ſame effect, could we be ſure of pointing it right. For the ſame reaſon, alſo, it is that ſtars are viſible in the day time from the bottom of a deep pit. Mr Ramſden has lately invented a *portable obſervatory* or *equatorial teleſcope*, which may perhaps ſuperſede the uſe of Mr Short's. See ASTRONOMY, N° 504.

103 How to obſerve the ſtars in the day time.

In order to enable us to ſee the fixed ſtars in the day time, it is neceſſary to exclude the extraneous light as much as poſſible. For this reaſon the greater magnifying power of any teleſcope is uſed, the more eaſily a fixed ſtar will be diſtinguiſhed in the day time; the light of the ſtar remaining the ſame in all magnifying powers of the ſame teleſcope, but the ground upon which it is ſeen becoming darker by increaſing the magnifying power; and the viſibility of a ſtar depends very much upon the difference between its own light and that of the ground upon which it is ſeen. A fixed ſtar will be very nearly equally viſible with teleſcopes of very different apertures, provided the magnifying power remains the ſame.

If a comet, or any other heavenly body, be viewed through this equatorial teleſcope, properly rectified, it is ſeen immediately by the help of the ſame machinery what is its true place in the heavens. Other aſtronomical problems may alſo be ſolved by it, with great eaſe and certainty.

104 Mr Æpinus's propoſal for bending the tubes of teleſcopes.

M. Æpinus propoſes to bend the tubes of long teleſcopes at right angles, fixing a plane mirror in the angle, in order to make them more commodious for viewing objects near the zenith of the obſerver; and he gives particular inſtructions how to make them in this form, eſpecially when they are furniſhed with micrometers. We are alſo informed that a little plane ſpeculum is ſometimes placed betwixt the laſt eye-glaſs and the eye in the reflecting teleſcopes, at an angle of 45°, for the ſame purpoſe.

105 Hiſtory of Microſcopes.

THE invention of MICROSCOPES was not much later than that of teleſcopes; and, according to Borellus, whoſe account we do not find to have been called in queſtion by any perſon, we are indebted for them to the ſame author, at leaſt to Z. Janſen, in conjunction with his ſon; and for this latter favour, we may perhaps, be conſidered as under more obligation to them than for the former, the microſcope having more various and extenſive uſes, with reſpect to philoſophy, than the teleſcope. In our ideas, however, it appears ſomething greater, and more extraordinary, to be able to ſee objects too diſtant to be perceived by the naked eye; than thoſe that are too near to be ſeen by us; and therefore there is more of the ſublime in the teleſcope than the microſcope. Theſe two inſtruments, though different in their application, are notwithſtanding very ſimilar; as both of them aſſiſt us in the diſcovery of objects that we muſt otherwiſe have remained unacquainted with, by enlarging the angle which they ſubtend at the eye.

The Janſens, however, have not always enjoyed, undiſturbed, that ſhare of reputation to which they ſeem to be entitled, with reſpect either to the teleſcope or the microſcope. The diſcovery of the latter, in particular, has generally been conſidered as more uncertain than that of the former. All that many writers ſay we can depend upon is, that microſcopes were firſt uſed in Germany about the year 1621. Others ſay poſitively, that this inſtrument was the contrivance of Cornelius

---

(D) This paragraph is extracted from this paper in the Tranſactions; but Dollond's improvement there deſcribed is not accompanied by any diagram. For a minute account of it, and of eye-pieces in general, ſee *Ludlam's Eſſays*

Cornelius Drebell, no philoſopher, but a man of curioſity and ingenuity, who alſo invented the thermometer.

According to Borellus, Zacharias Janſen and his ſon preſented the firſt microſcopes they had conſtructed to Prince Maurice, and Albert archduke of Auſtria. William Borell, who gives this account in a letter, to his brother Peter, ſays, that when he was ambaſſador in England, in 1619, Cornelius Drebell, with whom he was intimately acquainted, ſhowed him a microſcope, which he ſaid was the ſame the archduke had given him, and had been made by Janſen himſelf. This inſtrument was not ſo ſhort as they are generally made at preſent, but was ſix feet long, conſiſting of a tube of gilt copper, an inch in diameter, ſupported by three braſs pillars in the ſhape of dolphins, on a baſe of ebony, on which the ſmall objects were placed.

106 Microſcope made by Janſen.

This microſcope was evidently a compound one, or rather ſomething betwixt a teleſcope and a microſcope, what we ſhould now, perhaps chooſe to call a *megaloſcope*; ſo that it is poſſible that ſingle microſcopes might have been known, and in uſe, ſome time before; but perhaps nobody thought of giving that name to ſingle lenſes, though, from the firſt uſe of lenſes, they could not but have been uſed for the purpoſe of magnifying ſmall objects. In this ſenſe we have ſeen, that even the ancients were in poſſeſſion of microſcopes; and it appears from Jamblicus and Plutarch, quoted by Dr Rogers, that they gave ſuch inſtruments as they uſed for this purpoſe the name of *dioptra*. As ſpectacles were certainly in uſe long before the invention of teleſcopes, one can hardly help concluding, that lenſes muſt have been made ſmaller, and more convex, for the purpoſe of magnifying minute objects; eſpecially as the application of this kind of microſcope was nearly the ſame with that of a ſpectacle glaſs, both of them being held cloſe to the eye. At what time lenſes were made ſo ſmall as we now generally uſe them for magnifying in ſingle microſcopes, we have not found. But as this muſt neceſſarily have been done gradually, the only proper object of inquiry is the invention of the double or compound microſcope; and this is clearly given, by the evidence of Borellus above-mentioned, to Zacharias Janſen the inventor of the teleſcope, or his ſon.

The invention of compound microſcopes is claimed by the ſame Fontana who claimed the diſcovery of teleſcopes; and though he did not publiſh any account of this invention till the year 1646 (notwithſtanding he pretended to have made the diſcovery in 1618), Montucla, not having attended perhaps to the teſtimony of Borellus, is willing to allow his claim, as he thought there was no other perſon who ſeemed to have any better right to it.

107 By Divini.

Euſtachio Divini made microſcopes with two common object-glaſſes, and two plano-convex eye-glaſſes joined together on their convex ſides ſo as to meet in a point. The tube in which they were encloſed was as big as a man's leg, and the eye-glaſſes almoſt as broad as the palm of a man's hand. Mr Oldenburg, ſecretary to the Royal Society, received an account of this inſtrument from Rome, and read it at one of their meetings, Auguſt 6. 1668.

108 By Hartſoeker.

It was in this period that Hartſoeker improved ſingle microſcopes, by uſing ſmall globules of glaſs, made by melting them in the flame of a candle, inſtead of the lenſes which had before been made uſe of for that purpoſe. By this means he firſt diſcovered the *animalcula in ſemine maſculino*, which gave riſe to a new ſyſtem of generation. A microſcope of this kind, conſiſting of a globule of an inch $\frac{1}{10}$ in diameter, M. Huygens demonſtrated to magnify 100 times; and ſince it is eaſy to make them of leſs than half a line in diameter, they may be made to magnify 300 times. Were it not for the difficulty of applying objects to theſe magnifiers, the want of light, and the ſmall field of diſtinct viſion, they would certainly have been the moſt perfect of all microſcopes.

109 By Leeuwenhoek.

But no man diſtinguiſhed himſelf ſo much by microſcopical diſcoveries as the famous M. Leeuwenhoek, though he uſed only ſingle lenſes with ſhort foci, preferring diſtinctneſs of viſion to a large magnifying power.

M. Leeuwenhoek's microſcopes were all ſingle ones, each of them conſiſting of a ſmall double convex glaſs, ſet in a ſocket between two ſilver plates rivetted together, and pierced with a ſmall hole; and the object was placed on the point of a needle, ſo contrived as to be placed at any diſtance from the lens. If the objects were ſolid, he faſtened them with glue; and if they were fluid, or on other accounts required to be ſpread upon glaſs, he placed them on a ſmall piece of Muſcovy talc, or glaſs blown very thin; which he afterwards glued to his needle. He had, however, a different apparatus for viewing the circulation of the blood, which he could fix to the ſame microſcopes.

The greateſt part of his microſcopes M. Leeuwenhoek bequeathed to the Royal Society. They were contained in a ſmall Indian cabinet, in the drawers of which were 13 little boxes, or caſes, in each of which were two microſcopes, neatly fitted up in ſilver; and both the glaſs and the apparatus were made with his own hands.

The glaſs of all theſe lenſes is exceedingly clear, but none of them magnifies ſo much as thoſe globules which are frequently uſed in other microſcopes; but Mr Folkes, who examined them, thought that they ſhowed objects with much greater diſtinctneſs, which M. Leeuwenhoek principally valued. His diſcoveries, however, are to be aſcribed not ſo much to the goodneſs of his glaſſes, as to his great judgment, acquired by long experience, in uſing them. He alſo particularly excelled in his manner of preparing objects for being viewed to the moſt advantage.

Mr Baker, who alſo examined M. Leeuwenhoek's microſcopes, and made a report concerning them to the Royal Society, found that the greateſt magnifier among them enlarged the diameter of an object about 160 times, but that all the reſt fell much ſhort of that power; ſo he concluded that M. Leeuwenhoek muſt have had other microſcopes of a much greater magnifying power for many of his diſcoveries. And it appears, he ſays, by many circumſtances, that he had ſuch microſcopes.

It appears from M. Leeuwenhoek's writings, that he was not unacquainted with the method of viewing opaque objects by means of a ſmall concave reflecting mirror, which was afterwards improved by M. Lieberkuhn. For, after deſcribing his apparatus for viewing eels in glaſs tubes, he adds, that he had an inſtrument to which he ſcrewed a microſcope ſet in braſs, upon which microſcope he faſtened a little diſh of braſs, probably that his eye might be thereby aſſiſted to ſee objects better; for he ſays he had filed the braſs which was round his microſcope as bright as he could, that the light, while he was viewing objects, might be reflected from it as much as poſſible. This microſcope, with its diſh, is conſtructed upon principles ſo ſimilar to thoſe which are the foundation of our ſingle microſcope by reflection (ſee Microscope), that it may well be ſuppoſed to have given the hint to the ingenious inventor of it, provided he ever attended to it.

110 Wilſon's microſcope.

In 1702, Mr Wilſon made ſeveral ingenious improvements in the method of uſing ſingle magnifiers, for the purpoſe of viewing tranſparent objects; and his microſcope, which is alſo a neceſſary part of the ſolar microſcope, is in very general uſe at this day. (See Microscope, ſect. 1.)

111 Adams's method of making globules for large magnifiers.

In 1710, Mr Adams gave to the Royal Society the following account of his method of making ſmall globules for large magnifiers. He took a piece of fine window-glaſs, and cut it with a diamond into as many lengths as he thought proper, not exceeding $\frac{1}{8}$ of an inch in breadth; then, holding one of them between the fore-finger and thumb of each hand over a very fine flame, till the glaſs began to ſoften, he drew it out till it was as fine as a hair, and broke; then putting each of the ends into the pureſt part of the flame, he had two globules preſently, which he could make larger or leſs at pleaſure. If they were held a long time in the flame, they would have ſpots in them, ſo that he drew them out preſently after they became round. The ſtem he broke off as near to the globule as he could, and lodging the remainder between the plates, in which holes were drilled exactly round, the microſcope, he ſays, performed to admiration. Through theſe magnifiers, he ſays, that the ſame thread of very fine muſlin appeared three or four times bigger than it did in the largeſt of Mr Wilſon's magnifiers.

112 Temporary microſcopes by Mr Grey.

The ingenious Mr Grey hit upon a very eaſy expedient to make very good temporary microſcopes, at a very little expence. They conſiſt of nothing but very ſmall drops of water, taken up with the point of a pin, and put into a ſmall hole made in a piece of metal. Thoſe globules of water, do not, indeed, magnify ſo much as thoſe which are made of glaſs of the ſame ſize, becauſe the refractive power of water is not ſo great; but the ſame purpoſe will be anſwered nearly as well by making them ſomewhat ſmaller.

The ſame ingenious perſon, obſerving that ſmall heterogeneous particles encloſed in the glaſs of which microſcopes are made, were much magnified when thoſe glaſſes were looked through, thought of making his microſcopes of water that contained living animalcula, to ſee how they would look in this new ſituation; and he found his ſcheme to anſwer even beyond his utmoſt expectation, ſo that he could not even account for their being magnified ſo much as they were: for it was much more than they would have been magnified if they had been placed beyond the globule, in the proper place for viewing objects. But Montucla obſerves, that, when any object is encloſed within this ſmall tranſparent globule, the hinder part of it acts like a concave mirror, provided they be ſituated between that ſurface and the focus; and that, by this means, they are magnified above $3\frac{1}{2}$ times more than they would have been in the uſual way.

113 Dr Barker's reflecting microſcope.

After the happy execution of the reflecting teleſcope, it was natural to expect that attempts would alſo be made to render a ſimilar ſervice to microſcopes. Accordingly we find two plans of this kind. The firſt was that of Dr Robert Barker. His inſtrument differs in nothing from the reflecting teleſcope, excepting the diſtance of the two ſpeculums, in order to adapt it to thoſe pencils of rays which enter the microſcope diverging; whereas they come to the teleſcope from very diſtant objects nearly parallel to each other.

This microſcope is not ſo eaſy to manage as the common ſort. For viſion by reflection, as it is much more perfect, ſo it is far more difficult than that by refraction. Nor is this microſcope ſo uſeful for any but very ſmall or tranſparent objects. For the object, being between the ſpeculum and image, would, if it were large and opaque, prevent a due reflection.

114 Dr Smith's reflecting microſcope ſuperior to all others.

Dr Smith invented a double reflecting microſcope, of which a theoretical and practical account is given in the remarks on the ſecond volume of his Syſtem of Optics. Through ſome of thoſe incidents to which the conducting of a work ſo multifarious as ours is always liable, this inſtrument was omitted under the article Microscope. As it is conſtructed on principles eſſentially different from all others, and, in the opinion of the ableſt judges whom we have conſulted, incomparably ſuperior to them all, the reader will not be ill pleaſed with the following practical deſcription, though it appears not perhaps in its moſt proper place.

Plate CCCLIV.

Fig. 2. is a ſection of this microſcope, where ABC and *abc* are two ſpecula, the former concave, and the latter convex, encloſed within the tube DEFG. The ſpeculum ABC, is perforated like the ſpeculum of a Gregorian teleſcope; and the object to be magnified is ſo placed between the centre and principal focus of that ſpeculum, that the rays flowing from it to ABC are reflected towards an image *pq*. But before they are united in that image they are received by the convex ſpeculum *abc*, and thence reflected through the hole BC in the vertex of the concave to a ſecond image $\pi\kappa$, to be viewed through an eye-glaſs *l*. The object may either be ſituated between the two ſpecula, or, which is perhaps better, between the principal focus and vertex *c* of the convex ſpeculum *abc*, a ſmall hole being made in its vertex for the incident rays to paſs through. When the microſcope is uſed, let the object be included between two little round plates of Muſcovy glaſs, fixed in a hole of an oblong braſs plate *mn*, intended to ſlide cloſe to the back ſide of the convex ſpeculum: which muſt therefore be ground flat on that ſide, and ſo thin that the object may come preciſely to its computed diſtance from the vertex of the ſpeculum. The ſlider muſt be kept tight to the back of the metal by a gentle ſpring. The diſtance of the object being thus determined once for all, diſtinct viſion to different eyes, and through different eye-glaſſes, muſt be procured by a gentle motion of the little tubes that contain theſe glaſſes. Theſe tubes muſt be made in the uſual form of thoſe that belong to Sir Iſaac Newton's reflecting teleſcope, (ſee Telescope), having a ſmall hole in the middle of each plate, at the ends of the tube, ſituated exactly in each focus of the glaſs; the uſe of theſe holes and plates is to limit the viſible area, and hinder any ſtraggling rays from entering the eye. To the tube of the eye-glaſs is faſtened the arm *g*, on which the adjuſting ſcrew turns. A ſimilar arm *u* is attached to the fixed tube X, in which the neck of the ſcrew turns; and by turning the button *y*, the eye tube is moved farther from or nearer to the object, by which means different ſorts of eyes obtain diſtinct viſion.

The rays which flow from the object directly through the hole in the concave ſpeculum and through the eye-glaſs, by mixing with the reflected rays, would dilute the image on the retina, and therefore muſt be intercepted. This is done by a very ſimple contrivance. The little hole in the convex ſpeculum is ground conical as in the figure; and a conical ſolid P, of which the baſe is larger than the orifice in the back of the convex ſpeculum, ſupported on the ſlender pillar PQ, is ſo placed as to intercept all the *direct rays*, from the eye-glaſs. All the tubes are ſtrongly blacked on their inſides, and ſo is the conical ſolid, to hinder all reflection of rays from theſe objects upon the convex ſpeculum. The little baſe [illegible], of the ſolid ſhould be made concave, that whatever light it may ſtill reflect, may be thrown back upon the object; and its backſide being conical and blacked all over, will either abſorb or laterally diſperſe any ſtraggling rays which the concave ſpeculum may ſcatter upon it, and ſo prevent their coming to the eye-glaſs.

Notwithſtanding the interpoſition of this conical ſolid, yet when the eye-glaſs is taken out, diſtant objects may be diſtinctly ſeen through the microſcope, by rays reflected from the metals, and diverging upon the eye from an image behind the convex ſpeculum. But this mixture of foreign rays with thoſe of the object, which is common to all kinds of microſcopes in viewing tranſparent objects, is uſually prevented by placing before the object a thick double convex lens L, to collect the ſky light exactly from the object. This lens ſhould be juſt ſo broad as to ſubtend the oppoſite angle to that which the concave ſpeculum ſubtends at the object. The annular frame of the lens muſt be very narrow, and connected to the microſcope by two or three ſlender wires or blades, whoſe planes produced may paſs through the object, and intercept from it as little ſky light as poſſible.

This is not the place for explaining the principles of this microſcope, or demonſtrating its ſuperiority over moſt others; nor are ſuch explanation and demonſtration neceſſary. Its excellence, as well as the principles upon which it is conſtructed, will be perceived by the reader, when he has made himſelf maſter of the laws of refraction and reflection as laid down in the enſuing part of this article.

115
Solar microſcope, and that for opaque objects.

In 1738 or 1739, M. Lieberkuhn made two capital improvements in microſcopes, by the invention of the *ſolar microſcope*, and the *microſcope for opaque objects*. When he was in England in the winter of 1739, he ſhowed an apparatus of his own making, for each of theſe purpoſes, to ſeveral gentlemen of the Royal Society, as well as to ſome opticians, particularly Mr Cuff in Fleet-ſtreet, who took great pains to improve them.

The microſcope for opaque objects remedies the inconvenience of having the dark ſide of an object next the eye. For by means of a concave ſpeculum of ſilver, highly poliſhed, in the centre of which a magnifying lens is placed, the object is ſo ſtrongly illuminated that it may be examined with all imaginable eaſe and pleaſure. A convenient apparatus of this kind, with four different ſpeculums and magnifiers of different powers, was brought to perfection by Mr Cuff.

M. Lieberkuhn made conſiderable improvements in his ſolar microſcope, particularly in adapting it to the view of opaque objects; but in what manner this end was effected, M. Æpinus, who was highly entertained with the performance, and who mentions the fact, was not able to recollect; and the death of the ingenious inventor prevented his publiſhing any account of it himſelf. M. Æpinus invites thoſe perſons who came into the poſſeſſion of M. Lieberkuhn's apparatus to publiſh an account of this inſtrument; but it doth not appear that his method was ever publiſhed.

This improvement of M. Lieberkuhn's induced M. Æpinus himſelf to attend to the ſubject; and by this means he produced a very valuable improvement in this inſtrument. For by throwing the light upon the foreſide of any object by means of a mirror, before it is tranſmitted through the object lens, all kinds of objects are equally well repreſented by it.

116
Reflected light introduced into the microſcope and magic lantern.

M. Euler propoſed a ſcheme to introduce viſion by reflected light into the magic lantern and ſolar microſcope, by which many inconveniences to which thoſe inſtruments are ſubject might be avoided. For this purpoſe, he ſays, that nothing is neceſſary but a large concave mirror, perforated as for a teleſcope; and that the light be ſo ſituated, that none of it may paſs directly through the perforation, ſo as to fall on the images of the objects upon the ſcreen. He propoſes to have four different machines, for objects of different ſizes; the firſt for thoſe of ſix feet long, the ſecond for thoſe of one foot, the third for thoſe of two inches, and the fourth for thoſe of two lines; but it is needleſs to be particular in the deſcription of theſe, as more perfect inſtruments are deſcribed under the article MICROSCOPE.

Several improvements were made in the apparatus to the ſolar microſcope, as adapted to view opaque objects, by M. Zeiher, who made one conſtruction for the larger kind of objects, and another for the ſmall ones.

117
Mr Martin's improvement in the ſolar microſcope.

Mr Martin having conſtructed a ſolar microſcope of a larger ſize than common, for his own uſe, the illuminating lens being 4½ inches in diameter, and all the other parts of the inſtrument in proportion, found, that by the help of an additional part, which he does not deſcribe, he could ſee even opaque objects very well. If he had made the lens any larger, he was aware that the heat produced at the focus would have been too great for the generality of objects to bear. The expence of this inſtrument, he ſays, does not much exceed the price of the common ſolar microſcope.

118
Di Torre's extraordinary magnifying microſcope.

The ſmalleſt globules, and conſequently the greateſt magnifiers, for microſcopes, that have yet been executed, were made by T. Di Torre of Naples, who, in 1765, ſent four of them to the Royal Society. The largeſt of them was only two Paris points in diameter, and it was ſaid to magnify the diameter of an object 640 times. The ſecond was the ſize of one Paris point, and

119 Could not be uſed by Mr Baker.

and the third was no more than half of a Paris point, or the 144th part of an inch in diameter, and was ſaid to magnify the diameter of an object 2560 times. One of theſe globules was wanting when they came into the hands of Mr Baker, to whoſe examination they were referred by the Royal Society. This gentleman, ſo famous for his ſkill in microſcopes, and his extraordinary expertneſs in managing them, was not able to make any uſe of theſe. With that which magnifies the leaſt, he was not able to ſee any object with ſatisfaction; and he concludes his account with expreſſing his hopes only, that, as his eyes had been much uſed to microſcopes, they were not injured by the attention he had given to them, though he believed there were few perſons who would not have been blinded by it.

The conſtruction of a teleſcope with ſix eye-glaſſes led M. Euler to a ſimilar conſtruction of microſcopes, by introducing into them ſix lenſes, one of which admits of ſo ſmall an aperture, as to ſerve, inſtead of a diaphragm, to exclude all foreign light, though, as he ſays, it neither leſſens the field of view, nor the brightneſs of objects.

120 Difficulties attending the conſtruction of dioptric inſtruments.

The improvement of all dioptric inſtruments is greatly impeded by inequalities in the ſubſtance of the glaſs of which they are made; but though many attempts have been made to make glaſs without that imperfection, none of them have been hitherto quite effectual. M. A. D. Merklein, having found ſome glaſs which had been melted when a building was on fire, and which proved to make excellent object-glaſſes for teleſcopes, concluded that its peculiar goodneſs aroſe from its not having been diſturbed when it was in a fluid ſtate; and therefore he propoſed to take the metal out of the furnace in iron veſſels, of the ſame form that was wanted for the glaſs; and after it had been perfectly fluid in thoſe veſſels, to let it ſtand to cool, without any diſturbance. But this is not always found to anſwer.

PART I. THEORY OF OPTICS.

THIS part of the ſcience contains all that hath been diſcovered concerning the various motions of the rays of light, either through different mediums, or when reflected from different ſubſtances in the ſame medium. It contains alſo the *rationale* of every thing which hath been diſcovered with regard to viſion; the optical deceptions to which we are liable; and, in ſhort, ought to give the reaſon of all the known optical phenomena.—The ſcience is commonly divided into three parts, viz. Dioptrics, which contain the laws of refraction, and the phenomena depending upon them; Catoptrics, which contain the laws of reflection, and the phenomena which depend on them; and, laſtly, Chromatics, which treat of the phenomena of colour. But this definition is of no uſe in a treatiſe of Optics, as moſt of the phenomena depend both on refraction and reflection, colour itſelf not excepted. For this reaſon, though we have given detached articles under the words DIOPTRICS, CATOPTRICS, and CHROMATICS; we have reſerved to this place the explanation of the laws of reflection and refraction, by which all optical phenomena may be accounted for.

SECT. I. *Of the properties of Light in general.*

121 Different opinions concerning the nature of light.

UNDER the article LIGHT we have given ſome account of the controverſies concerning its nature. The opinions of philoſophers may, in general, be arranged under theſe two: 1. That the phenomena of viſion and illumination are produced by the undulations of an elaſtic fluid, much in the ſame manner as ſound is produced by the undulations of air. This opinion was firſt offered to the public by Deſcartes, and afterwards by Mr Huygens, and has lately been revived by M. Euler, who has endeavoured to explain the phenomena upon mechanical principles.—2. That the phenomena of viſion are produced by the motion and action of matter emitted from the ſhining body with immenſe velocity, moving uniformly in ſtraight lines, and acted on by other bodies; ſo as to be reflected, refracted, or inflected, in various ways, by means of forces which act on it in the ſame manner as on other inert matter. Sir Iſaac Newton has ſhown, in the moſt incontrovertible manner, the total diſſimilarity between the phenomena of viſion and the legitimate conſequences of the undulations of an elaſtic fluid. All M. Euler's ingenious and laborious diſcuſſions have not removed Newton's objections in the ſmalleſt degree. Sir Iſaac adopts the vulgar opinion, therefore, making light of the difficulties objected to it, becauſe none of them are inconſiſtent with the eſtabliſhed principles of mechanics, and are merely difficulties of conception to limited faculties like ours. We need not deſpair of being able to decide, by experiment, which of theſe opinions is neareſt to the truth; becauſe there are phenomena where the reſult ſhould be ſenſibly different in the two hypotheſes. At preſent, we ſhall content ourſelves with giving ſome account of the legitimate conſequences of the vulgar opinion as modified by Sir Iſaac Newton, viz. that light conſiſts of ſmall particles emitted with very great velocity, and attracted or repelled by other bodies at very ſmall diſtances.

122 Light iſſues in ſtraight lines from each point in a luminous ſurface.

Every viſible body emits or reflects inconceivably ſmall particles of matter from each point of its ſurface, which iſſue from it continually (not unlike ſparks from a coal) in ſtraight lines and in all directions. Theſe particles entering the eye, and ſtriking upon the retina, (a nerve expanded on the back part of the eye to receive their impulſes), excite in our minds the idea of light. And as they differ in ſubſtance, denſity, velocity, or magnitude, they produce in us the ideas of different colours; as will be explained in its proper place.

That the particles which conſtitute light are exceedingly ſmall, appears from hence, viz. that if a hole be made through a piece of paper with a needle, rays of light from every object on the farther ſide of it are capable of paſſing through it at once without the leaſt confuſion; for any one of thoſe objects may as clearly be ſeen through it, as if no rays paſſed through it from any of the reſt. Further, If a candle is lighted, and there be no obſtacle in the way to obſtruct the progreſs of its rays, it will fill all the ſpace within two miles of it every way with luminous particles, before it has loſt the leaſt ſenſible part of its ſubſtance thereby.

That theſe particles proceed from every point of the ſurface of a viſible body, and in all directions, is clear from hence, *viz.* becauſe wherever a ſpectator is placed with regard to the body, every point of that part of the ſurface which is turned towards him is viſible to him. That they proceed from the body in right lines, we are aſſured, becauſe juſt ſo many and no more will be intercepted in their paſſage to any place by an interpoſed object, as that object ought to intercept, ſuppoſing them to come in ſuch lines.

The velocity with which they proceed from the ſurface of the viſible body is no leſs ſurpriſing than their minuteneſs; the method whereby philoſophers eſtimate their ſwiftneſs, is by obſervations made on the eclipſes of Jupiter's ſatellites; which eclipſes appear to us about ſeven minutes ſooner than they ought to do by calculation, when the earth is placed between the ſun and him, that is, when we are neareſt to him; and as much later, when the ſun is between him and us, at which time we are fartheſt from him; from whence it is concluded, that they require about ſeven minutes to paſs over a ſpace equal to the diſtance between the ſun and us, which is about 95,000,000 of miles.

A ſtream of theſe particles iſſuing from the ſurface of a viſible body in one and the ſame direction, is called a *ray of light*.

As rays proceed from a viſible body in all directions, they neceſſarily become thinner and thinner, continually ſpreading themſelves as they paſs along into a larger ſpace, and that in proportion to the ſquares of their diſtances from the body; that is, at the diſtance of two ſpaces, they are four times thinner than they are at one; at the diſtance of three ſpaces, nine times thinner, and ſo on; the reaſon of which is, becauſe they ſpread themſelves in a twofold manner, *viz.* upwards and downwards, as well as ſidewiſe.

The particles of light are ſubject to the laws of attraction of coheſion, like other ſmall bodies; for if a ray of light be made to paſs by the edge of a knife, it will be diverted from its natural courſe, and be inflected towards the edge of the knife. The like inflection happens to a ray when it enters obliquely into a denſer or rarer ſubſtance than that in which it was before, in which caſe it is ſaid to be refracted; the laws of which refraction are the ſubject of the following ſection.

Sect. II. *Of Refraction.*

123
Refraction defined.

Light, when proceeding from a luminous body, without being reflected from any opaque ſubſtance, or inflected by paſſing very near one, is invariably found to proceed in ſtraight lines, without the leaſt deviation. But if it happens to paſs obliquely from one medium to another, it always leaves the direction it had before, and aſſumes a new one; and this change of courſe is called its *refraction*. After having taken this new direction, it then proceeds invariably in a ſtraight line till it meets with a different medium, when it is again turned out of its courſe. It muſt be obſerved, however, that though by this means we may cauſe the rays of light make any number of angles in their courſe, it is impoſſible for us to make them deſcribe a curve, except in one ſingle caſe, namely, where they paſs through a medium, the denſity of which uniformly either increaſes or decreaſes. This is the caſe with the light of the celeſtial bodies, which paſſes downwards through our atmoſphere, and likewiſe with that which is reflected upwards through it by terreſtrial objects. In both theſe caſes, it deſcribes a curve of the hyperbolic kind; but at all other times it proceeds in ſtraight lines, or in what may be taken for ſtraight lines without any ſenſible error.

124
In what caſe the rays of light deſcribe a curve.

§ 1. *The cauſe of Refraction, and the law by which it is performed.*

125
Phenomena of refraction ſolved by an attractive power in the medium.

The phenomena of refraction are explained by an attractive power in the medium through which light paſſes, in the following manner: All bodies being endowed with an attractive force, which is extended to ſome diſtance beyond their ſurfaces; when a ray of light paſſes out of a rarer into a denſer medium (if this latter has a greater attractive force than the former, as is commonly the caſe), the ray, juſt before its entrance, will begin to be attracted towards the denſer medium; and this attraction will continue to act upon it, till ſome time after it has entered the medium; and therefore, if a ray approaches a denſer medium in a direction perpendicular to its ſurface, its velocity will be continually accelerated during its paſſage through the ſpace in which that attraction exerts itſelf; and therefore, after it has paſſed that ſpace, it will move on, till it arrives at the oppoſite ſide of the medium, with a greater degree of velocity than it had before it entered. So that in this caſe its velocity only will be altered. Whereas, if a ray enters a denſer medium obliquely, it will not only have its velocity augmented thereby, but its direction will become leſs oblique to the ſurface. Juſt as when a ſtone is thrown downwards obliquely from a precipice, it falls to the ſurface of the ground in a direction nearer to a perpendicular one, than that with which it was thrown from the hand. From hence we ſee a ray of light, in paſſing out of a rarer into a denſer medium, is refracted towards the perpendicular; that is, ſuppoſing a line drawn perpendicularly to the ſurface of the medium, through the point where the ray enters, and extended both ways, the ray in paſſing through the ſurface is refracted or bent towards the perpendicular line; or, which is the ſame thing, the line which it deſcribes by its motion after it has paſſed through the ſurface, makes a leſs angle with the perpendicular, than the line it deſcribed before. All which may be illuſtrated in the following manner.

Plate CCCLIV.

Let us ſuppoſe firſt, that the ray paſſes out of a vacuum into the denſer medium ABCD (fig. 3.), and that the attractive force of each particle in the medium is extended from its reſpective centre to a diſtance equal to that which is between the lines AB and EF, or AB and GH; and let KL be the path deſcribed by a ray of light in its progreſs towards the denſer medium. This ray, when it arrives at L, will enter the attractive forces of thoſe particles which lie in AB the ſurface of the denſer medium, and will therefore ceaſe to proceed any longer in the right line KLM, but will be diverted from its courſe by being attracted towards the

Cauſe of Refraction.

the line AB, and will begin to deſcribe the curve LN paſſing through the ſurface AB in ſome new direction, as OQ; thereby making a leſs angle with a line, as PR, drawn perpendicularly through the point N, than it would have done had it proceeded in its firſt direction KLM.

Farther: Whereas, we have ſuppoſed the attractive force of each particle to be extended through a ſpace equal to the diſtance between AB and EF, it is evident that the ray, after it has entered the ſurface, will ſtill be attracted downwards, till it has arrived at the line EF; for, till that time, there will not be ſo many particles above it which will attract it upwards, as below, that will attract it downwards. So that after it has entered the ſurface at N, in the direction OQ, it will not proceed in that direction, but will continue to deſcribe a curve, as NS; after which it will proceed ſtraight on towards the oppoſite ſide of the medium, being attracted equally every way; and therefore will at laſt proceed in the direction XST, ſtill nearer the perpendicular PR than before.

Now if we ſuppoſe ABZY not to be a vacuum, but a rarer medium than the other, the caſe will ſtill be the ſame; but the ray will not be ſo much refracted from its rectilineal courſe, becauſe the attraction of the particles of the upper medium being in a contrary direction to that of the attraction of thoſe in the lower one, the attraction of the denſer medium will in ſome meaſure be deſtroyed by that of the rarer.

On the contrary, when a ray paſſes out of a denſer into a rarer medium, if its direction be perpendicular to the ſurface of the medium, it will only loſe ſomewhat of its velocity, in paſſing through the ſpaces of attraction of that medium (that is, the ſpace wherein it is attracted more one way than it is another). If its direction be oblique, it will continually recede from the perpendicular during its paſſage, and by that means have its obliquity increaſed, juſt as a ſtone thrown up obliquely from the ſurface of the earth increaſes its obliquity all the time it riſes. Thus, ſuppoſing the ray TS paſſing out of the denſer medium ABCD into the rarer ABZY, when it arrives at S it will begin to be attracted downwards, and ſo will deſcribe the curve SNL, and then proceed in the right line LK; making a larger angle with the perpendicular PR, than the line TSX in which it proceeded during its paſſage through the other medium.

We may here make a general obſervation on the forces which produce this deviation of the rays of light from their original path. They ariſe from the joint action of all the particles of the body which are ſufficiently near the particle of light; that is, whoſe diſtance from it is not greater than the line AE or GA; and therefore the whole force which acts on a particle in its different ſituations between the planes GH and EF, follows a very different law from the force exerted by one particle of the medium.

The ſpace through which the attraction of coheſion of the particles of matter is extended is ſo very ſmall, that in conſidering the progreſs of a ray of light out of one medium into another, the curvature it deſcribes in paſſing through the ſpace of attraction is generally neglected; and its path is ſuppoſed to be bent, or, in the uſual terms, the ray is ſuppoſed to be refracted only in the point where it enters the denſer medium.

Cauſe of Refraction.

Now the line which a ray deſcribes before it enters a denſer or a rarer medium, is called the *incident ray*: that which it deſcribes after it has entered, is the *refracted ray*.

The angle comprehended between the incident ray and the perpendicular, is the *angle of incidence*; and that between the refracted ray and the perpendicular, is the *angle of refraction*.

There is a certain and immutable law or rule, by which refraction is always performed; and that is this: Whatever inclination a ray of light has to the ſurface of any medium before it enters it, the degree of refraction will always be ſuch, that the proportion between the ſine of the angle of its incidence, and that of the angle of its refraction, will always be the ſame in that medium.

Plate CCCLIV.

To illuſtrate this: Let us ſuppoſe ABCD (fig. 4.) to repreſent a rarer, and ABEF a denſer medium: let GH be a ray of light paſſing through the firſt and entering the ſecond at H, and let HI be the refracted ray: then ſuppoſing the perpendicular PR drawn through the point H, on the centre H, and with any radius, deſcribe the circle APBR; and from G and I, where the incident and refracted rays cut the circle, let fall the lines GK and IL, perpendicularly upon the line PR; the former of theſe will be the ſine of the angle of incidence, the latter of refraction. Now if in this caſe the ray GH is ſo refracted at H, that GK is double or triple, &c. of IL, then, whatever other inclination the ray GH might have had, the ſine of its angle of incidence would have been double or triple, &c. to that of its angle of refraction. For inſtance, had the ray paſſed in the line MH before refraction, it would have paſſed in ſome line as HN afterwards, ſo ſituated that MO ſhould have been double or triple, &c. of NQ.

When a ray paſſes out of a vacuum into air, the ſine of the angle of incidence is found to be to that of refraction as 100036 to 100000.

When it paſſes out of air into water, as about 4 to 3.

When out of air into glaſs, as about 17 to 11.

When out of air into a diamond, as about 5 to 2.

This relation of the ſine of the angle of incidence to that of refraction, which is a propoſition of the moſt extenſive uſe in explaining the optical phenomena on phyſical or mechanical principles, may be demonſtrated in the following eaſy and familiar manner.

Lemma I. The augmentations or diminutions of the ſquares of the velocities produced by the uniform action of accelerating or retarding forces, are proportional to the forces, and to the ſpaces along which they act, jointly, or are proportional to the products of the forces multiplied by the ſpaces.

Let two bodies be uniformly accelerated from a ſtate of reſt in the points A *a*, along the ſpaces AB, *a b*, fig. 5. by the accelerated forces F *f*, and let AC, *a c*, be ſpaces deſcribed in equal times; it is evident, from what has been ſaid under the articles Gravity and Acceleration, that becauſe theſe ſpaces are deſcribed with motions uniformly accelerated, AC and *ac* are reſpectively the halves of the ſpaces which would be uniformly deſcribed during the ſame time with the velocities acquired at C and *c*, and are therefore meaſures of theſe velocities. And as theſe velocities are uniformly acquired in equal times, they are meaſures of the accelerating forces. Therefore $AC : ac = F : f$. Alſo, from the nature of uniformly accelerated motion, the ſpaces are proportional to the ſquares of the acquired velocities. Therefore, (uſing the ſymbols $\surd^2 C$, $\surd^2 c$, &c. to expreſs the ſquares of the velocities at $C\,c$, &c.) we have

$$\surd^2 B : \surd^2 C = AB : AC$$
$$\surd^2 C : \surd^2 c = AC^2 : ac^2$$
$$\surd^2 c : \surd^2 b = ac : ab$$

Therefore, by equality of compound ratios

$$\surd^2 B : \surd^2 b = AB \times AC : ab \times ac, = AB \times F : ab \times f.$$

And in like manner $\surd^2 D : \surd^2 d = AD \times F : ad \times f$; and $\surd^2 B - \surd^2 D : \surd^2 b - \surd^2 d = BD \times F : bd \times f$. Q. E. D.

Corol. If the forces are as the ſpaces inverſely, the augmentations or diminutions of the ſquares of the velocities are equal.

Remark. If DB, *db*, be taken extremely ſmall, the products $BD \times F$ and $bd \times f$ may be called the momentary actions of the forces, or the momentary increments of the ſquares of the velocities. It is uſually expreſſed, by the writers on the higher mechanics, by the ſymbol $f\dot{s}$, or fds, where f means the accelerating force, and $\dot{s}$ or ds means the indefinitely ſmall ſpace along which it is uniformly exerted. And the propoſition is expreſſed by the fluxionary equation $f\dot{s} = v\dot{v}$, becauſe $v\dot{v}$ is half the increment of v^2, as is well known.

Plate CCCLIV. fig. 6. *Lemma* 2. (being the 39th propoſition of the firſt book of Newton's Principia.) If a particle of matter, moving with any velocity along the line AC, be impelled by an accelerating or retarding force, acting in the ſame or in the oppoſite direction, and if the intenſity of the force in the different points B, F, H, C, &c. be as the ordinates BD, FG, &c. to the line DGE, the areas BFGD, BHKD, &c. will be as the changes made on the ſquare of the velocity at B, when the particle arrives at the points F, H, &c.

For let BC be divided into innumerable ſmall portions, of which let FH be one, and let the force be ſuppoſed to act uniformly, or to be of invariable intenſity during the motion along FH; draw GI perpendicular to HK: It is evident that the rectangle FHIG will be as the product of the accelerating force by the ſpace along which it acts, and will therefore expreſs the momentary increment of the ſquare of the velocity. (Lemma 1.) The ſame may be ſaid of every ſuch rectangle. And if the number of the portions, ſuch as FH, be increaſed, and their magnitude diminiſhed without end, the rectangles will ultimately occupy the whole curvilineal area, and the force will be continually varying in its intenſity. The curvilineal areas will therefore be as the finite changes made on the ſquare of the velocity, and the propoſition is demonſtrated.

Corol. The whole change made on the ſquare of the velocity, is equal to the ſquare of that velocity which the accelerating force would communicate to the particle by impelling it along BC from a ſtate of reſt in B. For the area BCED will ſtill expreſs the ſquare of this velocity, and it equally expreſſes the change made on the ſquare of *any* velocity wherewith the particle may paſs through the point B, and is independent on the magnitude of that velocity.

Remark. The figure is adapted to the caſe where the forces all conſpire with the initial motion of the particle, or all oppoſe it, and the area expreſſes an augmentation or a diminution of the ſquare of the initial velocity. But the reaſoning would have been the ſame, although, in ſome parts of the line BC, the forces had conſpired with the initial motion, and in other parts had oppoſed it. In ſuch a caſe, the ordinates which expreſs the intenſity of the forces muſt lie on different ſides of the abſciſſa BC, and that part of the area which lies on one ſide muſt be conſidered as negative with reſpect to the other, and be ſubtracted from it. Thus, if the forces are repreſented by the ordinates of the dotted curve line DH*e*, which croſſes the abſciſſa in H, the figure will correſpond to the motion of a particle, which, after moving uniformly along AB, is ſubjected to the action of a variable accelerating force during its motion along BH, and the ſquare of its initial velocity is increaſed by the quantity BHD; after which it is retarded during its motion along HC, and the ſquare of its velocity in H is diminiſhed by a quantity HC*e*. Therefore the ſquare of the initial velocity is changed by a quantity BHD—HC*e*, or HC*e*—BHD.

This propoſition is perhaps the moſt important in the whole ſcience of mechanics, being the foundation of every application of mechanical theory to the explanation of natural phenomena. No traces of it are to be found in the writings of philoſophers before the publication of Newton's Principia, although it is aſſumed by John Bernoulli and other detractors from Newton's greatneſs as an elementary truth, without any acknowledgment of their obligations to its author. It is uſually expreſſed by the equation $f\dot{s} = v\dot{v}$ and $\int f\dot{s} = v^2$, *i. e.* the ſum of the momentary actions is equal to the whole or finite increment of the ſquare of the velocity.

PROPOSITION.

126 The ratio of the ſine of incidence to the ſine of refraction.

When light paſſes obliquely into or out of a tranſparent ſubſtance, it is refracted ſo that the ſine of the angle of incidence is to the ſine of the angle of refraction in the conſtant ratio of the velocity of the refracted light to that of the incident light.

Let ST, KR (fig. 7.), repreſent two planes (parallel to, and equidiſtant from, the refracting ſurface XY) which bound the ſpace in which the light, during its paſſage, is acted on by the refracting forces, as explained in N° 125. The intenſity of the refracting forces being ſuppoſed equal at equal diſtances from the bounding planes, though anyhow different at different diſtances from them, may be repreſented by the ordinates T*a*, *nq*, *pr*, *c*R, &c. of the curve *a b n p c*, of which the form muſt be determined from obſervation, and may remain for ever unknown. The phenomena of inflected light ſhow us that it is attracted by the refracting ſubſtance at ſome diſtances, and repelled at others.

Let the light, moving uniformly in the direction AB, enter the refracting ſtratum at B. It will not proceed in that direction, but its path will be incurvated upwards, while acted on by a repulſive force, and downwards, while impelled by an attractive force. It will deſcribe ſome curvilineal path B*do* CDE, which AB touches in B, and will finally emerge from the refracting ſtratum at E, and move uniformly in a ſtraight line EF, which touches the curve in E. If, through *b*, the interſection of the curve of forces with its abſciſſa, we draw *b o*, cutting the path of the light in *o*, it is evident that this path will be concave upwards between B and *o*, and concave downwards between *o* and E. Alſo, if the initial velocity of the light has been ſufficiently ſmall, its path may be ſo much bent upwards, that in ſome point *d* its direction may be parallel to the bounding planes. In this caſe it is evident, that being under the influence of a repulſive force, it will be more bent upwards, and it will deſcribe *d f*, equal and ſimilar to *d* B, and emerge in an angle *g f s*, equal to ABG. In this caſe it is reflected, making the angle of reflection equal to that of incidence. By which it appears how reflection, refraction, and inflection, are produced by the ſame forces and performed by the ſame laws.

But let the velocity be ſuppoſed ſufficiently great to enable the light to penetrate through the refracting ſtratum, and emerge from it in the direction EF; let AB and EF be ſuppoſed to be deſcribed in equal times: They will be proportional to the initial and final velocities of the light. Now, becauſe the refracting forces *muſt* act in a direction perpendicular to the refracting ſurface (ſince they ariſe from the joint action of all the particles of a homogeneous ſubſtance which are within the ſphere of mutual action), they cannot affect the motion of the light eſtimated in the direction of the refracting ſurface. If, therefore, AG be drawn perpendicular to ST, and FK to KR, the lines GB, EK, muſt be equal, becauſe they are the motions AB, EF, eſtimated in the direction of the planes. Draw now EL parallel to AB. It is alſo equal to it. Therefore EL, EF, are as the initial and final velocities of the light. But EF is to EL as the ſine of the angle ELK to the ſine of the angle EFK; that is, as the ſine of the angle ABH to the ſine of the angle FEI; that is, as the ſine of the angle of incidence to the ſine of the angle of refraction.

By the ſame reaſoning it will appear that light, moving in the direction and with the velocity FE, will deſcribe the path EDB, and will emerge in the direction and with the velocity BA.

Let another ray enter the refracting ſtratum perpendicularly at B, and emerge at Q. Take two points N, P, in the line BQ, extremely near to each other, ſo that the refracting forces may be ſuppoſed to act uniformly along the ſpace NP: draw NC, PD, parallel to ST, CM perpendicular to DP, and MO perpendicular to CD, which may be taken for a ſtraight line. Then, becauſe the forces at C and N are equal, by ſuppoſition they may be repreſented by the equal lines CM and NP. The force NP is wholly employed in accelerating the light along NP; but the force CM being tranſverſe to the motion BD, is but partly ſo employed, and may be conceived as ariſing from the joint action of the forces CO, OM, of which CO only is employed in accelerating the motion of the light, while OM is employed in incurvating its path. Now it is evident, from the ſimilarity of the triangles DCM, MCO, that DC : CM=CM : CO, and that $DC \times CO = CM \times CM = NP \times NP$. But $DC \times CO$ and $NP \times NP$ are as the products of the ſpaces by the accelerating forces, and expreſs the momentary increments of the ſquares of the velocities at C and N. (Lemma 1.) Theſe increments, therefore, are equal. And as this muſt be ſaid of every portion of the paths BCE and BNQ, it follows that the whole increment of the ſquare of the initial velocity produced in the motion along BCE, is equal to the increment produced in the motion along BNQ. And, becauſe the initial velocities were equal in both paths, their ſquares were equal. Therefore the ſquares of the final velocities are alſo equal in both paths, and the final velocities themſelves are equal. The initial and final velocities are therefore in a conſtant ratio, whatever are the directions; and the ratio of the ſines of the angles of incidence and refraction being the ratio of the velocities of the refracted and incident light, by the former caſe of Prop. 1. is alſo conſtant.

Remark. The augmentation of the ſquare of the initial velocity is equal to the ſquare of the velocity which a particle of light would have acquired, if impelled from a ſtate of reſt at B along the line BQ. (Corol. of the Lemma 2.), and is therefore independent on the initial velocity. As this augmentation is expreſſed by the curvilineal area *a* T *b n p c* R, it depends both on the intenſity of the refracting forces, expreſſed by the ordinates, and on the ſpace through which they act, viz. TR. Theſe circumſtances ariſe from the nature of the tranſparent ſubſtance, and are characteriſtic of that ſubſtance. Therefore, to abbreviate language, we ſhall call this the *ſpecific velocity*.

This ſpecific velocity is eaſily determined for any ſubſtance in which the refraction is obſerved, by drawing L *i* perpendicular to EL, meeting in *i* the circle deſcribed with the radius EF. For E *i* being equal to EF, will repreſent the velocity of the refracted light, and EL repreſent the velocity of the incident light, and $Ei^2 = EL^2 + Li^2$, and therefore Li^2 is the augmentation of the ſquare of the initial velocity, and L *i* is the ſpecific velocity.

It will now be proper to deduce ſome corollaries from theſe propoſitions, tending to explain the chief phenomena of refraction.

127 The motion of light accelerated or retarded by refraction.

1. When light is refracted towards the perpendicular to the refracting ſurface, it is accelerated; and it is retarded when it is refracted from the perpendicular. In the firſt caſe, therefore, it muſt be conſidered as having been acted on by forces conſpiring (in part at leaſt) with its motion, and *vice verſa*. Therefore, becauſe we ſee that it is always refracted towards the perpendicular, when paſſing from a void into any tranſparent ſubſtance, we muſt conclude that it is, on the whole, attracted by that ſubſtance. We muſt draw the ſame concluſion from obſerving, that it is refracted from the perpendicular in its paſſage out of any tranſparent ſubſtance whatever into a void. It has been attracted backwards by that ſubſtance.

This acceleration of light in refraction is contrary to the opinion of thoſe philoſophers who maintain, that illumination is produced by the undulation of an elaſtic medium. Euler attempts to prove, by mechanical laws, that the velocities of the incident and refracted light are proportional to the ſines of incidence and refraction, while our principles make them in this

C of
Retion.

Cauſe of
Refraction.

ratio inverſely. Boſcovich propoſed a fine experiment for deciding this queſtion. The aberration of the fixed ſtars ariſes from the combination of the motion of light with the motion of the teleſcope by which it is obſerved. Therefore this aberration ſhould be greater or leſs when obſerved by means of a teleſcope filled with water, according as light moves ſlower or ſwifter through water than through air. He was miſtaken in the manner in which the concluſion ſhould be drawn from the obſervation made in the form preſcribed by him: and the experiment has not yet been made in a convincing manner; becauſe no fluid has been found of ſufficient tranſparency to admit of the neceſſary magnifying power. It is an experiment of the greateſt importance to optical ſcience.

2. If the light be moving within the tranſparent ſubſtance, and if its velocity (eſtimated in a direction perpendicular to the ſurface) do not exceed the ſpecific velocity of that ſubſtance, it will not emerge from it, but will be reflected backwards in an angle equal to that of its incidence. For it muſt be obſerved, that in the figure of laſt propoſition, the exceſs of the ſquare of EF above the ſquare of EL, is the ſame with the exceſs of the ſquare of KF above the ſquare of KL. Therefore the ſquare of the ſpecific velocity is equal to the augmentation or diminution of the ſquare of the perpendicular velocity. If therefore the initial perpendicular velocity FK (fig. 8.) be preciſely equal to the ſpecific velocity, the light will juſt reach the farther ſide of the attracting ſtratum, as at B, where its perpendicular velocity will be completely extinguiſhed, and its motion will be in the direction BT. But it is here under the influence of forces tending towards the plane KR, and its motion will therefore be ſtill incurvated towards it; and it will deſcribe a curve BD equal and ſimilar to EB, and finally emerge back from the refracting ſtratum into the tranſparent ſubſtance in an angle RDA equal to KEF.

Plate
CCCLIV.

If the direction of the light be ſtill more oblique, ſo that its perpendicular velocity is leſs than the ſpecific velocity, it will not reach the plane ST, but be reflected as ſoon as it has penetrated ſo far that the ſpecific velocity of the part penetrated (eſtimated by the compounding part of the area of forces) is equal to its perpendicular velocity. Thus the ray *f* E will deſcribe the path E*d*D*a* penetrating to *bd*, ſo that the correſponding area of forces *abce* is equal to the ſquare of *fk*, its perpendicular velocity.

The extreme brilliancy of dew drops and of jewels had often excited the attention of philoſophers, and it always appeared a difficulty how light was reflected at all from the poſterior ſurface of tranſparent bodies. It afforded Sir Iſaac Newton his ſtrongeſt argument againſt the uſual theory of reflection, viz. that it was produced by impact on ſolid elaſtic matter. He was the firſt who took notice of the total reflection in great obliquities; and very properly aſked how it can be ſaid that there is any impact in this caſe, or that the reflecting impact ſhould ceaſe at a particular obliquity?

128
Rays at a certain obliquity are wholly reflected by tranſparent ſubſtances.

It muſt be acknowledged that it is a very curious circumſtance, that a body which is perfectly tranſparent ſhould ceaſe to be ſo at a certain obliquity; that a great obliquity ſhould not hinder light from paſſing from a void into a piece of glaſs; but that the ſame obliquity ſhould prevent it from paſſing from the glaſs into a void. The fineſt experiment for illuſtrating the fact is, to take two pieces of mirror-glaſs, not ſilvered, and put them together with a piece of paper between them, forming a narrow margin all round to keep them apart. Plunge this apparatus into water. When it is held nearly parallel to the ſurface of the water, every thing at the bottom of the veſſel will be ſeen clearly through the glaſſes; but when they are turned ſo as to be inclined about 50 degrees, they will intercept the light as much as if they were plates of iron. It will be proper to ſoak the paper in varniſh, to prevent water from getting between the glaſſes.

120
The brilliant cut in diamonds produces total reflection.

What is called the brilliant cut in diamonds, is ſuch a diſpoſition of the poſterior facets of the diamond, that the light is made to fall upon them ſo obliquely that none of it can go through, but all is reflected. To produce this effect in the greateſt poſſible degree is a matter of calculation, and merits the attention of the lapidary. When diamonds are too thin to admit of this form, they are cut in what is called the roſe faſhion. This has a plain back, and the facets are all on the front, and ſo diſpoſed as to refract the rays into ſufficient obliquities, to be ſtrongly reflected from the poſterior plane. Doublets are made by cutting one thin diamond roſe faſhion, and another ſimilar one is put behind it, with their plane ſurfaces joined. Or, more frequently, the outſide diamond has the anterior facets of the brilliant, and the inner has the form of the inner part of a brilliant. If they be joined with very pure and ſtrongly refracting varniſh, little light is reflected from the ſeparating plane, and their brilliancy is very conſiderable, though ſtill inferior to a true and deep brilliant. If no varniſh be uſed, much of the light is reflected from the flat ſide, and the effect of the poſterior facets is much diminiſhed. But doublets might be conſtructed, by making the touching ſurfaces of a ſpherical form (of which the curvature ſhould have a due proportion to the ſize of the ſtone), that would produce an effect nearly equal to that of the moſt perfect brilliant.

130
Refraction diminiſhes as the incident velocity increaſes.

3. Since the change made on the ſquare of the velocity of the incident light is a conſtant quantity, it follows, that the refraction will diminiſh as the velocity of the incident light increaſes. For if L *i* in fig. 7. be a conſtant quantity, and EL be increaſed, it is evident that the ratio of E*i*, or its equal EF, to EL will be diminiſhed, and the angle LEF, which conſtitutes the refraction, will be diminiſhed. The phyſical cauſe of this is eaſily ſeen: When the velocity of the incident light is increaſed, it employs leſs time in paſſing through the refracting ſtratum or ſpace between the planes ST and KR, and is therefore leſs influenced by the refracting forces. A ſimilar effect would follow if the tranſparent body were moving with great velocity towards the luminous body.

Some naturaliſts have accounted for the different refrangibility of the differently coloured rays, by ſuppoſing that the red rays move with the greateſt rapidity, and they have determined the difference of original velocity which would produce the obſerved difference of refraction. But this difference would be obſerved in the eclipſes of Jupiter's ſatellites. They ſhould be ruddy at their emerſions, and be ſome ſeconds before they attain their pure whiteneſs; and

Cauſe of Refraction.

they ſhould become bluiſh immediately before they vaniſh in immerſions. This is not obſerved. Beſides, the difference in refrangibility is much greater in flint glaſs than in crown glaſs, and this would require a proportionally greater difference in the original velocities. The explanation therefore muſt be given up.

131 The refraction of a ſtar greater in the evening than in the morning.

It ſhould follow, that the refraction of a ſtar which is in our meridian at ſix o'clock in the evening ſhould be greater than that of a ſtar which comes on the meridian at ſix in the morning; becauſe we are moving away from the firſt, and approaching to the laſt. But the difference is but $\frac{1}{10000}$ of the whole, and cannot be obſerved with ſufficient accuracy in any way yet practiſed. A form of obſervation has been propoſed by Dr Blair profeſſor of practical aſtronomy in the univerſity of Edinburgh, which promiſes a very ſenſible difference of refraction. It is alſo to be expected, that a difference will be obſerved in the refraction of the light from the eaſt and weſtern ends of Saturn's ring. Its diameter is about 26 times that of the earth, and it revolves in 10h. 32′; ſo that the velocity of its edge is about $\frac{1}{10000}$ of the velocity of the ſun's light. If therefore the light be reflected from it according to the laws of perfect elaſticity, or in the manner here explained, that which comes to us from the weſtern extremity will move more ſlowly than that which comes from the eaſtern extremity in the proportion of 2500 to 2501. And if Saturn can be ſeen diſtinctly after a refraction of 30° through a priſm, the diameter of the ring will be increaſed one half in one poſition of the teleſcope, and will be as much diminiſhed by turning the teleſcope half round its axis; and an intermediate poſition will exhibit the ring of a diſtorted ſhape. This experiment is one of the moſt intereſting to optical ſcience, as its reſult will be a ſevere touchſtone of the theories which have been attempted for explaining the phenomena on mechanical principles.

If the tail of a comet be impelled by the rays of the ſun, as is with great probability ſuppoſed by Euler and others, the light by which its extreme parts are ſeen by us muſt have its velocity greatly diminiſhed, being reflected by particles which are moving away from the ſun with immenſe rapidity. This may perhaps be diſcovered by its greater aberration and refrangibility.

132 All light ſubject to the ſame

As common day light is nothing but the ſun's light reflected from terreſtrial bodies, it is reaſonable to expect that it will ſuffer the ſame refraction. But nothing but obſervation could aſſure us that this would be the caſe with the light of the ſtars; and it is rather ſurpriſing that the velocity of their light is the ſame with that of the ſun's light. It is a circumſtance of connexion between the ſolar ſyſtem and the reſt of the univerſe. It was as little to be looked for on the light of terreſtrial luminaries. If light be conceived as ſmall particles of matter emitted from bodies by the action of accelerating forces of any kind, the vaſt diverſity which we obſerve in the conſtitution of ſublunary bodies ſhould make us expect differences in this particular. Yet it is found, that the light of a candle, of a glow-worm, &c. ſuffers the ſame refraction, and conſiſts of the ſame colours. This circumſtance is adduced as an argument againſt the theory of emiſſion. It is thought more probable that this ſameneſs of velocity is owing to the nature of the medium, which determines the frequency of its undulations and the velocity of their propagation.

e of R tion.

Law refracti. when ht paſſes of one tiſ- parent b dy into other cor. tiguous to it.

4. When two tranſparent bodies are contiguous, the light in its paſſage out of the one into the other will be refracted towards or from the perpendicular, according as the refracting forces of the ſecond are greater or leſs than thoſe of the firſt, or rather according as the area expreſſing the ſquare of the ſpecific velocity is greater or leſs. And as the difference of theſe areas is a determined quantity, the difference between the velocity in the medium of incidence and the velocity in the medium of refraction, will alſo be a determined quantity. Therefore the ſine of the angle of incidence will be in a conſtant ratio to the ſine of the angle of refraction; and this ratio will be compounded of the ratio of the ſine of incidence in the firſt medium to the ſine of refraction in a void; and the ratio of the ſine of incidence in a void to the ſine of refraction in the ſecond medium. If therefore a ray of light, moving through a void in any direction, ſhall paſs through any number of media bounded by parallel planes, its direction in the laſt medium will be the ſame as if it had come into it from a void.

5. It alſo follows from theſe propoſitions, that if the obliquity of incidence on the poſterior ſurface of a tranſparent body be ſuch, that the light ſhould be reflected back again, the placing a maſs of the ſame or of another medium in contact with this ſurface, will cauſe it to be tranſmitted, and this the more completely, as the added medium is more denſe or more refractive; and the reflection from the ſeparating ſurface will be the more vivid in proportion as the poſterior ſubſtance is leſs denſe or of a ſmaller refractive power. It is not even neceſſary that the other body be in contact; it is enough if it be ſo near that thoſe parts of the refracting ſtrata which are beyond the bodies interfere with or coincide with each other.

All theſe conſequences are agreeable to experience. The brilliant reflection from a dew drop ceaſes when it touches the leaf on which it reſts: The brilliancy of a diamond is greatly damaged by moiſture getting behind it: The opacity of the combined mirror plates, mentioned in the ſecond corollary, is removed by letting water get between them: A piece of glaſs is diſtinctly or clearly ſeen in air, more faintly when immerſed in water, ſtill more faintly amidſt oil of olives, and it is hardly perceived in ſpirits of turpentine. Theſe phenomena are incompatible with the notion that reflection is occaſioned by impact on ſolid matter, whether of the tranſparent body, or of any ether or other fancied fluid behind it; and their perfect coincidence with the legitimate conſequences of the aſſumed principles, is a ſtrong argument in favour of the truth of thoſe principles.

134 An objection to the Newtonian theory of refraction.

It is worth while to mention here a fact taken notice of by Mr Beguelin, and propoſed as a great difficulty in the Newtonian theory of refraction. In order to get the greateſt poſſible refraction, and the ſimpleſt meaſure of the refracting power at the anterior ſurface of any tranſparent ſubſtance, Sir Iſaac Newton enjoins us to employ a ray of light falling on the ſurface *quam obliquiſſimè*. But Mr Beguelin found, that when the obliquity of incidence in glaſs was about

89°

89° 50′, no light was refracted, but that it was wholly reflected. He alſo obſerved, that when he gradually increaſed the obliquity of incidence on the poſterior ſurface of the glaſs, the light which emerged laſt of all did not ſkim along the ſurface, making an angle of 90° with the perpendicular, as it ſhould do by the Newtonian theory, but made an angle of more than ten minutes with the poſterior ſurface. Alſo, when he began with very great obliquities, ſo that all the light was reflected back into the glaſs, and gradually diminiſhed the obliquity of incidence, the firſt ray of light which emerged did not ſkim along the ſurface, but was raiſed about 10 or 15 minutes.

135
Shown to be the neceſſary conſequence of that theory, and of courſe a confirmation of it.

But all theſe phenomena are neceſſary conſequences of our principles, combined with what obſervation teaches us concerning the forces which bodies exert on the rays of light. It is evident, from the experiments of Grimaldi and Newton, that light is both attracted and repelled by ſolid bodies. Newton's ſagacious analyſis of theſe experiments diſcovered ſeveral alternations of actual inflection and deflection; and he gives us the preciſe diſtance from the body when ſome of theſe attractions end and repulſion commences; and the moſt remote action to be obſerved in his experiments is repulſion. Let us ſuppoſe this to be the caſe, although it be not abſolutely neceſſary. Let us ſuppoſe that the forces are repreſented by the ordinates of a curve *a b n p c* (fig. 7.) which croſſes the abſciſſa in *b*. Draw *b o* parallel to the refracting ſurface. When the obliquity of incidence of the ray A B has become ſo great, that its path in the glaſs, or in the refracting ſtratum, does not cut, but only touches the line *o b*, it can penetrate no further, but is totally reflected; and this muſt happen in all greater obliquities. On the other hand, when the ray LE, moving within the glaſs, has but a very ſmall perpendicular velocity, it will penetrate the refracting ſtratum no further than till this perpendicular velocity is extinguiſhed, and its path becomes parallel to the ſurface, and it will be reflected back. As the perpendicular velocity increaſes by diminiſhing the obliquity of incidence, it will penetrate farther; and the laſt reflection will happen when it penetrates ſo far that its path touches the line *o b*. Now diminiſh the obliquity by a ſingle ſecond; the light will get over the line *o b*, will deſcribe an arch *o d* B concave upwards, and will emerge in a direction BA, which does not ſkim the ſurface, but is ſenſibly raiſed above it. And thus the facts obſerved by M. Beguelin, inſtead of being an objection againſt this theory, afford an argument in its favour.

Plate CCCLIV.

136
Euler's theory of undulation contrary to fact;

7. Thoſe philoſophers who maintain the theory of undulation, are under the neceſſity of connecting the diſperſive powers of bodies with their mean refractive powers. M. Euler has attempted to deduce a neceſſary difference in the velocity of the rays of different colours from the different frequency of the undulations, which he aſſigns as the cauſe of their different colorific powers. His reaſoning on this ſubject is of the moſt delicate nature, and unintelligible to ſuch as are not completely maſter of the infiniteſimal calculus of partial differences, and is unſatisfactory to ſuch as are able to go through its intricacies. It is contradicted by fact. He ſays, and indeed to be conſiſtent he muſt ſay it, that muſical ſounds which differ greatly in acuteneſs are propagated through the air with different velocities: but one of the ſmalleſt bells in the chimes of St Giles's church in Edinburgh was ſtruck againſt the rim of the very deep-toned bell on which the hours are ſtruck. When the ſound was liſtened to by a nice obſerver at the diſtance of more than two miles, no interval whatever could be obſerved. A ſimilar experiment was exhibited to M. Euler himſelf, by means of a curious muſical inſtrument (if it can be ſo called) uſed at St Peterſburgh, and which may be heard at three or four miles diſtance. But the experiment with the bells is unexceptionable, as the two ſounds were produced in the very ſame inſtant. This connexion between the refrangibility in general and the velocity muſt be admitted, in its full extent, in every attempt to explain refraction by undulation; and Euler was forced by it to adopt a certain conſequence which made a neceſſary connection between the mean refraction and the diſperſion of heterogeneous rays. Confident of his analyſis, he gave a deaf ear to all that was told him of Mr Dollond's improvements on teleſcopes, and aſſerted, that they could not be ſuch as were related; for an increaſe of mean refraction muſt always be accompanied with a *determined* increaſe of diſperſion. Newton had ſaid the ſame thing, being miſled by a limited view of his own principles; but the diſperſion aſſigned by him was different from that aſſigned by Euler. The diſpute between Euler and Dollond was confined to the deciſion of this queſtion only; and when ſome glaſſes made by a German chemiſt at St Peterſburgh convinced Euler that his determination was erroneous, he had not the candour to give up the principle which had forced him to this determination of the diſperſion, but immediately introduced a new theory of the achromatic teleſcopes of Dollond; a theory which took the artiſts out of the track marked out by mathematicians, and in which they had made conſiderable advances, and led them into another path, propoſing *maxims* of conſtruction hitherto untried, and inconſiſtent with real improvements which they had already made. The leading principle in this theory is to arrange the different ultimate images of a point which ariſe either from the errors of a ſpherical figure or different refrangibility, in a ſtraight line paſſing through the centre of the eye. The theory itſelf is ſpecious; and it requires great mathematical ſkill to accompliſh this point, and hardly leſs to decide on the propriety of the conſtruction which it recommends. It is therefore but little known. But that it is a falſe theory, is evident from one ſimple conſideration. In the moſt indiſtinct viſion ariſing from the worſt conſtruction, this rectilineal arrangement of the images obtains completely in that pencil which is ſituated in the axis, and yet the viſion is indiſtinct. But, what is to our preſent purpoſe, this new theory is purely mathematical, ſuiting any obſerved diſperſive power, and has no connexion with the phyſical theory of undulations, or indeed with any mechanical principles whatever. But, by admitting any diſperſive power, whatever may be the mean refraction, all the phyſical doctrines in his *Nova Theoria Lucis et Colorum* are overlooked, and therefore never once mentioned, although the effects of Mr Zeiher's glaſs are taken notice of as inconſiſtent with that mechanical propoſition.

137
and miſleads artiſts.

Cauſe of Refraction.

propoſition of Newton's which occaſioned the whole diſpute between Euler and Dollond.

They are indeed inconſiſtent with the univerſality of that propoſition. Newton advances it in his Optics merely as a mathematical propoſition highly probable, but ſays that it will be corrected *if he ſhall find it* falſe. The ground on which he *ſeems* (for he does not expreſsly ſay ſo) to reſt its probability is a limited view of his own principle, the action of bodies on light. He (not knowing any cauſe to the contrary) ſuppoſed that the action of all bodies was ſimilar on the different kinds of light, that is, that the ſpecific velocities of the differently coloured rays had a determined proportion to each other. This was gratuitous; and it might have been doubted by him who had obſerved the analogy between the chemical actions of bodies by elective attractions and repulſions, and the ſimilar actions on light. Not only have different menſtrua unequal actions on their ſolids, but the order of their affinities is alſo different. In like manner, we might expect not only that ſome bodies would attract light in general more than others, but alſo might differ in the proportion of their actions on the different kinds of light, and this ſo much, that ſome might even attract the red more than the violet. The late diſcoveries in chemiſtry ſhow us ſome very diſtinct proofs, that light is not exempted from the laws of chemical action, and that it is ſuſceptible of chemical combination. The changes produced by the ſun's light on vegetable colours, ſhows the neceſſity of illumination to produce the green fecula; and the aromatic oils of plants, the irritability of their leaves by the action of light, the curious effects of it on the mineral acids, on mangeneſe, and the calces of biſmuth and lead, and the imbibition and ſubſequent emiſſion of it by phoſphoreſcent bodies, are ſtrong proofs of its chemical affinities, and are quite inexplicable on the theory of undulations.

All theſe conſiderations taken together, had they been known to Sir Iſaac Newton, would have made him expect differences quite anomalous in the diſperſive powers of different tranſparent bodies; at the ſame time that they would have afforded to his ſagacious mind the ſtrongeſt arguments for the actual emiſſion of light from the luminous body.

Having in this manner eſtabliſhed the obſerved law of refraction on mechanical principles, ſhowing it to be a neceſſary conſequence of the known action of bodies on light, we proceed to trace its mathematical conſequences through the various caſes in which it may be exhibited to our obſervation. Theſe conſtitute that part of the mathematical branch of optical ſcience which is called *dioptrics*.

138 The variation of the intenſity of attractions and repulſions unknown.

We are quite unacquainted with the law of action of bodies on light, that is, with the variation of the intenſity of the attractions and repulſions exerted at different diſtances. All that we can ſay is, that from the experiments and obſervations of Grimaldi, Newton, and others, light is deflected towards a body or is attracted by it, at ſome diſtances, and repelled at others, and this with a variable intenſity. The action may be extremely different, both in extent and force, in different bodies, and change by a very different law with the ſame change of diſtance. But, amidſt all this variety, there is a certain ſimilarity ariſing from the joint action of many particles, which ſhould be noticed, becauſe it tends both to explain the ſimilarity obſerved in the refractions of light, and alſo its connexion with the phenomena of reflection.

auſe of fr ction.

The law of variation in the action of many particles different from that of one; bu may be known if it be known. Plate CCCLIV.

The law of variation in the joint action of many particles adjoining to the ſurface of a refracting medium, is extremely different from that of a ſingle particle; but when this laſt is known, the other may be found out. We ſhall illuſtrate this matter by a very ſimple caſe. Let DE (fig. 9.) be the ſurface of a medium, and let us ſuppoſe that the action of a particle of the medium on a particle of light extends to the diſtance EA, and that it is proportional to the ordinates ED, F*f*, G*g*, H*h*, &c. of the line A*h*C*gf*D; that is, that the action of the particle E of the medium on a particle of light in F, is to its action on a particle in H as F*f* to H*h*, and that it is attracted at F but repelled at H, as expreſſed by the ſituation of the ordinates with reſpect to the abſciſſa. In the line AE produced to B, make EB, Eχ, Eκ, Eγ, Eφ, &c. reſpectively equal to EA, EH, EC, EG, EF, &c.

It is evident that a particle of the medium at B will exert no action on the particle of light in E, and that the particles of the medium in κ γ φ E, will exert on it actions proportional to H*h*, G*g*, F*f*, ED. Therefore, ſuppoſing the matter of the medium continuous, the whole action exerted by the row of particles EB will be repreſented by the area A*h*CDE; and the action of the particles between B and φ will be repreſented by the area A*h*C*f*F, and that of the particles between E and φ by the area F*f*DE.

Now let the particle of light be in F, and take F*o*=AE. It is no leſs evident that the particle of light in F will be acted on by the particles in E*o* alone, and that it will be acted on in the ſame manner as a particle in E is acted on by the particles in φB. Therefore the action of the whole row of particles EB on a particle in F will be repreſented by the area A*h*C*f*F. And thus the action on a particle of light in any point of AE will be repreſented by the area which lies beyond it.

But let us ſuppoſe the particles of light to be within the medium, as at φ, and make φ*d*=AE. It is again evident that it is acted on by the particles of the medium between φ and *d* with a force repreſented by the area A*h*CDE, and in the oppoſite direction by the particles in Eφ with a force repreſented by the area F*f* DE. This balances an equal quantity of action, and there remains an action expreſſed by the area A*h*C*f*F. Therefore, if an equal and ſimilar line to A*h*CDE be deſcribed on the abſciſſa EB, the action of the medium on a particle of light in φ will be repreſented by the area φ*fκh*B, lying beyond it.

If we now draw a line AKLMRNPB, whoſe ordinates CK, FQ, φR, &c. are as the areas of the other curve, eſtimated from A and B; theſe ordinates will repreſent the whole forces which are exerted by the particles in EB, on a particle of light moving from A to B. This curve will cut the axis in points L, N ſuch, that the ordinates drawn through them intercept areas of the firſt curve, which are equal on each ſide of the axis; and in theſe points the particle of light ſuſtains no action from the medium. Theſe points are very

Cauſe of Refraction.

very different from the ſimilar points of the curve expreſſing the action of a ſingle particle. Theſe laſt are in the very places where the light ſuſtains the greateſt repulſive action of the whole row of particles. In the ſame manner may a curve be conſtructed, whoſe ordinates expreſs the united action of the whole medium.

From theſe obſervations we learn in general, that a particle of light within the ſpace of action is acted on with equal forces, and in the ſame direction, when at equal diſtances on each ſide of the ſurface of the medium.

Of the focal diſtance of rays refracted by paſſing out of one medium into another of different denſity and through a plane ſurface.

Lemma. The indefinitely ſmall variation of the angle of incidence is to the ſimultaneous variation of the angle of refraction as the tangent of incidence is to the tangent of refraction; or, the cotemporaneous variations of the angles of incidence and refraction are proportional to the tangents of theſe angles.

Plate CCCLIV. 140 Laws of refraction in plane ſurfaces.

Let RVF, rVf (fig. 10.) be the progreſs of the rays refracted at V (the angle rVR being conſidered in its naſcent or evaneſcent ſtate), and VC perpendicular to the refracting ſurface VA. From C draw CD, CB, perpendicular to the incident and refracted rays RV, VF, cutting rV, Vf in δ and β, and let Cd, Cb be perpendicular to rV, Vf.

Becauſe the ſines of incidence and refraction are in a conſtant ratio, their ſimultaneous variations are in the ſame conſtant ratio. Now the angle RVr is to the angle FVf in the ratio of $\frac{B\beta}{BV}$ to $\frac{D\delta}{DV}$; that is, of $\frac{BC}{BV}$ to $\frac{DC}{DV}$: that is, of $\frac{\text{ſin. incid.}}{\text{coſ. incid.}}$ to $\frac{\text{ſin. refr.}}{\text{coſ. refr.}}$; that is, of *tan. incid.* to *tan. refr.*

Corollary. The difference of theſe variations is to the greateſt or leaſt of them as the difference of the tangents to the greateſt or leaſt tangent.

PROBLEM.

Plate CCCLV.

Let two rays RV, RP diverge from, or converge to, a point R (figs. 1, 2, 3, 4.), and paſs through the plane ſurface PV ſeparating two refracting mediums AB, of which let B be the moſt refracting, and let RV be perpendicular to the ſurface. It is required to determine the point of diſperſion or convergence, F, of the refracted rays VD, PE.

Make VR to VG as the ſine of refraction to the ſine of incidence, and draw GIK parallel to the ſurface, cutting the incident ray in I. About the centre P, with the radius PI, deſcribe an arch of a circle IF, cutting VR in F; draw PE tending from or towards F. We ſay PE is the refracted ray, and F the point of diſperſion or convergence of the rays RV, RP, or the conjugate focus to R.

For ſince GI and PV are parallel and PF equal to PI, we have PF : PR=PI : PR,=VG : VR,=ſin. incid. : ſin. refr. But PF : PR=ſin. PRV : ſin. PFV, and RRV is equal to the angle of incidence at P; therefore PFV is the correſponding angle of refraction, FPE is the refracted ray, and F the conjugate focus to R.

Cauſe of Refraction.

Corol. 1. If diverging or converging rays fall on the ſurface of a more refracting medium, they will diverge or converge leſs after refraction, F being farther from the ſurface than R. The contrary muſt happen when the diverging or converging rays fall on the ſurface of a leſs refracting medium, becauſe, in this caſe, F is nearer to the ſurface than R.

Corol. 2. Let Rp be another ray, more oblique than RP, the refracting point p being farther from V, and let fpe be the refracted ray, determined by the ſame conſtruction. Becauſe the arches FI, fi, are perpendicular to their radii, it is evident that they will converge to ſome point within the angle RIK, and therefore will not croſs each other between F and I: therefore Rf will be greater than RF, as RF is greater than RG, for ſimilar reaſons. Hence it follows, that all the rays which tended from or towards R, and were incident on the whole of VPp, will not diverge from or converge to F, but will be diffuſed over the line GFf. This diffuſion is called aberration from the focus, and is ſo much greater as the rays are more oblique. No rays flowing from or towards R will have point of concourſe with RV nearer to R than F is: But if the obliquity be inconſiderable, ſo that the ratio of RP to FP does not differ ſenſibly from that of RV to FV, the point of concourſe will not be ſenſibly removed from G. G is therefore uſually called the *conjugate focus* to R. It is the conjugate focus of an indefinitely ſlender pencil of rays falling perpendicularly on the ſurface. The conjugate focus of an oblique pencil, or even of two oblique rays, whoſe diſperſion on the ſurface is conſiderable, is of more difficult inveſtigation. See *Graveſande's Natural Philoſophy* for a very neat and elementary determination (E).

In a work of this kind, it is enough to have pointed out, in an eaſy and familiar manner, the nature of optical aberration. But as this is the chief cauſe of the imperfection of optical inſtruments, and as the only method of removing this imperfection is to diminiſh this aberration, or correct it by a ſubſequent aberration in the oppoſite direction, we ſhall here give a fundamental and very ſimple propoſition, which will (with obvious alterations) apply to all important caſes. This is the determination of the focus of an infinitely ſlender pencil of oblique rays RP, Rp.

"Retaining the former conſtructions for the ray PF, (fig. 1.) ſuppoſe the other ray Rp infinitely near to RP. Draw PS perpendicular to PV, and Rr perpendicular to RP, and make Pr : PS=VR : VF. On Pr deſcribe the ſemicircle rRP, and on PS the ſemicircle $S\varphi P$, cutting the refracted ray PF in φ, draw pr, pS, $p\varphi$." It follows

---

(E) We refer to Graveſande, becauſe we conſider it as of importance to make ſuch a work as ours ſerve as a general index to ſcience and literature. At the ſame time we take the liberty to obſerve, that the focus in queſtion is virtually determined by the conſtruction which we have given: for the points P, F of the line PF are determined, and therefore its poſition is alſo determined. The ſame is true of the poſition of pf, and therefore the interſection φ of the two lines is likewiſe determined.

Refraction by Spherical Surfaces.

follows from the lemma, that if φ be the focus of refracted rays, the variation $P\varphi p$ of the angle of refraction is to the correſponding variation PRp of the angle of incidence as the tangent of the angle of refraction VFP to the tangent of the angle of incidence VRP. Now Pp may be conſidered as coinciding with the arch of the ſemicircles. Therefore the angles PRp, Prp are equal, as alſo the angles $P\varphi p$, PSp. But PSp is to Prp as Pr to PS; that is, as VR to VF; that is, as the cotangent of the angle of incidence to the cotangent of the angle of refraction; that is, as the tangent of the angle of refraction to the tangent of the angle of incidence. Therefore the point φ is the focus.

Of Refraction by Spherical Surfaces.

General Problem.

To find the focus of refracted rays, the focus of incident rays being given.

Plate CCCLV.

Let $PV\pi$ (figs. 5, 6, 7, 8, 9, 10, 11, 12, 13, 14,) be a ſpherical ſurface whoſe centre is C, and let the incident light diverge from or converge to R.

Solution. Draw the ray RC through the centre, cutting the ſurface in the point V, which we ſhall denominate the *vertex*, while RC is called the *axis*. This ray paſſes on without refraction, becauſe it coincides with the perpendicular to the ſurface. Let RP be another incident ray, which is refracted at P, draw the radius PC. In RP make RE to RP as the ſine of incidence m to the ſine of refraction n; and about the centre R, with the diſtance RE, deſcribe the circle EK, cutting PC in K; draw RK and PF parallel to it, cutting the axis in F. PF is the refracted ray, and F is the focus.

141 The focus of rays refracted by ſpherical ſurfaces aſcertained.

For the triangles PCF, KCR are ſimilar, and the angles at P and K are equal. Alſo RK is equal to RE, and RPD is the angle of incidence. Now $m:n=RK:RP$, $=$ſin. DPR : ſin. RKP, $=$ſin. DPR : ſin. CPF. Therefore CPF is the angle of refraction correſponding to the angle of incidence RPD, and PF is the refracted ray, and F the focus. Q. E. D.

Cor. 1. $CK:CP=CR:CF$, and $CF=\frac{CP\times CR}{CK}$; Now $CP\times CR$ is a conſtant quantity; and therefore CF is reciprocally as CK, which evidently varies with a variation of the arch VP. Hence it follows, that all the rays flowing from R are not collected as the conjugate focus F. The ultimate ſituation of the point F, as the point P gradually approaches to, and at laſt coincides with, V, is called *the conjugate focus of central rays*, and the diſtance between this focus and the focus of a lateral ray is called *the aberration* of that ray, ariſing from the ſpherical figure.

There are, however, two ſituations of the point R ſuch, that all the rays which flow from it are made to diverge from one point. One of thoſe is C (fig. 5.), becauſe they all paſs through without refraction, and therefore ſtill diverge from C; the other is when rays in the rare medium with a convex ſurface flow from a point R, ſo ſituated beyond the centre that CV is to CR as the ſine of incidence in the rare medium is to the ſine of refraction in the denſer, or when rays in the rare medium fall on the convex ſurface of the denſer, converging to F, ſo ſituated that $CF:CV=m:n$. In this caſe they will all be diſperſed from F, ſo ſituated that $CV:CF=n:m$, $=CR:CV$ for ſine RPC : ſine RKC$=n:m$, $=CR:CP$, $=$ſine RPC : ſine PRC. Therefore the angle PRC is equal to RKC, or to FPC (by conſtruction of the problem), and the angle C is common to the triangles PRC, FPC; they are therefore ſimilar, and the angles PRC, FPC are equal, and $n:m=CP:CF$, $=CK:CR$, $=CR:CP$; therefore $CP:CK=CP^2:CR^2$: but CP and CR are conſtant quantities, and therefore CK is a conſtant quantity, and (by the corollary) CF is a conſtant quantity, and all the rays flowing from R are diſperſed from F by refraction. In like manner rays converging to F will by refraction converge to R. This was firſt obſerved by Huygens.

2. If the incident ray R′P (fig. 5.) is parallel to the axis RC, we have PO to CO as the ſine of incidence to the ſine of refraction. For the triangles R′PK′ PCO are ſimilar, and $PO:CO=R'K':R'P$, $=m:n$,

3. In this caſe, too, we have the focal diſtance of central parallel rays reckoned from the vertex $=\frac{m}{m-n}\times VC$. For ſince PO is ultimately VO, we have $m:n=VO:CO$, and $m-n:m=VO-CO:VO$, $=VC:VO$, and $VO=\frac{m}{m-n}\times VC$. This is called the principal focal diſtance, or focal diſtance of parallel rays. Alſo CO, the principal focal diſtance reckoned from the centre, $=\frac{n}{m-n}\times VC$.

N. B. When m is leſs that n, $m-n$ is a negative quantity.—Alſo obſerve, that in applying ſymbols to this computation of the focal diſtances, thoſe lines are to be accounted poſitive which lie from their beginnings, that is, from the vertex, or the centre, or the radiant point, in the direction of the incident rays. Thus when rays diverge from R on the convex ſurface of a medium, VR is accounted negative and VC poſitive. If the light paſſes out of air into glaſs, m is greater than n; but if it paſſes out of glaſs into air, m is leſs than n. If, therefore, parallel rays fall on the convex ſurface of glaſs out of air, in which caſe $m:n=3:2$ very nearly, we have for the principal focal diſtance $\frac{3}{3-2}VC$, or $+3VC$. But if it paſs out of glaſs into the convex ſurface of air, we have $VO=\frac{2}{2-3}VC$, or $-2VC$; that is, the focus O will be in the ſame ſide of the ſurface with the incident light. In like manner, we ſhall have for theſe two caſes $CO=+2VC$ and $-3VC$.

4. By conſtruction we have $RK:RP=m:n$

by ſimilarity of triangles $PF:RK=CF:CR$

therefore $PF:PR=mCF:nCR$

and $mPR\times CF=nCR\times PF$

therefore $mPR:nCR=PF:CF$

and $mPR-nCR:mPR=PF-CF:PF$

ultimately $mVR-nCR:mVR=VC:VF$

This is a very general optical theorem, and affords an eaſy method for computing the focal diſtance of refracted rays.

For this purpoſe let VR, the diſtance of the radiant point,

point, be expreſſed by the ſymbol r, the diſtance of the focus of refracted rays by the ſymbol f, and the radius of the ſpherical ſurface by a; we have

$$mr - n\overline{r - a} : mr = a : f, \text{ and}$$

$$f = -$$

$$mr - n\,\overline{r - a} \qquad m - nr + nd$$

In its application due attention muſt be paid to the qualities of r and a, whether they be poſitive or negative, according to the conditions of laſt corollary.

Plate CCCLV.

5. If Q (fig. 8.) be the focus of parallel rays coming from the oppoſite ſide, we ſhall have RQ : QC=RV : VF. For draw Cq parallel to PF, cutting RP in q; then Rq : qC=RP : PF. Now q is the focus of the parallel rays FP, Cq. And when the point P ultimately coincides with the point V, q muſt coincide with Q, and we have RQ : QC=RV : VF.

This is the moſt general optical theorem, and is equally applicable to lenſes, or even to a combination of them, as to ſimple ſurfaces. It is alſo applicable to reflections, with this difference, that Q is to be aſſumed the focus of parallel rays coming the *ſame* way with the incident rays. It affords us the moſt compendious methods of computing ſymbolically and arithmetically the focal diſtances in all caſes.

6. We have alſo Rq : RP=RV : RF, and ultimately for central rays RQ : RV=RV : RF, and RF=$\frac{RV^2}{RQ}$. This propoſition is true in lenſes and mirrors, but not in ſingle refracting ſurfaces.

7. Alſo Rq : RC=RP : RF, and ultimately RQ : RV=RC : RF, and RF=$\frac{RV \times RC}{RQ}$. *N. B.* Theſe four points Q, V, C, F, either lie all one way from R, or two of them forward and two backward.

8. Alſo, making O the principal focus of rays coming the ſame way, we have Rq : qC=Co : oF, and ultimately RQ : Qc=cO : OF, and OF=$\frac{QC \times CO,}{RQ}$ and therefore reciprocally proportional to RQ, becauſe QC×co is a conſtant quantity.

Theſe corollaries or theorems give us a variety of methods for finding the focus of refracted rays, or the other points related to them; and each formula contains four points, of which any three being given the fourth may be found. Perhaps the laſt is the moſt ſimple, as the quantity $oc+c$Q is always negative, becauſe o and Q are on different ſides.

9. From this conſtruction we may alſo derive a very eaſy and expeditious method of drawing many refracted rays. Draw through the centre C (fig. 15. 16.) a line to the point of incidence P, and a line CA parallel to the incident ray RP. Take VO to VC as the ſine of incidence to the ſine of refraction, and about A, with the radius VO, deſcribe an arch of a circle cutting PC produced in B. Join AB: and PF parallel to AB is the refracted ray. When the incident light is parallel to RC, the point A coincides with V, and a circle deſcribed round V with the diſtance VO will cut the lines PC, pC, &c. in the points Bb. The demonſtration is evident.

Having thus determined the focal diſtance of refracted rays, it will be proper to point out a little more particularly its relation to its conjugate focus of incident rays. We ſhall conſider the four caſes of light incident on the convex or concave ſurface of a denſer or a rarer medium.

Refraction by Spherical Surfaces.

1. Let light moving in air fall on the convex ſurface of glaſs (fig. 5. to fig. 14.). Let us ſuppoſe it tending to a point beyond the glaſs infinitely diſtant. It will be collected to its principal focus o beyond the vertex V. Now let the incident light converge a little, ſo that R is at a great diſtance beyond the ſurface. The focus of refracted rays F will be a little within O or nearer to V. As the incident rays are made to converge more and more, the point R comes nearer to V, and the point F alſo approaches it, but with a much ſlower motion, being always ſituated between O and C till it is overtaken by R at the centre C, when the incident light is perpendicular to the ſurface in every point, and therefore ſuffers no refraction. As R has overtaken F at C, it now paſſes it, and is again overtaken by it at V. Now the point R is on the ſide from which the light comes, that is, the rays diverge from R. After refraction they will diverge from F a little without R; and as R recedes farther from V, F recedes ſtill farther, and with an accelerated motion, till, when R comes to Q, F has gone to an infinite diſtance, or the refracted rays are parallel. When R ſtill recedes, F now appears on the other ſide, or beyond V; and as R recedes back to an infinite diſtance, F has come to O: and this completes the ſeries of variations, the motion of F during the whole changes of ſituation being in the ſame direction with the motion of R.

2. Let the light moving in air fall on the concave ſurface of glaſs; and let us begin with parallel incident rays, conceiving, as before, R to lie beyond the glaſs at an infinite diſtance. The refracted rays will move as if they came from the principal focus O, lying on that ſide of the glaſs from which the light comes. As the incident rays are made gradually more converging, and the point of convergence R comes toward the glaſs, the conjugate focus F moves backward from O; the refracted rays growing leſs and leſs diverging, till the point R comes to Q, the principal focus on the other ſide. The refracted rays are now parallel, or F has retreated to an infinite diſtance. The incident light converging ſtill more, or R coming between Q and V, F will appear on the other ſide, or beyond the ſurface, or within the glaſs, and will approach it with a retarded motion, and finally overtake R at the ſurface of the glaſs. Let R continue its motion backwards (for it has all the while been moving backwards, or in a direction contrary to that of the light); that is, let R now be a radiant point, moving backwards from the ſurface of the glaſs. F will at firſt be without it, but will be overtaken by it at the centre C, when the rays will ſuffer no refraction. R ſtill receding will get without F; and while R recedes to an infinite diſtance, F will recede to O, and the ſeries will be completed.

3. Let the light moving in glaſs fall on the convex ſurface of air; that is, let it come out of the concave ſurface of glaſs, and let the incident rays be parallel, or tending to R, infinitely diſtant: they will be diſperſed by refraction from the principal focus O within the glaſs. As they are made more converging, R comes nearer, and F retreats backward, till R comes

to Q, the principal focus without the glaſs; when F is now at an infinite diſtance within the glaſs, and the refracted rays are parallel. R ſtill coming nearer, F now appears before the glaſs, overtakes R at the centre C, and is again overtaken by it at V. R now becoming a radiant point within the glaſs, F follows it backwards, and arrives at O, when R has receded to an infinite diſtance, and the ſeries is completed.

4. Let the incident light, moving in glaſs, fall on the concave ſurface of air, or come out of the convex ſurface of glaſs. Let it tend to a point R at an infinite diſtance without the glaſs. The refracted rays will converge to O, the principal focus without the glaſs. As the incident light is made more converging, R comes towards the glaſs, while F, ſetting out from *v*, alſo approaches the glaſs, and R overtakes it at the ſurface V. R now becomes a radiant point within the glaſs, receding backwards from the ſurface. F recedes ſlower at firſt, but overtakes R at the centre C, and paſſes it with an accelerated motion to an infinite diſtance; while R retreats to Q, the principal focus within the glaſs. R ſtill retreating, F appears before the glaſs; and while R retreats to an infinite diſtance, F comes to V, and the ſeries is completed.

§ 2. *Of Glaſſes.*

142
Lenſes how many.

Glaſs for optical purpoſes may be ground into nine different ſhapes. Glaſſes cut into five of thoſe ſhapes are called *lenſes*, which together with their axes are deſcribed in Vol. VI. page 33. (See Dioptrics). The other four are,

Plate CCLVI.

1. A *plane glaſs*, which is flat on both ſides, and of equal thickneſs in all its parts, as EF, fig. 1.

2. A *flat plano-convex*, whoſe convex ſide is ground into ſeveral little flat ſurfaces, as A, fig. 2.

3. A *priſm*, which has three flat ſides, and when viewed endwiſe appears like an equilateral triangle, as B.

4. A *concavo-convex* glaſs, as C, which has hitherto received no name, and is ſeldom, if ever, made uſe of in optical inſtruments.

A ray of light G*h* (fig. 1.) falling perpendicularly on a plane glaſs EF, will paſs through the glaſs in the ſame direction *hi*, and go out of it into the air in the ſame ſtraight line *i* H.

A ray of light AB falling obliquely on a plane glaſs, will go out of the glaſs in the ſame direction, but not in the ſame ſtraight line; for in touching the glaſs, it will be refracted in the line BC; and in leaving the glaſs, it will be refracted in the line CD.

Fig. 3. to 6.

Lemma. There is a certain point E within every double convex or double concave lens, through which every ray that paſſes will have its incident and emergent parts QA, *aq* parallel to each other: but in a plano-convex or plano-concave lens, that point E is removed to the vertex of the concave or convex ſurface; and in a meniſcus, and in that other concavo-convex lens, it is removed a little way out of them, and lies next to the ſurface which has the greateſt curvature.

For let RE*r* be the axis of the lens joining the centres R, *r* of its ſurfaces A, *a*. Draw any two of their ſemidiameters RA, *ra* parallel to each other, and join the point, A, *a*, and the line A*a* will cut the axis in the point E above deſcribed. For the triangles REA, *r*E*a* being equiangular, RE will be to E*r* in the given ratio of the ſemidiameters RA, *ra*; and conſequently the point E is invariable in the ſame lens. Now ſuppoſing a ray to paſs both ways along the line A*a*, it being equally inclined to the perpendiculars to the ſurfaces, will be equally bent, and contrariwiſe in going out of the lens; ſo that its emergent parts AQ, *aq* will be parallel. Now any of theſe lenſes will become plano-convex or plano-concave, by conceiving one of the ſemidiameters RA, *ra* to become infinite, and conſequently to become parallel to the axis of the lens, and then the other ſemidiameter will coincide with the axis; and ſo the points A, E or *a*, E will coincide. Q. E. D.

Corol. Hence when a pencil of rays falls almoſt perpendicularly upon any lens, whoſe thickneſs is inconſiderable, the courſe of the ray which paſſes through E, above deſcribed, may be taken for a ſtraight line paſſing through the centre of the lens without ſenſible error in ſenſible things. For it is manifeſt from the length of A*a*, and from the quantity of the refractions at its extremities, that the perpendicular diſtance of AQ, *aq* when produced, will be diminiſhed both as the thickneſs of the lens and the obliquity of the ray is diminiſhed.

PROPOSITION I.

To find the focus of parallel rays falling almoſt perpendicularly upon any given lens.

Fig. 7. to 12.

143
The focus of parallel rays falling perpendicularly upon any lens.

Let E be the centre of the lens, and *r* the centres of its ſurfaces, R*r* its axis, *g*EG a line parallel to the incident rays upon the ſurface B, whoſe centre is R. Parallel to *g*E draw a ſemidiameter BR, in which produced let V be the focus of the rays after their firſt refraction at the ſurface B, and joining V*r* let it cut *g*E produced in G, and G will be the focus of the rays that emerge from the lens.

For ſince V is alſo the focus of the rays incident upon the ſecond ſurface A, the emergent rays muſt have their focus in ſome point of that ray which paſſes ſtraight through this ſurface; that is, in the line V*r*, drawn through its centre *r*: and ſince the whole courſe of another ray is reckoned a ſtraight line *g*EG ‡, its interſection G with V*r* determines the focus of them all. Q. E. D.

‡ Corol. from Lemma.

Corol. 1. When the incident rays are parallel to the axis *r*R, the focal diſtance EF is equal to EG. For let the incident rays that were parallel to *g*E be gradually more inclined to the axis till they become parallel to it; and their firſt and ſecond focuſes V and G will deſcribe circular arches VT and GF whoſe centres are R and E. For the line RV is invariable; being in proportion to RB in a given ratio of the leſſer of the ſines of incidence and refraction to their difference§; conſequently the line EG is alſo invariable, being in proportion to the given line RV in the given ratio of *r*E to *r*R, becauſe the triangles EG*r*, RV*r* are equiangular.

§ By a former Prop.

Corol. 2. The laſt proportion gives the following rule for finding the focal diſtance of any thin lens. As R*r*, the interval between the centres of the ſurfaces, is to *r*E, the ſemidiameter of the ſecond ſurface, ſo is RV or RT, the continuation of the firſt ſemidiameter to the firſt focus, to EG or EF the focal diſtance of the lens; which, according as the lens is thicker or thinner in the middle than at its edges, muſt lie on the ſame ſide as the emergent rays, or on the oppoſite ſide.

Corol. 3. Hence when rays fall parallel on both ſides of any lens, the focal diſtances EF, Ef are equal. For let rt be the continuation of the ſemidiameter Er to the firſt focus t of rays falling parallel upon the ſurface A; and the ſame rule that gave rR to rE as RT to EF, gives alſo rR to RE as rt to Ef. Whence Ef and EF are equal, becauſe the rectangles under rE, RT and alſo under RE, rt are equal. For rE is to rt and alſo RE to RT in the ſame given ratio.

Corol. 4. Hence in particular in a double convex or double concave lens made of glaſs, it is as the ſum of their ſemidiameters (or in a meniſcus as their difference) to either of them, ſo is double the other, to the focal diſtance of the glaſs. For the continuations RT, rt are ſeverally double their ſemidiameters: becauſe in glaſs ET is to TR and alſo Et to tr as 3 to 2.

Corol. 5. Hence if the ſemidiameters of the ſurfaces of the glaſs be equal, its focal diſtance is equal to one of them; and is equal to the focal diſtance of a plano-convex or plano-concave glaſs whoſe ſemidiameter is as ſhort again. For conſidering the plane ſurface as having an infinite ſemidiameter, the firſt ratio of the laſt mentioned proportion may be reckoned a ratio of equality.

PROPOSITION II.

144 The focus of emergent rays found.

The focus of incident rays upon a ſingle ſurface, ſphere, or lens, being given, it is required to find the focus of the emergent rays.

Plate CCCLVII. fig. 1. to 6.

Let any point Q be the focus of incident rays upon a ſpherical ſurface, lens, or ſphere, whoſe centre is E; and let other rays come parallel to the line QEq the contrary way to the given rays, and after refraction let them belong to a focus F; then taking Ef equal to EF in the lens or ſphere, but equal to FC in the ſingle ſurface, ſay as QF to FE ſo Ef to fq; and placing fq the contrary way from f to that of FQ from F, the point q will be the focus of the refracted rays, without ſenſible error; provided the point Q be not ſo remote from the axis, nor the ſurfaces ſo broad as to cauſe any of the rays to fall too obliquely upon them.

For with the centre E and ſemidiameters EF and Ef deſcribe two arches FG, fg cutting any ray $QAaq$ in G and g, and draw EG and Eg. Then ſuppoſing G to be a focus of incident rays (as GA), the emergent rays (as agq) will be parallel to GE†; and on the other hand ſuppoſing g another focus of incident rays (as ga), the emergent rays (as AGQ) will be parallel to gE. Therefore the triangles QGE, Egq are equiangular, and conſequently QG is to GE as Eg to gq; that is, when the ray $QAaq$ is the neareſt to QEq, QF is to FE as Ef to fg. Now when Q accedes to F and coincides with it, the emergent rays become parallel, that is, q recedes to an infinite diſtance; and conſequently when Q paſſes to the other ſide of F, the focus q will alſo paſs through an infinite ſpace from one ſide of f to the other ſide of it. Q. E. D.

† By Corol. from former Prop.

Corol. 1. In a ſphere or lens the focus q may be found by this rule: As QF to QE ſo QE to Qq, to be placed the ſame way from Q as QF lies from Q.—For let the incident and emergent ray QA, qa be produced till they meet in e; and the triangles QGE, Qeq being equiangular, we have QG to QE as Qe to Qq; and when the angles of theſe triangles are vaniſhing, the point e will coincide with E; becauſe in the ſphere the triangle Aea is equiangular at the baſe Aa, and conſequently Ae and ae will at laſt become ſemidiameters of the ſphere. In a lens the thickneſs Aa is inconſiderable.

The focus may alſo be found by this rule;—$QF : FE :: QE : Eq$, for $QG : GE :: QA : Aq$.—And then the rule formerly demonſtrated for ſingle ſurfaces holds good for the lenſes.

Corol. 2. In all caſes the diſtance fq varies reciprocally as FQ does; and they lie contrariwiſe from f and F; becauſe the rectangle or the ſquare under EF and Ef, the middle terms in the foregoing proportions, is invariable.

The principal focal diſtance of a lens may not only be found by collecting the rays coming from the ſun, conſidered as parallel, but alſo (by means of this propoſition) it may be found by the light of a candle or window. For, becauſe $Qq : qA :: QE : EG$, we have (when A coincides with E) $Qq : qE = QE : EF$; that is, the diſtance obſerved between the radiant object and its picture in the focus is to the diſtance of the lens from the focus as the diſtance of the lens from the radiant is to its principal focal diſtance. Multiply therefore the diſtances of the lens from the radiant and focus, and divide the product by their ſum.

Corol. 3. Convex lenſes of different ſhapes that have equal focal diſtances, when put into each others places, have equal powers upon any pencil of rays to refract them to the ſame focus. Becauſe the rules abovementioned depend only upon the focal diſtance of the lens, and not upon the proportion of the ſemidiameters of its ſurfaces.

Corol. 4. The rule that was given for a ſphere of an uniform denſity, will ſerve alſo for finding the focus of a pencil of rays refracted through any number of concentric ſurfaces, which intercede uniform mediums of any different denſities. For when rays come parallel to any line drawn through the common centre of theſe mediums, and are refracted through them all, the diſtance of their focus from that centre is invariable, as in an uniform ſphere.

Corol. 5. When the focuſes Q, q lie on the ſame ſide of the refracting ſurfaces, if the incident rays flow from Q, the refracted rays will alſo flow from q; and if the incident rays flow towards Q, the refracted will alſo flow towards q: and the contrary will happen when Q and q are on contrary ſides of the refracting ſurfaces. Becauſe the rays are continually going forwards.

From this propoſition we alſo derive an eaſy method of drawing the progreſs of rays through any number of lenſes ranged on a common axis.

Let A, B, C, (fig. 7.) be the lenſes, and RA a ray incident on the firſt of them. Let α, β, κ, be their foci for parallel rays coming in the oppoſite direction; draw the perpendicular $\alpha\, d$, cutting the incident ray in d, and draw $d\, a$ through the centre of the lens: AB parallel to $d\, a$ will be the ray refracted by the firſt lens. Through the focus of the ſecond lens draw the perpendicular $\beta\, e$, cutting AB in *e*; and draw *e b* through the centre of the ſecond lens. BD parallel to *b e* will be the next refracted ray. Through the focus *x* of the third lens draw the perpendicular *x f*, cutting BD in *f*, and draw *f c* through the centre of the third lens. CE parallel to *f c*, will be the refracted ray; and ſo on.

§ 3. *Of Viſion.*

Having deſcribed how the rays of light, flowing from objects, and paſſing through convex glaſſes, are collected into points, and form the images of the objects; it will be eaſy to underſtand how the rays are affected by paſſing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For the different humours of the eye, and particularly the cryſtalline humour, are to be conſidered as a convex glaſs; and the rays in paſſing through them to be affected in the ſame manner as in paſſing through a convex glaſs. A deſcription of the coats and humours, &c. has been given at large in ANATOMY; but for the reader's convenience in this place, we ſhall repeat in a few words as much of the deſcription as will be ſufficient for our preſent purpoſe.

Plate CCCLVII. fig. 8.

145 Deſcription of the eye.

The eye is nearly globular. It conſiſts of three coats and three humours. The part DHHG of the outer coat, is called the *ſclerotica*; the reſt, DEFG, the *cornea*. Next within this coat is that called the *choroides*, which ſerves as it were for a lining to the other, and joins with the iris, *m n*, *m n*. The iris is compoſed of two ſets of muſcular fibres; the one of a circular form, which contracts the hole in the middle called the *pupil*, when the light would otherwiſe be too ſtrong for the eye; and the other of radical fibres, tending everywhere from the circumference of the iris towards the middle of the pupil; which fibres, by their contraction, dilate and enlarge the pupil when the light is weak, in order to let in the more of its rays. The third coat is only a fine expanſion of the optic nerve L, which ſpreads like net work all over the inſide of the choroides, and is therefore called the *retina*; upon which are painted (as it were) the images of all viſible objects, by the rays of light which either flow or are reflected from them.

Under the cornea is a fine tranſparent fluid like water, which is therefore called the *aqueous humour*. It gives a protuberant figure to the cornea, fills the two cavities *m m* and *n n*, which communicate by the pupil P; and has the ſame limpidity, ſpecific gravity, and refractive power, as water. At the back of this lies the cryſtalline humour II, which is ſhaped like a double convex glaſs; and is a little more convex on the back than the fore part. It converges the rays, which paſs through it from every viſible object to its focus at the bottom of the eye. This humour is tranſparent like cryſtal, is much of the conſiſtence of hard jelly, and exceeds the ſpecific gravity of water in the proportion of 11 to 10. It is encloſed in a fine tranſparent membrane, from which proceed radial fibres *o o*, called the *ligamentum ciliare* all around its edge; and join to the circumference of the iris.

At the back of the cryſtalline, lies the vitreous humour KK, which is tranſparent like glaſs, and is largeſt of all in quantity, filling the whole orb of the eye, and giving it a globular ſhape. It is much of a conſiſtence with the white of an egg, and very little exceeds the ſpecific gravity and refractive power of water.

146 The objects on the retina of the eye are inverted.

As every point of an object ABC, (*ibid.*) ſends out rays in all directions, ſome rays, from every point on the ſide next the eye, will fall upon the cornea between E and F; and by paſſing on through the humours and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a diſtinct inverted picture *c b a*, of the object. Thus, the pencil of rays *q r s* that flows from the point A of the object, will be converged to the point *a* on the retina; thoſe from the point B will be converged to the point *b*; thoſe from the point C will be converged to the point *c*; and ſo of all the intermediate points: by which means the whole image *a b c* is formed, and the object made viſible. Although it muſt be owned, that the method by which this ſenſation is carried from the eye by the optic nerve to the common ſenſory in the brain, and there diſcerned, is above the reach of our comprehenſion.

But that viſion is effected in this manner, may be demonſtrated experimentally. Take a bullock's eye whilſt it is freſh; and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will ſee an inverted picture of the object upon the paper.

147 Why they are ſeen upright.

Since the image is inverted, many have wondered why the object appears upright. But we are to conſider, 1. That *inverted* is only a relative term: and, 2. That there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a diſtant proſpect are painted upon the retina, they are all right with reſpect to one another, as well as the parts of the proſpect itſelf; and we can only judge of an object's being inverted, when it is turned reverſe to its natural poſition with reſpect to other objects which we ſee and compare it with.—If we lay hold of an upright ſtick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Juſt ſo we find by experience, that upon directing our eyes towards a tall object, we cannot ſee its top by turning our eyes downward, nor its foot by turning our eyes upward; but muſt trace the object the ſame way by the eye to ſee it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one caſe, ſo it is alſo by the motion of the eye in the other.

In fig. 9. is exhibited the manner of ſeeing the ſame object ABC, by both the eyes D and E at once.

148 An object when viewed with both eyes does not appear double, becauſe the optic nerve is inſenſible of light.

When any part of the image *c b a* falls upon the optic nerve L, the correſponding part of the object becomes inviſible. On which account, nature has wiſely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the ſide next the noſe; ſo that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point *a* of the

image

Fig. 1.

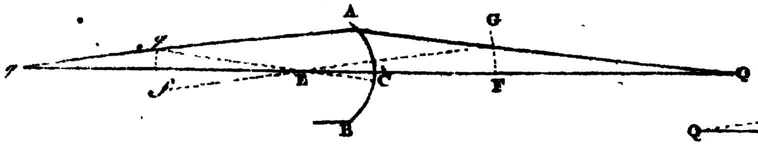

Fig. 2.

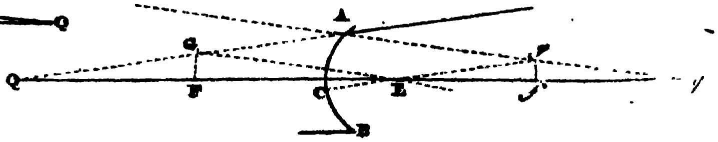

Fig. 3.

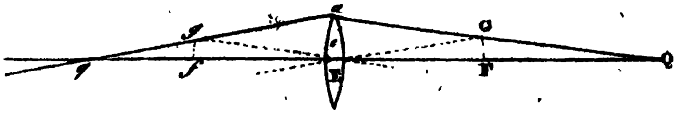

Fig. 4.

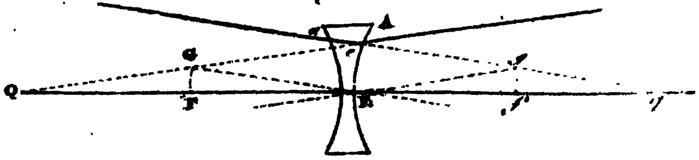

Fig. 5.

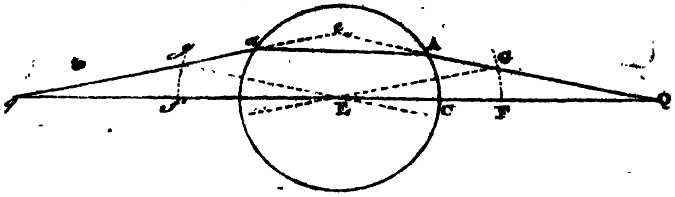

Fig. 6.

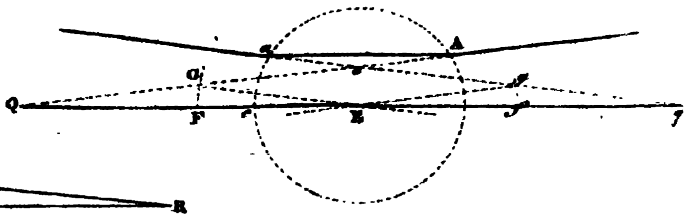

Fig. 7.

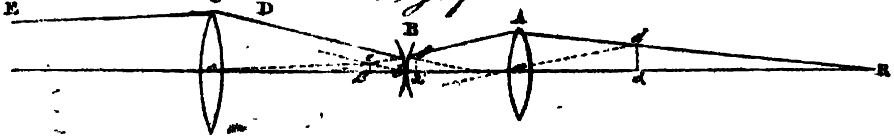

Fig. 8.

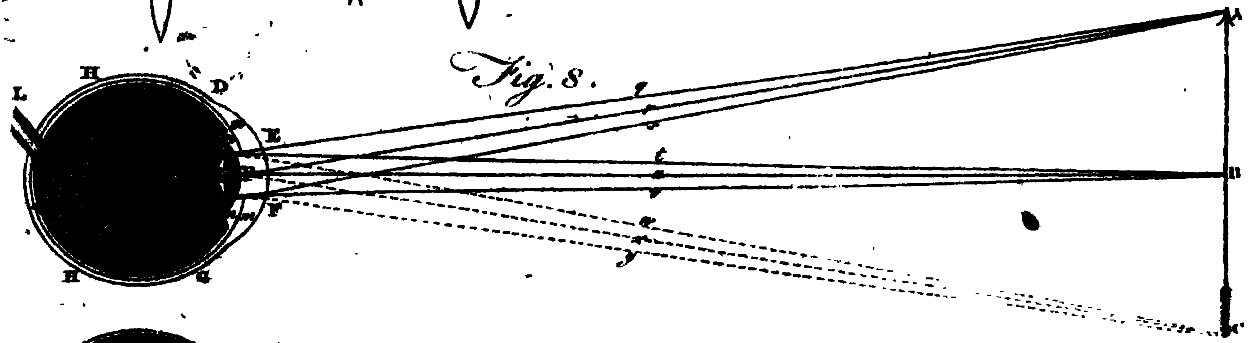

Fig. 9.

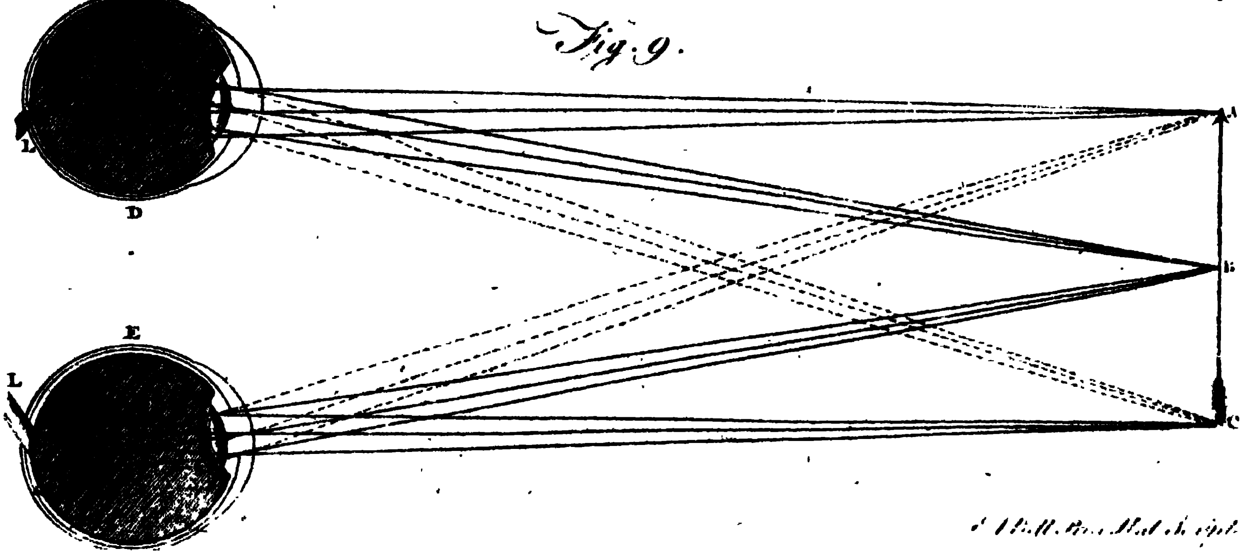

A. Bell Prin. Wal. Sculptor fecit.

image *c b a* falls upon the optic nerve of the eye D, but not of the eye E; and the point *c* falls upon the optic nerve of the eye E, but not of the eye D: and therefore, to both eyes taken together, the whole object ABC is viſible.

Plate CCCLVIII.

The nearer that any object is to the eye, the larger is the angle under which it is ſeen, and the magnitude under which it appears. Thus to the eye D, (fig. 1.) the object ABC is ſeen under the angle APC; and its image *c b a* is very large upon the retina: but to the eye E, at a double diſtance, the ſame object is ſeen under the angle A*p*C, which is equal only to half the angle APC, as is evident by the figure. The image *c b a* is likewiſe twice as large in the eye D, as the other image *c b a* is in the eye E. In both theſe repreſentations, a part of the image falls on the optic nerve, and the object in the correſponding part is inviſible.

As the ſenſe of ſeeing is allowed to be occaſioned by the impulſe of the rays from the viſible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the expanſion of the optic nerve all over the choroides; it ſhould ſeem ſurpriſing, that the part of the image which falls on the optic nerve ſhould render the like part of the object inviſible; eſpecially as that nerve is allowed to be the inſtrument by which the impulſe and image are conveyed to the common ſenſory in the brain.

149
Proved by experiment.

That the part of the image which falls upon the middle of the optic nerve is loſt, and conſequently the correſponding part of the object is rendered inviſible, is plain by experiment. For if a perſon fixes three patches, A, B, C, (fig. 2.) upon a white wall, at the height of the eye, and at the diſtance of about a foot from each other, and places himſelf before them, ſhutting the right eye, and directing the left towards the patch C, he will ſee the patches A and C, but the middle patch B will diſappear. Or, if he ſhuts his left eye, and directs the right towards A, he will ſee both A and C, but B will diſappear; and if he directs his eye towards B, he will ſee both B and A, but not C. For whatever patch is directly oppoſite to the optic nerve N, vaniſhes. This requires a little practice; after which he will find it eaſy to direct his eye ſo as to loſe the ſight of whichever patch he pleaſes.

150
Diſpute concerning the ſeat of viſion.

This experiment, firſt tried by M. Marriotte, occaſioned a new hypotheſis concerning the ſeat of viſion, which he ſuppoſed not to be in the retina, but in the choroides. An improvement was afterwards made upon it by M. Picard, who contrived that an object ſhould diſappear when both the eyes were kept open. He faſtened upon a wall a round white paper, an inch or two in diameter; and by the ſide of it he fixed two marks, one on the right hand, and the other on the left, each at about 2 feet diſtance from the paper, and ſomewhat higher. He then placed himſelf directly before the paper, at the diſtance of 9 or 10 feet, and putting the end of his finger over againſt both his eyes, ſo that the left hand mark might be hid from the right eye, and the right hand mark from the left eye. Remaining firm in this poſture, and looking ſteadily, with both eyes, on the end of his finger, the paper which was not at all covered by it would totally diſappear. This, he ſays, is the more ſurpriſing, becauſe, without this particular encounter of the optic nerves, where no viſion is made, the paper will appear double, as is the caſe when the finger is not rightly placed.

M. Marriotte obſerves, that this improvement on his experiment, by M. Picard, is ingenious, but difficult to execute, ſince the eyes muſt be conſiderably ſtrained in looking at any object ſo near to them as four inches; and propoſes another not leſs ſurpriſing, and more eaſy. Place, ſays, he, on a dark ground, two round pieces of white paper, at the ſame height, and three feet from one another; then place yourſelf oppoſite to them, at the diſtance of 12 or 13 feet, and hold your thumb before your eyes, at the diſtance of about eight inches, ſo that it may conceal from the right eye the paper that is to the left hand, and from the left eye the paper to the right hand. Then, if you look at your thumb ſteadily with both eyes, you will loſe ſight of both the papers; the eyes being ſo diſpoſed, that each of them receives the image of one of the papers upon the baſe of the optic nerve, while the other is intercepted by the thumb.

M. Le Cat purſued this curious experiment a little farther than M. Marriotte had done. In the place of the ſecond paper, he fixed a large white board, and obſerved, that at a proper diſtance he loſt ſight of a circular ſpace in the centre of it. He alſo obſerved the ſize of the paper which is thus concealed from the ſight, correſponding to ſeveral diſtances, which enabled him to aſcertain ſeveral circumſtances relating to this part of the ſtructure of the eye more exactly than had been done before.

The manner in which this curious experiment is now generally made, and which is both the eaſieſt with reſpect to the eye, and the moſt indiſputable with reſpect to the fact, is the following. Let three pieces of paper be faſtened upon the ſide of a room, about two feet aſunder; and let a perſon place himſelf oppoſite to the middle paper, and, beginning near to it, retire gradually backwards, all the while keeping one of his eyes ſhut, and the other turned obliquely towards that outſide paper which is towards the covered eye, and he will find a ſituation (which is generally at about five times the diſtance at which the papers are placed from one another), where the middle paper will entirely diſappear, while the two outermoſt continue plainly viſible; becauſe the rays which come from the middle paper will fall upon the retina where the optic nerve is inſerted.

It will not ſurpriſe any perſon, even thoſe who are the ſtrongeſt advocates for the retina being the place at which the pencils of rays are terminated, and conſequently the proper ſeat of viſion, that M. Marriotte was led by this remarkable obſervation to ſuſpect the contrary. He not only did ſo; but, in conſequence of attentively conſidering the ſubject, a variety of other arguments in favour of the choroides occurred to him, particularly his obſervation, that the retina is tranſparent, as well as the cryſtalline and other humours of the eye, which he thought could only enable it to tranſmit the rays farther; and he could not perſuade himſelf that any ſubſtance could be conſidered as being the termination of the pencils, and the proper ſeat of viſion, at which the rays are not ſtopped in their progreſs.

He was farther confirmed in his opinion of the ſmall degree of ſenſibility in the retina, and of the greater ſenſibility of the choroides, by obſerving that the pupil dilates itſelf in the ſhade, and contracts itſelf in a great light; which involuntary motion, he thought, was a clear proof that the fibres of the iris are extremely ſenſible to the action of light; and this part of the eye is only a continuation of the choroides. He alſo thought that the dark colour of the choroides was intended to make it more ſuſceptible of the impreſſion of light.

M. Pecquet, in anſwer to M. Marriotte's obſervation concerning the tranſparency of the retina, ſays, that it is very imperfectly ſo, reſembling only oiled paper, or the horn that is uſed for lanterns; and beſides, that its whiteneſs demonſtrates it to be ſufficiently opaque for ſtopping the rays of light, as much as is neceſſary for the purpoſe of viſion; whereas, if viſion be performed by means of thoſe rays which are tranſmitted through ſuch a ſubſtance as the retina, it muſt be very indiſtinct.

As to the blackneſs of the choroides, which M. Marriotte thought to be neceſſary for the purpoſe of viſion, M. Pecquet obſerves, that it is not the ſame in all eyes, and that there are very different ſhades of it among the individuals of mankind, as alſo among birds, and ſome other animals, whoſe choroides is generally black; and that in the eyes of lions, camels, bears, oxen, ſtags, ſheep, dogs, cats, and many other animals, that part of the choroides which is the moſt expoſed to light, very often exhibits colours as vivid as thoſe of mother-of-pearl, or of the iris (F). He admits that there is a defect of viſion at the inſertion of the optic nerve; but he thought that it was owing to the blood veſſels of the retina, the trunks of which are ſo large in that place as to obſtruct all viſion.

To M. Pecquet's objection, founded on the opacity of the retina, M. Marriotte obſerves, that there muſt be a great difference betwixt the ſtate of that ſubſtance in living and dead ſubjects; and as a further proof of the tranſparency of the retina, and the power of the choroides beyond it to reflect light, he ſays, that if a lighted candle be held near to a perſon's eyes, and a dog, at the diſtance of eight or ten ſteps, be made to look at him, he would ſee a bright light in the dog's eyes, which he thought to proceed from the reflection of the light of the candle from the choroides of the dog, ſince the ſame appearance cannot be produced in the eyes of men, or other animals, whoſe choroides is black.

To M. Pecquet's remark concerning the blood veſſels of the retina, M. Marriotte obſerves, that they are not large enough to prevent viſion in every part of the baſe of the nerve, ſince the diameter of each of the two veſſels occupies no more than $\frac{1}{8}$th part of it. Beſides, if this were the cauſe of this want of viſion, it would vaniſh gradually, and the ſpace to which it is confined would not be ſo exactly terminated as it appears to be.

We muſt add, that M. Pecquet alſo obſerved, that notwithſtanding the inſenſibility of the retina at the inſertion of the optic nerve when the light is only moderate; yet that luminous objects, ſuch as a bright candle placed at the diſtance of four or five paces, do not abſolutely diſappear, in the ſame circumſtances in which a white paper would; for that this ſtrong light may be perceived though the picture fall on the baſe of the nerve. "I cannot help ſuſpecting, however, (ſays Dr Prieſtley), that M. Pecquet did not make this obſervation with ſufficient care. A large candle makes no impreſſion on that part of my eye, though it is by no means able to bear a ſtrong light."

The common opinion was alſo favoured by the anatomical deſcription of ſeveral animals by the members of the French academy, and particularly their account of the ſea calf and porcupine; in both of which the optic nerve is inſerted in the very axis of the eye, exactly oppoſite to the pupil, which was thought to leave no room to doubt, but that in theſe animals the retina is perfectly ſenſible to the impreſſion of light at the inſertion of the nerve. But this obſervation may deſerve to be reconſidered.

M. De la Hire took part with M. Pecquet, arguing in favour of the retina from the analogy of the ſenſes, in all of which the nerves are the proper ſeat of ſenſation. This philoſopher, however, ſuppoſed that the choroides receives the impreſſions of images, in order to tranſmit them to the retina.

M. Perrault alſo took the part of M. Pecquet againſt M. Marriotte, and in M. Perrault's works we have ſeveral letters that paſſed between theſe two gentlemen upon this ſubject.

This diſpute about the immediate inſtrument of viſion was revived upon the occaſion of an odd experiment of M. Mery, recorded in the Memoirs of the French Academy for 1704. He plunged a cat in water, and expoſing her eye to the ſtrong light of the ſun, obſerved that the pupil was not at all contracted by it; from which he concluded, that the contraction of the iris is not produced by the action of the light, but by ſome other circumſtance. For he contended that the eye receives more light in this ſituation than in the open air. At the ſame time he thought he obſerved that the retina of the cat's eye was tranſparent, and that he could ſee the opaque choroides beyond it: from which he concludes, that the choroides is the ſubſtance intended to receive the rays of light, and to be the chief inſtrument of viſion. But M. De la Hire replies to this argument of M. Mery, in a memoir for the year 1709, p. 119; in which he endeavours to ſhow that fewer rays enter the eye under water, and that in thoſe circumſtances it is not ſo liable to be affected by them. Beſides, it is obvious to be remarked, that the cat muſt be in great terror in this ſituation; and being an animal that has a very great voluntary power over the muſcles of the iris, and being now extremely attentive to every thing about her, ſhe might keep her eye open notwithſtanding

---

(F) M. Muſſchenbroek ſays, that in many animals, as the lion, camel, bear, ox, ſtag, ſheep, dog, cat, and many birds, the choroides is not black, but blue, green, yellow, or ſome other colour. *Introductio*, Vol. II. p. 748.

ſtanding the action of the light upon it, and though it might be very painful to her. We are informed, that when a cat is placed in a window through which the ſun is ſhining, and conſequently her iris nearly cloſed, if ſhe hear a ruſtling, like that which is made by a mouſe, on the outſide of the window, ſhe will immediately open her eyes to their greateſt extent, without in the leaſt turning her face from the light.

M. Le Cat took part with M. Marriotte in this controverſy, it being peculiarly agreeable to his general hypotheſis, viz. that the pia mater, of which the choroides is a production, and not the nerves themſelves, is the proper inſtrument of ſenſation. He thought that the change which takes place in the eyes of old people (the choroides growing leſs black with age) favoured his hypotheſis, as they do not ſee with that diſtinctneſs with which young perſons do. M. Le Cat ſuppoſed that the retina anſwers a purpoſe ſimilar to that of the ſcarf-ſkin, covering the papillæ pyramidales, which are the immediate organs of feeling, or that of the porous membrane which covers the glandulous papillæ of the tongue. The retina, he ſays, receives the impreſſion of light, moderates it, and prepares it for its proper organ, but is not itſelf ſenſible of it.

It muſt be obſerved, that M. Le Cat had diſcovered that the pia mater, after cloſely embracing and conſtringing the optic nerve at its entrance into the eye, divides into two branches, one of which cloſely lines the cornea, and at length is loſt in it, while the ſecond branch makes what is called the *choroides*, or *uvea*. He alſo ſhowed that the ſclerotica is an expanſion of the dura mater; and he ſent diſſections of the eye to the Royal Academy of Sciences in 1739, to prove theſe aſſertions, and ſeveral others which he had advanced in his *Traité de Sens*, that were contrary to the opinions of the celebrated Winſlow.

To theſe arguments in favour of the choroides, alleged by thoſe gentlemen among whom the ſubject was firſt diſcuſſed, Dr Prieſtley in his hiſtory adds the following that had eſcaped their notice, but which were ſuggeſted to him by his friend Mr Michell.

In order that viſion be diſtinct, the pencils of rays which iſſue from the ſeveral points of any object, muſt be collected either accurately, or at leaſt very nearly, to correſponding points in the eye, which can only be done upon ſome uniform ſurface. But the retina being of a conſiderable thickneſs, and the whole of it being uniformly nervous, and at leaſt nearly, if not perfectly, tranſparent, preſents no particular ſurface; ſo that, in whatever part of it the pencils be ſuppoſed to have their foci, the rays belonging to them will be ſeparated from one another, either before or after they arrive there, and conſequently viſion would be confuſed.

If we ſuppoſe the ſeat of viſion to be at the nearer ſurface of the retina, and the images of objects to be formed by direct rays, a conſiderable degree of confuſion could not but ariſe from the light reflected by the choroides, in thoſe animals in which it is white, or coloured. On the other hand, it would be impoſſible that viſion ſhould be performed at this place by light reflected from the choroides, becauſe in many animals it is perfectly black, and reflects no light at all; and yet ſuch animals ſee even more diſtinctly than others. And we cannot but ſuppoſe that, in whatever manner viſion is effected, it is the ſame in the eyes of all animals.

If the ſeat of viſion be at the farther ſurface of the retina, and it be performed by direct rays, a white choroides could be of no uſe; and if it were by reflected rays, a black one could not anſwer the purpoſe.

It is likewiſe an argument in favour of the choroides being the organ of viſion, that it is a ſubſtance which receives a more diſtinct impreſſion from the rays of light than any other membrane in any part of the animal ſyſtem, excepting (and perhaps not excepting) that white cuticle which lies under the ſcales of fiſhes; whereas the retina is a ſubſtance on which the light makes an exceedingly faint impreſſion, and perhaps no impreſſion at all; ſince light, in paſſing out of one tranſparent medium into another immediately contiguous to it, ſuffers no refraction or reflection, nor are any of the rays abſorbed, unleſs there is ſome difference in the refracting power of the two media, which probably is not the caſe between the retina and the vitreous humour, which is in contact with it. And wherever the light is not affected by the medium it falls upon, we can hardly ſuppoſe the medium to receive any impreſſion from the light, the action being probably always mutual and reciprocal.

Beſides, the retina is ſo ſituated, as to be expoſed to many rays beſides thoſe which terminate in it, and which, therefore, cannot be ſubſervient to viſion, if it be performed there. Now this is not the caſe with the choroides, which is in no ſhape tranſparent, and has no reflecting ſubſtance beyond it.

It is, moreover, peculiarly favourable to the hypotheſis of the ſeat of viſion being in the choroides, that we can then ſee a ſufficient reaſon for the diverſity of its colour in different animals, according as they are circumſtanced with reſpect to viſion. In all terreſtrial animals, which have occaſion to make uſe of their eyes by night, the choroides is either of a bright white, or of ſome very vivid colour, which reflects the light very ſtrongly. On this account viſion may be performed with leſs light, but it cannot be with great diſtinctneſs, the reflection of the rays doubling their effect, ſince it muſt extend over ſome ſpace, all reflection being made at a diſtance from the reflecting body. Beſides, the choroides in brutes is not in general perfectly white, but a little inclined to blue; and is therefore, probably, better adapted to ſee by the fainter coloured light, which chiefly prevails in the night; and we would add, is on the ſame account more liable to be ſtrongly impreſſed by the colours to which they are chiefly expoſed.

On the other hand, the choroides of birds in general, eſpecially eagles, hawks, and other birds of prey, is black; by which means they are able to ſee with the greateſt diſtinctneſs, but only in bright day light. The owl, however, ſeeking her food by night, has the choroides white, like that of a cat. Laſtly, In the eyes of man, which are adapted to various uſes, the choroides is neither ſo black as that of birds, nor ſo white as that of thoſe animals who make the greateſt uſe of their eyes in the night.

As to a third hypotheſis, which is in effect that of M. De la Hire, which makes both the retina and the choroides equally neceſſary to viſion, and ſuppoſes it to be performed by the impreſſion of light on the choroides, communicated to the retina; Mr Michell obſerves, that the perceptions can hardly be ſuppoſed to be ſo acute, when the nerves, which are the chief inſtruments of ſenſation, do not receive the impreſſions immediately, but only after they have been communicated to another ſubſtance. Beſides, it muſt be more natural to ſuppoſe, that, when the principal impreſſion is made upon the choroides, it is communicated to the brain by its own proper nerves, which are abundantly ſufficient for the purpoſe.

151
Dimenſions of the ſpot in the eye where there is no viſion.

Plate CCCLVIII

The dimenſions and preciſe form of the ſpot in the eye in which there is no viſion, were more accurately calculated by Daniel Bernouilli, in the following manner. He placed a piece of money O (fig. 3.) upon the floor; and then ſhutting one of his eyes, and making a pendulum to ſwing, ſo that the extremity of it might be nearly in the line AO, he obſerved at what place C it began to be inviſible, and where it again emerged into view at A. Raiſing the pendulum higher and lower, he found other points, as H, N, P, G, B, at which it began to be inviſible; and others, as M, L, E, A, at which it began to be viſible again; and drawing a curve through them, he found that it was elliptical; and, with reſpect to his own eye, the dimenſions of it were as follow; OC was 23, AC 10, BD 3, DH 13, and EG 14; ſo that the centre being at F, the greater axis was to the leſs as 8 to 7.

From theſe *data* the plane on which the figure was drawn being obliquely ſituated with reſpect to the eye, he found, that the place in the eye that correſponded to it was a circle, the diameter of which was a ſeventh part of the diameter of the eye, the centre of it being 27 parts of the diameter from the point oppoſite to the pupil, a little above the middle. He concludes with obſerving, that, in order that this ſpace in which there is no viſion may be as ſmall as poſſible, it is neceſſary that the nerve ſhould enter the eye perpendicularly, and that both this end, and alſo its entering the eye at a diſtance from its axis, are gained by the particular manner in which the two optic nerves unite and become ſeparate again, by croſſing one another.

In favour of one of the obſervations of Mr Michell, concerning the uſe of the choroides in viſion, Dr Prieſtley obſerves, that Aquapendente mentions the caſe of a perſon at Piſa, who could ſee very well in the night, but very little or none at all in the day time. This is alſo ſaid to be the caſe with thoſe white people among the blacks of Africa, and the inhabitants of the iſthmus of America, who, from this circumſtance, are called *moon-eyed*, Our author thinks it probable that their choroides is not of a dark colour, as it is in others of the human ſpecies; but white or light-coloured, as in thoſe animals which have moſt occaſion for their eyes in the night. See ALBINOS.

The following conſiderations in favour of the retina being the proper ſeat of viſion, are worthy of remark.

152
Arguments for the retina's being the ſeat of viſion.

Dr Porterfield obſerves, that the reaſon why there is no viſion at the entrance of the optic nerve into the eye, may be, that it wants that ſoftneſs and delicacy which it has when it is expanded upon the choroides; and that, in thoſe animals in which that nerve is inſerted in the axis of the eye, it is obſerved to be equally delicate, and therefore probably equally ſenſible, in that place as in any other part of the retina. In general, the nerves, when conſtringed by their coats, have but little ſenſibility in compariſon of what they are endued with when they are diveſted of them, and unfolded in a ſoft and pulpy ſubſtance.

Haller obſerves, that the choroides cannot be the univerſal inſtrument of viſion, becauſe that ſometimes in men and birds, but eſpecially in fiſhes, it is covered internally with a black mucus, through which the rays cannot penetrate. This writer ſpeaks of a fibrous membrane in the retina diſtinct from its pulpy ſubſtance. On theſe fibres, he conjectures, that the images of objects are painted.

M. De la Hire's argument in favour of the retina, from the analogy of the ſenſes, is much ſtrengthened by conſidering that the retina is a large nervous apparatus, immediately expoſed to the impreſſion of light; whereas the choroides receives but a ſlender ſupply of nerves, in common with the ſclerotica, the conjunctiva, and the eyelids, and that its nerves are much leſs expoſed to the light than the naked fibres of the optic nerve. Indeed, from anatomical conſiderations, one might imagine that any other part of the body was as ſenſible of the impreſſion of light as the choroides.

That the optic nerve is of principal uſe in viſion, is farther probable from ſeveral phenomena attending ſome of the diſeaſes in which the ſight is affected. When an amauroſis has affected one eye only, the optic nerve of that eye has been found manifeſtly altered from its ſound ſtate. Dr Prieſtley was preſent when Mr Hey examined the brain of a young girl, who had been blind of one eye, and ſaw that the optic nerve belonging to it was conſiderably ſmaller than the other; and he informed him, that upon cutting into it, he found it to be much harder, and cineritious. Morgagni, indeed, mentions two caſes, in one of which he found the optic nerves ſmaller than uſual, and of a cineritious colour, when, upon inquiry, he was informed that the perſon had not been blind, though there might have been ſome defect in the ſight of one of the eyes. In the other caſe, only one of the optic nerves was affected in that manner, and the eye itſelf was in other reſpects very perfect. Here, alſo, he was expreſsly told, that the perſon was not blind of that eye; but it appears that he himſelf had not been acquainted with the perſons whom he diſſected; and there have been many caſes of perſons being blind of one eye, without knowing it themſelves, for a a conſiderable time.

Moreover, as the optic nerve is ſolely ſpent in forming the retina, ſo no function of the eye not immediately ſubſervient to viſion, is affected by an amauroſis. On the contrary, thoſe nerves which go to the choroides are found to retain, in this diſeaſe, their natural influence. The iris will contract in a recent gutta ſerena of one eye, if the other remains ſound, and is ſuddenly expoſed to a ſtrong light. The ſclerotis, conjunctiva, and eyelids, which receive their nerves from the ſame branches as the choroides, retain their ſenſibility in this diſorder.

The manner in which perſons recover from an amauroſis, favours the ſuppoſition of the ſeat of viſion being in the retina: ſince thoſe parts which are the moſt diſtant from the inſertion of the nerve recover their ſenſibility the ſooneſt, being in thoſe places the moſt pulpy and ſofteſt; whereas there is no reaſon to think that there is any difference in this reſpect in the different parts of the choroides. Mr Hey has been repeatedly informed, by perſons labouring under an imperfect amauroſis, or gutta ſerena, that they could not, when looking at any object with one eye, ſee it ſo diſtinctly when it was placed directly oppoſite to the pupil, as when it was ſituated ſomewhat obliquely. And thoſe perſons whom he had known to recover from a perfect amauroſis, firſt diſcovered the objects whoſe images fell upon that part of the retina which is at the greateſt diſtance from the optic nerve.

We ſhall conclude theſe remarks with obſerving, that if the retina be as tranſparent as it is generally repreſented to be, ſo that the termination of the pencils muſt neceſſarily be either upon the choroides, or ſome other opaque ſubſtance interpoſed between it and the retina, the action and reaction occaſioned by the rays of light being at the common ſurface of this body and the retina, both theſe mediums (ſuppoſing them to be equally ſenſible to the impreſſion of light) may be equally affected; but the retina, being naturally much more ſenſible to this kind of impreſſion, may be the only inſtrument by which the ſenſation is conveyed to the brain, though the choroides, or the black ſubſtance with which it is ſometimes lined, may alſo be abſolutely neceſſary for the purpoſe of viſion. Indeed when the reflection of the light is made at the common boundary of any two mediums, it is with no propriety that this effect is aſcribed to one of them rather than the other; and the ſtrongeſt reflections are often made back into the denſeſt mediums, when they have been contiguous to the rareſt, or even to a vacuum. This is not far from the hypotheſis of M. de la Hire, and will completely account for the entire defect of viſion at the inſertion of the optic nerve.

153 Of bright and obſcure viſion. Viſion is diſtinguiſhed into *bright* and *obſcure*, *diſtinct* and *confuſed*.—It is ſaid to be *bright*, when a ſufficient number of rays enter the pupil at the ſame time; *obſcure*, when too few. It is *diſtinct* when each pencil of rays is collected into a focus exactly upon the retina; *confuſed*, when they meet before they come at it, or when they would paſs it before they meet; for, in either of theſe laſt caſes, the rays flowing from different parts of the object will fall upon the ſame part of the retina, which muſt neceſſarily render the image confuſed and indiſtinct.—Now, that objects may appear with a due brightneſs, whether more or fewer rays proceed from them, we have a power of contracting or dilating the pupil, by means of the muſcular fibres of the iris, in order to take in more or fewer rays as occaſion requires. But this power has its limits. In ſome animals it is much greater than in others; particularly in ſuch as are obliged to ſeek their food by night as well as by day, as in cats, &c.

154 Of diſtinct viſion at different diſtances. That the rays may be collected into points exactly upon the retina, that is, that objects may appear *diſtinct*, whether they be nearer or farther off, *i, e.* whether the rays proceeding from them diverge more or leſs, we have a power of contracting or relaxing the *ligamenta ciliaria*, and thereby altering the form of the cryſtalline humour, and with it the focal diſtance of the rays. Thus when the object we view is far off, and the rays fall upon the pupil with a very ſmall degree of divergency, we contract the *ligamenta ciliaria*, which, being concave towards the vitreous humour, do thereby compreſs it more than otherwiſe they would do: by this means it is made to preſs harder upon the backſide of the cryſtalline humour, which is thereby rendered flatter; and thus the rays proceed farther before they meet in a focus, than otherwiſe they would have done. Add to this, that we dilate the pupils of our eyes (unleſs in caſes where the light is ſo ſtrong that it offends the eye), and thereby admit rays into them that are more diverging than thoſe which would otherwiſe enter. And, when the rays come from an object that is very near, and therefore diverge too much to be collected into their reſpective foci upon the retina, by relaxing the *ligamenta ciliaria*, we give the cryſtalline a more convex form, by which means the rays are made to ſuffer a proportionably greater degree of refraction in paſſing through it. Some philoſophers are of opinion that we do this by a power of altering the form of the eye; and others, by removing the cryſtalline forwards or backwards as occaſion requires: But neither of theſe opinions is probable; for the coats of the eye are too hard, in ſome animals, for the firſt; and, as to moving the cryſtalline out of its place, the cavities of the eye ſeem to be too well filled with the other humours to admit of ſuch removal.

Beſides this, in the caſe above-mentioned, by contracting the pupils of our eyes, we exclude the more diverging rays, and admit only ſuch as are more eaſily refracted into their reſpective foci (G). But viſion is not diſtinct at all diſtances, for our power of contracting and relaxing the *ligamenta ciliaria* is alſo circumſcribed within certain limits.

155 Of ſhort-ſighted and long-ſighted people. In thoſe eyes where the tunica cornea is very protuberant and convex, the rays of light ſuffer a very conſiderable refraction at their entrance into the aqueous humour, and are therefore collected into a focus before they fall upon the retina, unleſs the object be placed very near, ſo that the rays which enter the eye may have a conſiderable degree of divergency. People that have ſuch eyes are ſaid to be *purblind*. Now, the nearer an object is to the eye, the greater is the image of it therein, as explained above: theſe people, therefore can ſee much ſmaller objects than others, as ſeeing much nearer ones with the ſame diſtinctneſs; and their ſight continues good longer than that of other people, becauſe the tunica cornea of their eyes, as they grow old, becomes plainer, for want of that redundancy of humours with which they were filled before. On the contrary, old men having the cornea of their eyes too flat for want of a ſufficient quantity of the aqueous humour to fill them out, if the rays diverge

---

(G) Accordingly it is obſerved, that if we make a ſmall hole with the point of a needle through a piece of paper, and apply that hole cloſe to the eye, making uſe of it, as it were, inſtead of a pupil, we ſhall be able to ſee an object diſtinctly through it, though the object be placed within half an inch of the eye

Of Viſion.

too much before they enter the eye, they cannot be brought to a focus before they reach the retina: on which account thoſe people cannot ſee diſtinctly, unleſs the object be ſituated at a greater diſtance from the eye than is required for thoſe whoſe eyes are of a due form. The latter require the aſſiſtance of convex glaſſes to make them ſee objects diſtinctly; the former of concave ones. For if either the cornea *a b c* (fig. 4.), or cryſtalline humour *e*, or both of them, be too flat, as in the eye A, their focus will not be on the retina as at A, where it ought to be, in order to render viſion diſtinct; but beyond the eye, as at *f*. This is remedied by placing a convex glaſs *g h* before the eye, which makes the rays converge ſooner, and imprints the image duly on the retina at *d*. Again, If either the cornea, or cryſtalline humour, or both of them, be too convex, as in the eye B, the rays that enter it from the object C will be converged to a focus in the vitreous humour, as at *f*; and by diverging from thence to the retina, will form a very confuſed image thereon; and ſo of courſe, the obſerver will have as confuſed a view of the object as if his eye had been too flat. This inconvenience is remedied by placing a concave glaſs *g h* before the eye; which glaſs, by cauſing the rays to diverge between it and the eye, lengthens the focal diſtance ſo, that if the glaſs be properly choſen, the rays will unite at the retina, and form a diſtinct image of the object upon it.

Plate CCCLVIII.

156 Of the leaſt angle of viſion.

Such eyes as are of a due convexity, cannot ſee any object diſtinctly at leſs diſtance than ſix inches; and there are numberleſs objects too ſmall to be ſeen at that diſtance, becauſe they cannot appear under any ſenſible angle.—Concerning the leaſt angle under which any object is viſible, there was a debate between Dr Hooke and Hevelius. The former aſſerted that no object could well be ſeen if it ſubtended an angle leſs than one minute; and, if the object be round as a black circular ſpot upon a white ground, or a white circle upon a black ground, it follows, from an experiment made by Dr Smith, that this is near the truth; and from thence he calculates, that the diameter of the picture of ſuch leaſt viſible point upon the retina is the 8000th part of an inch; which he therefore calls a *ſenſible point of the retina*. On the other hand, Mr Courtivron concluded from his experiments, that the ſmalleſt angle of viſion was 40 ſeconds. According to Dr Jurin, there are caſes in which a much ſmaller angle than one minute can be diſcerned by the eye; and in order to throw light upon the ſubject, he obſerves, that in order to our perceiving the impreſſion made by any object upon our ſenſes, it muſt either be of a certain degree of force, or of a certain degree of magnitude. For this reaſon, a ſtar, which appears only as a lucid point through a teleſcope ſubtending not ſo much as an angle of one ſecond, is viſible to the eye; though a white or black ſpot of 25 or 30 ſeconds, is not to be perceived.

157 Lines can be ſeen under ſmaller angles than ſpots, and why.

Alſo a line of the ſame breadth with the circular ſpot will be viſible at ſuch a diſtance as the ſpot is not to be perceived at; becauſe the quantity of impreſſion from the line is much greater than from the ſpot; and a longer line is viſible at a greater diſtance than a ſhorter one of the ſame breadth. He found by experience, that a ſilver wire could be ſeen when it ſubtended an angle of three ſeconds and a half; and that a ſilk thread could be ſeen when it ſubtended an angle of two ſeconds and an half.

This greater viſibility of a line than of a ſpot ſeems to ariſe only from the greater quantity of the impreſſion; but without the limits of perfect viſion, our author obſerves, that another cauſe concurs, whereby the difference of viſibility between the ſpot and the line is rendered much more conſiderable. For the impreſſion upon the retina made by the line is then not only much greater, but alſo much ſtronger, than that of the ſpot; becauſe the faint image, or penumbra, of any one point of the line, when the hole is placed beyond the limits of diſtinct viſion, will fall within the faint image of the next point, and thereby much increaſe the light that comes from it.

In ſome caſes our author found the cauſe of indiſtinct viſion to be the unſteadineſs of the eye; as our being able to ſee a ſingle black line upon a white ground, or a ſingle white line upon a black ground, and not a white line between two black ones on a white ground. In viewing either of the former objects, if the eye be imperceptibly moved, all the effect will be, that the object will be painted upon a different part of the retina; but wherever it is painted, there will be but one picture, ſingle and uncompounded with any other. But in viewing the other, if the eye fluctuate ever ſo little, the image of one or other of the black lines will be ſo ſhifted to that part of the retina which was before poſſeſſed by the white line; and this muſt occaſion ſuch a dazzle in the eye, that the white line cannot be diſtinctly perceived, and diſtinguiſhed from the black lines; which, by a continual fluctuation, will alternately occupy the ſpace of the white line, whence muſt ariſe an appearance of one broad dark line, without any manifeſt ſeparation.

By trying this experiment with two pins of known diameters, ſet in a window againſt the ſky light, with a ſpace between them equal in breadth to one of the pins, he found that the diſtance between the pins could hardly be diſtinguiſhed when it ſubtended an angle of leſs than 40 ſeconds, though one of the pins alone could be diſtinguiſhed when it ſubtended a much leſs angle. But though a ſpace between two pins cannot be diſtinguiſhed by the eye when it ſubtends an angle leſs than 40 ſeconds, it would be a miſtake to think that the eye muſt neceſſarily commit an error of 40 ſeconds in eſtimating the diſtance between two pins when they are much farther from one another. For if the ſpace between them ſubtend an angle of one minute, and each of the pins ſubtend an angle of four ſeconds which is greater than the leaſt angle the eye can diſtinguiſh, it is manifeſt that the eye may judge of the place of each pin within two ſeconds at the moſt; and conſequently the error committed in taking the angle between them cannot at the moſt exceed four ſeconds, provided the inſtrument be ſufficiently exact. And yet, ſays he, upon the like miſtake was founded the principal objection of Dr Hooke againſt the accuracy of the celeſtial obſervations of Hevelius.

A black ſpot upon a white ground, or white ſpot upon a black ground, he ſays can hardly be perceived by the generality of eyes when it ſubtends a leſs angle than one minute. And if two black ſpots be made upon white paper, with a ſpace between them equal in breadth to one of their diameters, that ſpace is not to be diſtinguiſhed, even within the limits of perfect viſion, under ſo ſmall an angle as a ſingle ſpot of the ſame ſize can be diſtinguiſhed. To ſee the two ſpots diſtinctly, therefore, the breadth of the ſpace between them muſt ſubtend an angle of more than a minute. It would be very difficult, he ſays, to make this experiment accurately, within the limits of perfect viſion; becauſe the objects muſt be extremely ſmall: but by a rude trial, made with ſquare bits of white paper, placed upon a black ground, he judged, that the leaſt angle under which the interval of two objects could be perceived, was at leaſt a fourth part greater than the leaſt angle under which a ſingle object can be perceived. So that an eye which cannot perceive a ſingle object under a ſmaller angle than one minute, will not perceive the interval between two ſuch objects under a leſs angle than 75 ſeconds.

Without the limits of perfect viſion, the diſtance at which a ſingle object ceaſes to be perceivable will be much greater in proportion than the diſtance at which a ſpace of equal breadth between two ſuch objects ceaſes to be perceivable. For, without theſe limits, the image of each of the objects will be attended with a penumbra, and the penumbra of the two near objects will take up part of the ſpace between them, and thereby render it leſs perceivable; but the penumbra will add to the breadth of the ſingle object, and will thereby make it more perceivable, unleſs its image be very faint. Upon the ſame principles he likewiſe accounts for the radiation of the ſtars, whereby the light ſeems to project from them different ways at the ſame time.

Mr Mayer made many experiments in order to aſcertain the ſmalleſt angle of viſion in a variety of reſpects. He began with obſerving at what diſtance a black ſpot was viſible on white paper; and found, that when it could barely be diſtinguiſhed, it ſubtended an angle of about 34 ſeconds. When black lines were diſpoſed with intervals broader than themſelves, they were diſtinguiſhed at a greater diſtance than they could be when the objects and the intervals were of an equal breadth. In all theſe caſes it made no difference whether the objects were placed in the ſhade or in the ſtrong light of the ſun; but when the degrees of light were ſmall, their differences had a conſiderable effect, though by no means in proportion to the differences of the light. For if an object was illuminated to ſuch a degree as to be juſt viſible at the diſtance of nine feet, it would be viſible at the diſtance of four feet, though the light was diminiſhed above 160 times. It appeared in the courſe of theſe experiments, that common day light is, at a medium, equal to that of 25 candles placed at the diſtance of one foot from the object.

158
Of ſingle viſion with two eyes.

As an image of every viſible object is painted on the retina of each of our eyes, it thence becomes a natural queſtion, Why we do not ſee every thing double? It was the opinion of Sir Iſaac Newton and others, that objects appear ſingle becauſe the two optic nerves unite before they reach the brain. But Dr Porterfield ſhows, from the obſervation of ſeveral anatomiſts, that the optic nerves do not mix, or confound their ſubſtance, being only united by a cloſe cohesion; and objects have appeared ſingle where the optic nerves were found to be disjoined.

159
Solutions of this difficulty by Dr Briggs.

Dr Briggs ſuppoſed that ſingle viſion was owing to the equal tenſion of the correſponding parts of the optic nerves, whereby they vibrated in a ſynchronous manner. But, beſides ſeveral improbable circumſtances in this account, Dr Porterfield ſhows that facts do by no means favour it.

160
Dr Porterfield.

To account for this phenomenon, this ingenious writer ſuppoſes, that by an original law in our natures, we imagine objects to be ſituated ſomewhere in a right line drawn from the picture of it upon the retina, through the centre of the pupil. Conſequently, the ſame object appearing to both eyes to be in the ſame place, the mind cannot diſtinguiſh it into two. In anſwer to an objection to this hypotheſis, from objects appearing double when one eye is diſtorted, he ſays the mind miſtakes the poſition of the eye, imagining that it had moved in a manner correſponding to the other, in which caſe the concluſion would have been juſt. In this he ſeems to have recourſe to the power of habit, though in words he diſclaims that hypotheſis.

This principle, however, has generally been thought to be ſufficient to account for this appearance. Originally, every object making two pictures, one in each eye, is imagined to be double; but by degrees, we find, that when two correſponding parts of the retina are impreſſed, the object is but one; but if thoſe correſponding parts be changed, by the diſtortion of one of the eyes, the object muſt again appear double as at the firſt. This ſeems to be verified by Mr Cheſelden; who informs us, that a gentleman, who from a blow on his head had one eye diſtorted, found every object to appear double; but by degrees the moſt familiar ones came to appear ſingle again, and in time all objects did ſo, without any amendment of the diſtortion. A caſe ſimilar to this is mentioned by Dr Smith.

161
Dr Reid, and

On the other hand, Dr Reid is of opinion, that the correſpondence of the centres of the two eyes, on which ſingle viſion depends, does not ariſe from cuſtom, but from ſome natural conſtitution of the eye and of the mind. He makes ſeveral juſt objections to the caſe of Mr Foſter, recited by Dr Smith and others; and thinks that the caſe of the young man couched by Cheſelden, who ſaw ſingly with both eyes immediately upon receiving his ſight, is nearly deciſive in proof of his ſuppoſition. He alſo found that three young gentlemen, whom he endeavoured to cure of ſquinting, ſaw objects ſingly, as ſoon as ever they were brought to direct the centres of both their eyes to the ſame object, though they had never been uſed to do ſo from their infancy; and he obſerves, that there are caſes, in which, notwithſtanding the fulleſt conviction of an object being ſingle, no practice of looking at it will ever make it appear ſo, as when it is ſeen through a multiplying glaſs.

To all theſe ſolutions of the difficulty reſpecting ſingle viſion by both eyes, objections have been lately made which ſeem inſurmountable. By experiments judiciouſly conceived and accurately conducted, Dr Wells has ſhown, that it is neither by cuſtom alone, nor by the original property of the eyes alone, that objects appear ſingle; and having demoliſhed the theories of others, he thus accounts for the phenomenon himſelf.

162 Dr Wells.

“The viſible place of an object being compoſed of its viſible diſtance and viſible direction, to ſhow how it may appear the ſame to both eyes, it will be neceſſary (ſays he *) to explain in what manner the diſtance and direction, which are perceived by one eye, may coincide with thoſe which are perceived by the other.” With reſpect to viſible diſtance, the author's opinion ſeems not to differ from that which we have ſtated elſewhere (ſee METAPHYSICS, N° 49, 50); and therefore we have to attend only to what he ſays of viſible direction.

When a ſmall object is ſo placed with reſpect to either eye, as to be ſeen more diſtinctly than in any other ſituation, our author ſays that it is then in the *optic axis*, or the axis of that eye. When the two optic axes are directed to a ſmall object not very diſtant, they may be conceived to form two ſides of a triangle, of which the baſe is the interval between the points of the corners where the axes enter the eyes. This baſe he called the *viſual baſe;* and a line drawn from the middle of it to the point of interſection of the optic axis he calls the *common aixs*. He then proceeds to ſhow, that objects *really ſituated* in the *optic* axis do not *appear* to be in that line, but in the *common axis*.

“Every perſon (ſays he) knows, that if an object be viewed through two ſmall holes, one applied to each eye, the two holes appear but as one. The theories thitherto invented afford two explanations of this fact. According to Aguilonius, Dechales, Dr Porterfield, and Dr Smith, the two holes, or rather their borders, will be ſeen in the ſame place as the object viewed through them, and will conſequently appear united, for the ſame reaſon that the object itſelf is ſeen ſingle. But whoever makes the experiment will diſtinctly perceive, that the united hole is much nearer to him than the object; not to mention, that any fallacy on this head might be corrected by the information from the ſenſe of touch, that the card or other ſubſtance in which the holes have been made is within an inch or leſs of our face. The other explanation is that furniſhed by the theory of Dr Reid. According to it, the centres of the retinas, which in this experiment receive the pictures of the holes, will, by an original property, repreſent but one. This theory, however, though it makes the two holes to appear one, does not determine where this one is to be ſeen. It cannot be ſeen in only one of the perpendiculars to the images upon the retinas, for no reaſon can be given why this law, of viſible direction, which Dr Reid thinks eſtabliſhed beyond diſpute, if it operates at all, ſhould not operate upon both eyes at the ſame time; and if it be ſeen by both eyes in ſuch lines, it muſt appear where thoſe lines croſs each other, that is, in the ſame place with the object viewed through the holes, which, as I have already mentioned, is contrary to experience. Nor is it ſeen in any direction, the conſequence of a law affecting both eyes conſidered as one organ, but ſuſpended when each eye is uſed ſeparately. For when the two holes appear one, if we pay attention to its ſituation, and then cloſe one eye, the truly ſingle hole will be ſeen by the eye remaining open in exactly the ſame direction as the apparently ſingle hole was by both eyes.

“Hitherto I have ſuppoſed the holes almoſt touching the face. But they have the ſame unity of appearance, in whatever parts of the optic axes they are placed; whether both be at the ſame diſtance from the eyes, or one be cloſe to the eye in the axis of which it is, and the other almoſt contiguous to the object ſeen through them. If a line, therefore, be drawn from the object to one of the eyes, it will repreſent all the real or tangible poſitions of the hole, which allow the object to be ſeen by that eye, and the whole of it will coincide with the optic axis. Let a ſimilar line be drawn to the other eye, and the two muſt appear but as one line; for if they do not, the two holes in the optic axes will not, at every diſtance, appear one, whereas experiments prove that they do. This united line will therefore repreſent the viſible direction of every object ſituated in either of the optic axes. But the end of it, which is toward the face, is ſeen by the right eye to the left, and by the left eye as much to the right. It muſt be ſeen then in the middle between the two, and conſequently in the common axis. And as its other extremity coincides with the point where the optic axes interſect each other, the whole of it muſt lie in the common axis. Hence the truth of the propoſition is evident, that objects ſituated in the optic axis, do not appear to be in that line, but in the common axis.”

He then proves by experiments, for which we muſt refer to his work, that objects ſituated in the common axis do not *appear* to be in that line, but in the axis of the eye by which they are not ſeen: that is, an object ſituated in the common axis appears to the right eye in the axis of the left, and *vice verſa*. His next propoſition, proved likewiſe by experiments, is, that “objects, ſituated in any line drawn through the mutual interſection of the optic axes to the viſual baſe, do not appear to be in that line, but in another, drawn through the ſame interſection, to a point in the viſual baſe diſtant half this baſe from the ſimilar extremity of the former line towards the left, if the objects be ſeen by the right eye, but towards the right if ſeen by the left eye.”

From theſe propoſitions he thus ſatisfactorily accounts for ſingle viſion by both eyes. “If the queſtion be concerning an object at the concourſe of the optic axes, it is ſeen ſingle, becauſe its two ſimilar appearances, in regard to ſize, ſhape, and colour, are ſeen by both eyes in one and the ſame direction, or if you will, in two directions, which coincide with each other through the whole of their extent. It therefore matters not whether the diſtance be truly or falſely eſtimated; whether the object be thought to touch our eyes, or to be infinitely remote. And hence we have a reaſon, which no other theory of viſible direction affords, why objects appeared ſingle to the young gentleman mentioned by Mr Cheſelden, immediately after his being couched, and before he could have learned to judge of diſtance by ſight.

“When two ſimilar objects are placed in the optic axes, one in each, at equal diſtances from the eyes, they will appear in the ſame place, and therefore one, for the ſame reaſon that a truly ſingle object, in the concourſe of the optic axes, is ſeen ſingle.

“To finiſh this part of my ſubject, it ſeems only neceſſary to determine, whether the dependence of viſible direction upon the actions of the muſcles of the eyes be eſtabliſhed by nature, or by cuſtom. But facts are here wanting. As far as they go, however, they ſerve to prove that it ariſes from an original principle of our conſtitution. For Mr Cheſelden's patient ſaw objects ſingle, and conſequently in the ſame directions with both eyes, immediately after he was couched; and perſons affected with ſquinting from their earlieſt infancy ſee objects in the ſame directions with the eye they have never been accuſtomed to employ, as they do with the other they have conſtantly uſed."

---

* Eſſay on ſingle Viſion, &c.

The author removes many difficulties, and obviates the objections to which his theory may ſeem moſt liable. The whole work deſerves to be attentively ſtudied by every optician; and we therefore recommend it to the peruſal of our readers.

163
Objects ſeen with both eyes appear brighter than when ſeen with only one.

We are indebted to Dr Jurin for the following curious experiments, to determine whether an object ſeen by both eyes appears brighter than when ſeen with one only.

He laid a ſlip of clean white paper directly before him on a table, and applying the ſide of a book cloſe to his right temple, ſo as that the book was advanced conſiderably more forward than his face, he held it in ſuch a manner, as to hide from his right eye that half of the paper which lay to his left hand, while the left half of the paper was ſeen by both eyes, without any impediment.

Then looking at the paper with both eyes, he obſerved it to be divided, from the top to the bottom, by a dark line, and the part which was ſeen with one eye only was manifeſtly darker than that which was ſeen with both eyes; and, applying the book to his left temple, he found, by the reſult of the experiment, that both his eyes were of equal goodneſs.

He then endeavoured to find to what degree this exceſs of brightneſs amounted; and comparing it with the appearance of an object illuminated partly by one candle and partly by two, he was ſurpriſed to find that an object ſeen with two eyes is by no means twice as luminous as when it is ſeen with one only; and after a number of trials, by which he made the proportion leſs and leſs continually, he found, that when one paper was illuminated by a candle placed at the diſtance of three feet, and another paper by the ſame candle at the ſame diſtance, and by another candle at the diſtance of 11 feet, the former ſeen by both eyes, and the latter with one eye only, appeared to be of equal whiteneſs; ſo that an object ſeen with both eyes appears brighter than when it is ſeen with one only by about a 13th part. But he acknowledges, that it is difficult to make this experiment exactly.

He then proceeded to inquire, whether an object ſeen with both eyes appears any thing larger than when ſeen with one only; but he concluded that it did not, except on account of ſome particular circumſtances, as in the caſe of the binocular teleſcope and the concave ſpeculum.

M. du Tour maintains, that the mind attends to no more than the image made in one eye at a time; and produces ſeveral curious experiments in favour of this hypotheſis, which had alſo been maintained by Kepler and almoſt all the firſt opticians. But, as M. Buffon obſerves, it is a ſufficient anſwer to this hypotheſis, how ingeniouſly ſoever it may be ſupported, that we ſee more diſtinctly with two eyes than with one; and that when a round object is near us, we plainly ſee more of the ſurface in one caſe than in the other. There are alſo other facts which clearly prove the contrary of what is maintained by M. du Tour.

With reſpect to ſingle viſion with two eyes, Dr Hartley obſerves, that it deſerves particular attention, that the optic nerves of men, and ſuch other animals as look the ſame way with both eyes, unite in the *cella turcica* in a ganglion, or little brain, as one may call it, peculiar to themſelves; and that the aſſociations between ſynchronous impreſſions on the two retinas muſt be made ſooner and cemented ſtronger on this account: alſo that they ought to have a much greater power over one another's images, than in any other part of the body. And thus an impreſſion made on the right eye alone, by a ſingle object, may propagate itſelf into the left, and there raiſe up an image almoſt equal in vividneſs to itſelf; and conſequently when we ſee with one eye only, we may, however, have pictures in both eyes.

A curious deception in viſion, ariſing from the uſe of both eyes, was obſerved and accounted for by Dr Smith. It is a common obſervation, he ſays, that objects ſeen with both eyes appear more vivid and ſtronger than they do to a ſingle eye; eſpecially when both of them are equally good. A perſon not ſhort ſighted may ſoon be convinced of this fact, by looking attentively at objects that are pretty remote, firſt with one eye, and then with both. This obſervation gave occaſion to the conſtruction of the binocular teleſcope, in the uſe of which the phenomenon is ſtill more ſtriking.

Beſides this, our author obſerves, that there is another phenomenon obſervable with this inſtrument, which is very remarkable. In the foci of the two teleſcopes there are two equal rings, as uſual, which terminate the pictures of the objects there formed, and conſequently the viſible area of the objects themſelves. Theſe equal rings, by reaſon of the equal eye-glaſſes, appear equal, and equally diſtant when ſeen ſeparately by each eye; but when they are ſeen with both eyes, they appear much larger, and more diſtant alſo; and the objects ſeen through them do alſo appear much larger, though circumſcribed by their united rings, in the ſame places as when they were ſeen ſeparately.

He obſerves that the phenomenon of the enlarged circle of the viſible area in the binocular teleſcope, may be ſeen very plainly in looking at diſtant objects through a pair of ſpectacles, removed from the eyes about four or five inches, and held ſteady at that diſtance. The two innermoſt of the four apparent rings, which hold the glaſſes, will then appear united in one larger and more diſtant ring than the two outermoſt, which will hardly be viſible unleſs the ſpectacles be farther removed.

A curious circumſtance relating to the effect of one eye upon the other, was noticed by M. Æpinus, who obſerved, that, when he was looking through a hole made in a plate of metal, about the 10th part of a line in diameter, with his left eye, both the hole itſelf appeared larger, and alſo the field of view ſeen through it was more extended, whenever he ſhut his right eye; and both theſe effects were more remarkable when that eye was covered with his hand. He found conſiderable difficulty in meaſuring this augmentation of the apparent diameter of the hole, and of the field of view; but at length he found, that, when the hole was half an inch, and the tablet which he viewed through it was three feet from his eye, if the diameter of the field when both his eyes were open was 1, it became 1½ when the other eye was ſhut, and nearly 2 when his hand was laid upon it.

164
When one eye is cloſed, the pupil of the other is enlarged.

Upon examining this pheuomenon, it preſently appeared to depend upon the enlargement of the pupil of one eye when the other is cloſed, the phyſical or anatomical cauſe of which he did not pretend to aſſign; but he obſerves, that it is wiſely appointed by divine Providence, in order that when one eye fails, the field of view in the other may be extended. That this effect ſhould be more ſenſible when the eye is covered with the hand, is owing, he obſerves, to the eyelids not being impervious to the light. But the enlargement of the pupil does not enlarge the field of view, except in looking through a hole, as in this particular caſe; and therefore perſons who are blind of one eye can derive no advantage from this circumſtance. Before we applaud the wiſdom of Providence in any part of the conſtitution of nature, we ſhould be very ſure that we do not miſtake concerning the effects of that conſtitution.

A great deal has been written by Gaſſendi, Le Clerc, Muſſchenbroek, and Du Tour, concerning the place to which we refer an object viewed by one or both eyes. But the moſt ſatisfactory account of this matter that we have met with, the reader will find in Dr Well's Eſſay above quoted, which will teach any perſon how to ſatisfy himſelf by experiment with reſpect to viſible poſition and viſible motion.

§ 4. *Of the Appearance of Objects ſeen through Media of different Forms.*

165
The various appearances of objects ſeen thro' media of different forms ſtated and inveſtigated.

For the more eaſy apprehenſion of what relates to this ſubject, we ſhall premiſe the five following particulars, which either have been already mentioned, or follow from what has been before laid down.

1. That as each point of an object, when viewed by the naked eye, appears in its proper place, and as that place is always to be found in the line in which the axis of a pencil of rays flowing from it enters the eye, or elſe in the line which Dr Wells calls the common axis; we from hence acquire a habit of judging the point to be ſituated in that line: and, becauſe the mind is unacquainted with what refractions the rays ſuffer before they enter the eye, therefore, in caſes where they are diverted from their natural courſe, by paſſing through any medium, it judges the point to be in that line produced back in which the axis of a pencil of rays flowing from it is ſituated the inſtant they enter the eye, and not in that it was in before refraction. We ſhall therefore, in what follows, ſuppoſe the apparent place of an object, when ſeen through a refracting medium, to be ſomewhere in that line produced back in which the axis of a pencil of rays flowing from it proceeds after they have paſſed through the medium.

2. That we are able to judge, though imperfectly, of the diſtance of an object by the degree of divergency, wherein the rays flowing from the ſame point of the object enter the pupil of the eye, in caſes where that divergency is conſiderable; but becauſe in what follows it will be neceſſary to ſuppoſe an object, when ſeen through a medium whereby its apparent diſtance is altered, to appear in ſome determinate ſituation, in thoſe caſes where the divergency of the rays at their entrance into the eye is conſiderable, we will ſuppoſe the object to appear where thoſe lines which they deſcribe in entering, if produced back, would croſs each other: though it muſt not be aſſerted, that this is the preciſe diſtance; becauſe the brightneſs, diſtinctneſs, and apparent magnitude of the object, on which its apparent diſtance in ſome meaſure depends, will alſo ſuffer an alteration by the refraction of the rays in paſſing through that medium.

Appearance of Objects ſeen though Media of different Forms.

3. That we eſtimate the magnitude of an object by that of the optic angle.

4. That viſion is the brighter, the greater the number of rays is which enter the pupil. And,

5. That, in ſome caſes, the apparent brightneſs, diſtinctneſs, and magnitude of an object, are the only means whereby our judgment is determined in eſtimating the diſtance of it.

Prop. I. An object placed within a medium terminated by a plane ſurface on that ſide which is next the eye, if the medium be denſer than that in which the eye is (as we ſhall always ſuppoſe it to be, unleſs where the contrary is expreſſed), appears nearer to the ſurface of the medium than it is.

Plate CCCLVIII.

Thus, if A be a point of an object placed within the medium BDCE (fig. 5.), and A*b* A*c* be two rays proceeding from thence, theſe rays paſſing out of a denſer into a rarer medium, will be refracted from their reſpective perpendiculars *bd*, *ce*, and will enter the eye at H, ſuppoſe in the directions *bf*, *cg*: let then theſe lines be produced back till they meet in F; this will be the apparent place of the point A; and becauſe the refracted rays *bf*, *cg* will diverge more than the incident ones A*b*, A*c*, it will be nearer to the points *b* and *c* than the point A; and as the ſame is true of each point in the object, the whole will appear to an eye at H, nearer to the ſurface BC than it is.

From hence it is, that when one end of a ſtraight ſtick is put under water, and the ſtick is held in an oblique poſition, it appears bent at the ſurface of the water; viz. becauſe each point that is under water appears nearer the ſurface, and conſequently higher than it is.

From hence likewiſe it is, that an object at the bottom of a veſſel may be ſeen when the veſſel is filled with water, though it be ſo placed with reſpect to the eye, that it cannot be ſeen when the veſſel is empty. To explain this, let ABCD (fig. 6.) repreſent a veſſel, and let E be an object lying at the bottom of it. This object, when the veſſel is empty, will not be ſeen by an eye at F, becauſe HB, the upper part of the veſſel, will obſtruct the ray EH; but when it is filled with water to the height GI, the ray at EK being refracted at the ſurface of the water into the line KF, the eye at F ſhall ſee the object by means of that.

166
An object ſituated in the horizon appears above its true place.

In like manner, an object ſituated in the horizon appears above its true place, upon account of the refraction of the rays which proceed from it in their paſſage through the atmoſphere of the earth. For, firſt, If the object be ſituated beyond the limits of the atmoſphere, its rays in entering it will be refracted towards

the

Appearance of Objects ſeen through Media of different Forms.

the perpendicular; that is, towards a line drawn from the point where they enter, to the centre of the earth, which is the centre of the atmoſphere: and as they paſs on, they will be continually refracted the ſame way, becauſe they are all along entering a denſer part, the centre of whoſe convexity is ſtill the ſame point; upon which account the line they deſcribe will be a curve bending downwards: and therefore none of the rays that come from that object can enter an eye upon the ſurface of the earth, except what enter the atmoſphere higher than they need to do if they could come in a right line from the object: conſequently the object muſt appear above its proper place. Secondly, If the object be placed within the atmoſphere, the caſe is ſtill the ſame; for the rays which flow from it muſt continually enter a denſer medium whoſe centre is below the eye; and therefore being refracted towards the centre, that is, downwards as before, thoſe which enter the eye muſt neceſſarily proceed as from ſome point above the object; wherefore the object will appear above its proper place.

From hence it is, that the ſun, moon, and ſtars, appear above the horizon, when they are juſt below it; and higher than they ought to do, when they are above it: Likewiſe diſtant hills, trees, &c. ſeem to be higher than they are.

Further, The lower theſe objects are in the horizon, the greater is the obliquity with which the rays which flow from them enter the atmoſphere, or paſs from the rarer into the denſer parts of it; and therefore they appear to be the more elevated by refraction: upon which account the lower parts of them are apparently more elevated than the other. This makes their upper and under parts ſeem nearer than they are; as is evident from the ſun and moon, which appear of an oval form when they are in the horizon, their horizontal diameters appearing of the ſame length they would do if the rays ſuffered no refraction, while their vertical ones are ſhortened thereby.

Prop. II. An object ſeen through a medium terminated by plane and parallel ſurfaces, appears nearer, brighter, and larger, than with the naked eye.

Plate CCLVIII.

167

An object ſeen thro' a plane medium appears nearer and brighter than ſeen by the naked eye.

For inſtance, let AB (fig. 7.) be the object, CDEF the medium, and GH the pupil of an eye, which is here drawn large to prevent confuſion in the figure.— And, 1ſt, let RK, RL, be two rays proceeding from the point R, and entering the denſer medium at K and L; theſe rays will here by refraction be made to diverge leſs, and to proceed afterwards, ſuppoſe in the lines K*a*, L*b*; at *a* and *b*, where they paſs out of the denſer medium, they will be as much refracted the contrary way, proceeding in the lines *ac*, *bd*, parallel to their firſt directions. Produce theſe lines back till they meet in *e*; this will be the apparent place of the point R; and it is evident from the figure, that it muſt be nearer the eye than that point; and becauſe the ſame is true of all other pencils flowing from the object AB, the whole will be ſeen in the ſituation *fg*, nearer to the eye than the line AB. 2d, As the rays RK, RL, would not have entered the eye, but have paſſed by it in the directions K*r*, L*t*, had they not been refracted in paſſing through the medium, the object appears brighter. 3d, The rays A*h*, B*i*, will be refracted at *h* and *i* into the leſs converging lines *hk*, *il*, and at the other ſurface into *k*M, *l*M, parallel to A*h* and B*i* produced; ſo that the extremities of the object will appear in the lines M*k*, M*l* produced, viz. in *f* and *g*, and under as large an angle *f*M*g*, as the angle A*q*B under which an eye at *q* would have ſeen it had there been no medium interpoſed to refract the rays; and therefore it appears larger to the eye at GH, being ſeen through the interpoſed medium, than otherwiſe it would have done. But it is here to be obſerved, that the nearer the point *e* appears to the eye on account of the refraction of the rays RK, RL, the ſhorter is the image *fg*, becauſe it is terminated by the lines M*f* and M*g*, upon which account the object is made to appear leſs; and therefore the apparent magnitude of an object is not much augmented by being ſeen through a medium of this form.

Farther, It is apparent from the figure, that the effect of a medium of this form depends wholly upon its thickneſs; for the diſtance between the lines R*r* and *ec*, and conſequently the diſtance between the points *e* and R, depends upon the length of the line K*a*:— Again, The diſtance between the lines AM and *f*M depends on the length of the line *hk*; but both K*a* and *hk* depend on the diſtance between the ſurfaces CE and DF, and therefore the effect of this medium depends upon its thickneſs.

Prop. III. An object ſeen through a convex lens, appears larger, brighter, and more diſtant, than with the naked eye.

168

Seen thro' a convex lens appears larger, brighter, and more diſtant.

To illuſtrate this, let AB (fig. 8.) be the object, CD the lens, and EF the eye. 1. From A and B, the extremities of the object, draw the lines AY*r*, BX*r*, croſſing each other in the pupil of the eye; the angle A*r*B comprehended between theſe lines, is the angle under which the object would be ſeen with the naked eye. But by the interpoſition of a lens of this form, whoſe property it is to render converging rays more ſo, the rays AY and BX will be made to croſs each other before they reach the pupil. There the eye at E will not perceive the extremities of the object by means of theſe rays (for they will paſs it without entering), but by ſome others which muſt fall without the points Y and X, or between them; but if they fall between them, they will be made to concur ſooner than they themſelves would have done; and therefore, if the extremities of the object could not be ſeen by them, it will much leſs be ſeen by theſe. It remains therefore, that the rays which will enter the eye from the points A and B after refraction, muſt fall upon the lens without the points Y and X; let then the rays AO and BP be ſuch. Theſe after refraction entering the eye at *r*, the extremities of the object will be ſeen in the lines *r*Q, *r*T, produced, and under the optic angle Q*r*T, which is larger than A*r*B, and therefore the apparent magnitude of the object will be increaſed.— 2. Let GHI be a pencil of rays flowing from the point G; as it is the property of this lens to render diverging rays leſs diverging, parallel, or converging, it is evident that ſome of thoſe rays, which would proceed on to F and E, and miſs the eye were they to ſuffer no refraction in paſſing through the lens, will now enter it; by which means the object will appear brighter. 3. As to the apparent diſtance of the object, that will vary according to the ſituation of it with reſpect to the focus of parallel rays of the lens.

1. Then

Appearance of objects ſeen through Media of different Forms.

1. Then, let us ſuppoſe the object placed ſo much nearer the lens than its focus of parallel rays, that the refracted rays KE and LF, though rendered leſs diverging by paſſing through it, may yet have a conſiderable degree of divergency, ſo that we may be able to form a judgment of the diſtance of the object thereby. In this caſe, the object ought to appear where EK, FL, produced back concur; which, becauſe they diverge leſs than the rays GH, GI, will be beyond G, that is, at a greater diſtance from the lens than the object is. But becauſe both the brightneſs and magnitude of the object will at the ſame time be augmented, prejudice will not permit us to judge it quite ſo far off as the point where thoſe lines meet, but ſomewhere between that point and its proper place. 2. Let the object be placed in the focus of parallel rays, then will the rays KE and LF become parallel; and though in this caſe the object would appear at an immenſe diſtance, if that diſtance were to be judged of by the direction of the rays KE and LF, yet upon account of the brightneſs and magnitude of it, we ſhall not think it much farther from us than if it were ſeen by the naked eye. 3. If the object be ſituated beyond the focus of parallel rays, as in BA (fig. 9.), the rays flowing from thence and falling upon the lens CD, will be collected into their reſpective foci at *a* and *b*, and the intermediate points *m*, *n*, &c. and will there form an image of the object AB; and after croſſing each other in the ſeveral points of it, as expreſſed in the figure, will paſs on diverging as from a real object. Now if an eye be ſituated at *c*, where A*c*, B*c*, rays proceeding from the extreme points of the object, make not a much larger angle A*c*B, than they would do if there were no lens interpoſed, and the rays belonging to the ſame pencil do not converge ſo much as thoſe which the eye would receive if it were placed nearer to *a* or *b*, the object upon theſe accounts appearing very little larger or brighter than with the naked eye, is ſeen nearly in its proper place: but if the eye recedes a little way towards *ab*, the object then appearing both brighter and larger, ſeems to approach the lens: which is an evident proof of what has been ſo often aſſerted, *viz.* that we judge of the diſtance of an object in ſome meaſure by its brightneſs and magnitude; for the rays converge the more the farther the eye recedes from the lens; and therefore if we judged of the diſtance of the object by the direction of the rays which flow from it, we ought in this caſe to conceive it at a greater diſtance, than when the rays were parallel, or diverged at their entrance into the eye.

Plate cccLVIII.

That the object ſhould ſeem to approach the lens in this caſe, was a difficulty that exceedingly puzzled the learned Barrow, and which he pronounces inſuperable, and not to be accounted for by any theory we have of viſion. Molineaux alſo leaves it to the ſolution of others, as that which will be inexplicable, till a more intimate knowledge of the viſive faculty, as he expreſſes it, be obtained by mortals.

They imagined, that ſeeing an object appears farther off, the leſs the rays diverge which fall upon the eye, if they ſhould proceed parallel to each other, it ought to appear exceeding remote; and if they ſhould converge, it ſhould then appear more diſtant ſtill: the reaſon of this was, becauſe they looked upon the apparent place of an object, as owing only to the direction of the rays whatever it was, and not at all to its apparent magnitude or ſplendour.

Appearance of Objects ſeen through Media of different Forms.

Perhaps it may proceed from our judging of the diſtance of an object in ſome meaſure by its magnitude, that that deception of ſight commonly obſerved by travellers may ariſe; *viz.* that upon the firſt appearance of a building larger than uſual, as a cathedral church, or the like, it generally ſeems nearer to them, than they afterwards find it to be.

169
In certain circumſtances an object ſeen through a convex lens appears inverted and pendulous in the air.

Prop. IV. If an object be placed farther from a convex lens than its focus of parallel rays, and the eye be ſituated farther from it on the other ſide than the place where the rays of the ſeveral pencils are collected into their reſpective foci, the object appears inverted, and pendulous in the air, between the eye and the lens.

To explain this, let AB (fig. 9.) repreſent the object, CD the lens; and let the rays of the pencil ACD be collected in *a*, and thoſe of BCD in *b*, forming there an inverted image of the object AB, and let the eye be placed in F: it is apparent from the figure, that ſome of the refracted rays which paſs through each point of the image will enter the eye as from a real object in that place; and therefore the object AB will appear there, as the propoſition aſſerts. But we are ſo little accuſtomed to ſee objects in this manner, that it is very difficult to perceive the image with one eye; but if both eyes are ſituated in ſuch a manner, that rays flowing from each point of the image may enter both, as at G and H, and we direct our optic axes to the image, it is eaſy to be perceived.

If the eye be ſituated in *a* or *b*, or very near them on either ſide, the object appears exceedingly confuſed, *viz.* if at *d*, the rays which proceed from the ſame point of the object converge ſo very much, and if at *e*, they diverge ſo much, that they cannot be collected together upon the retina, but fall upon it as if they were the axes of ſo many diſtinct pencils coming through every point of the lens; wherefore little more than one ſingle point of the object is ſeen at a time, and that appears all over the lens; from whence nothing but confuſion ariſes.

If the lens be ſo large that both eyes may be applied to it, as in *h* and *k*, the object will appear double; for it is evident from the figure, that the rays which enter the eye at *h* from either extremity of the object A or B, do not proceed as from the ſame point with that from whence thoſe which enter the other at *k* ſeem to flow; the mind therefore is here deceived, and looks upon the object as ſituated in two different places, and therefore judges it to be double.

170
An object through a concave lens is ſeen nearer, ſmaller, and leſs bright than with the naked eye.

Prop. V. An object ſeen through a concave lens appears nearer, ſmaller, and leſs bright, than with the naked eye.

Thus, let AB (fig. 10.) be the object, CD the pupil of an eye, and EF the lens. Now, as it is the property of a lens of this form to render diverging rays more ſo, and converging ones leſs ſo, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and ſo to enter the eye as from ſome nearer point *g*; and the rays AH, BI, which converge, will be made to converge leſs, and to enter the eye as from the points *a* and *b*; wherefore the objects will appear in the ſituation *a g b*, leſs and nearer than without the lens. Further, As the rays which proceed from G are rendered more diverging, ſome of them will be made to paſs by the pupil of the eye, which otherwiſe would have entered it, and therefore each point of the object will appear leſs bright.

Prop. VI. An object ſeen through a polygonous glaſs, that is, ſuch as is terminated by ſeveral plain ſurfaces, is multiplied thereby.

Plate CCCLVIII.

For inſtance, let A (fig. 11.) be an object, and BC a polygonous glaſs terminated by the plane ſurfaces BD, DE, &c. and let the ſituation of the eye F be ſuch, that the rays AB being refracted in paſſing through the glaſs, may enter it in the direction BF, and the rays AC in the direction CF. Then will the eye, by means of the former, ſee the object in G, and by the latter in H; and by means of the rays AI, the object will appear alſo in its proper ſituation A.

Sect. III. *Of the Reflection of Light.*

171 Some portion of light always reflected from tranſparent bodies.

When a ray of light falls upon any body, however tranſparent, the whole of it never paſſes through the body, but ſome part is always driven back or reflected from it; and it is by this reflected light that all bodies which have no light of their own become viſible to us. Of that part of the ray which enters, another part is alſo reflected from the ſecond ſurface, or that which is fartheſt from the luminous body. When this part arrives again at the firſt ſurface, part of it is reflected back from that ſurface; and thus it continues to be reflected between the two ſurfaces, and to paſs backwards and forwards within the ſubſtance of the medium, till ſome part is totally extinguiſhed and loſt. Beſides this inconſiderable quantity, however, which is loſt in this manner, the ſecond ſurface often reflects much more than the firſt; inſomuch that, in certain poſitions, ſcarce any rays will paſs through both ſides of the medium. A very conſiderable quantity is alſo unaccountably loſt or extinguiſhed at each reflecting ſurface; inſomuch that no body, however tranſparent, can tranſmit all the rays which fall upon it; neither, though it be ever ſo well fitted for reflection, will it reflect them all.

§ 1. *Of the Cauſe of Reflection.*

The reflection of light is by no means ſo eaſily accounted for as the refraction of the ſame fluid. This property, as we have ſeen in the laſt ſection, may be accounted for in a ſatisfactory manner by the ſuppoſition of an attractive power diffuſed throughout the medium, and extending a very little way beyond it; but with regard to the reflection of light, there ſeems to be no ſatisfactory hypotheſis hitherto invented. Of the principal opinions on this ſubject Mr Rowning hath given us the following account.

172 Light is not reflected by impinging on the ſolid parts of bodies at the firſt ſurface,

I. It was the opinion of philoſophers, before Sir Iſaac Newton diſcovered the contrary, that light is reflected by impinging upon the ſolid parts of bodies. But that it is not ſo, is clear for the following reaſons.

And, firſt, It is not reflected at the firſt ſurface of a body by impinging againſt it.

For it is evident, that, in order to the due and regular reflection of light, that is, that the reflected rays ſhould not be diſperſed and ſcattered one from another, there ought to be no raſures or unevenneſs in the reflecting ſurface large enough to bear a ſenſible proportion to the magnitude of a ray of light; becauſe if the ſurface abounds with ſuch, the reflected rays will rather be ſcattered like a parcel of pebbles thrown upon a rough pavement, than reflected with that regularity with which light is obſerved to be from a well poliſhed ſurface. Now thoſe ſurfaces, which to our ſenſes appear perfectly ſmooth and well poliſhed, are far from being ſo; for to poliſh, is no other than to grind off the larger eminences and protuberances of the metal with the rough and ſharp particles of ſand, emery, or putty, which muſt of neceſſity leave behind them an infinity of raſures and ſcratches, which, though inconſiderable with regard to the former roughneſſes, and too minute to be diſcerned by us, muſt nevertheleſs bear a large proportion to, if not vaſtly exceed, the magnitude of the particles of light.

173 nor at the ſecond.

Secondly, It is not reflected at the ſecond ſurface by impinging againſt any ſolid particles.

That it is not reflected by impinging upon the ſolid particles which conſtitute this ſecond ſurface, is ſufficiently clear from the foregoing argument; the ſecond ſurfaces of bodies being as incapable of a perfect poliſh as the firſt: and it is farther confirmed from hence, viz. that the quantity of light reflected differs according to the different denſity of the medium behind the body. And that it is not reflected by impinging upon the particles which conſtitute the ſurface of the medium behind it, is evident, becauſe the ſtrongeſt reflection of all at the ſecond ſurface of a body, is when there is a vacuum behind it. This therefore wants no farther proof.

174 Suppoſition of a repulſive force;

II. It has been thought by ſome, that it is reflected at the firſt ſurface of a body, by a repulſive force equally diffuſed over it: and at the ſecond, by an attractive force.

175 objected to.

1. If there be a repulſive force diffuſed over the ſurface of bodies that repels rays of light at all times, then, ſince by increaſing the obliquity of a ray we diminiſh its perpendicular force (which is that only whereby it muſt make its way through this repulſive force), however weakly that force may be ſuppoſed to act, rays of light may be made to fall with ſo great a degree of obliquity on the reflecting ſurface, that there ſhall be a total reflection of them there, and not one particle of light be able to make its way through: which is contrary to obſervation; the reflection of light at the firſt ſurface of a tranſparent body being never total in any obliquity whatever. The hypotheſis therefore in this particular muſt be falſe.

176 Attractive force ſuppoſed;

2. As to the reflection at the ſecond ſurface by the attractive force of the body; this may be conſidered in two reſpects: firſt, when the reflection is total; ſecondly, when it is partial.

And, firſt, In caſes where the reflection is total, the cauſe of it is undoubtedly that ſame attractive force by which light would be refracted in paſſing out of the ſame body. This is manifeſt from that analogy which is obſervable between the reflection of light at this ſecond ſurface, and its refraction there. For, otherwiſe, what can be the reaſon that the total reflection ſhould begin juſt when the obliquity of the incident ray, at its arrival at the ſecond ſurface, is ſuch, that the refracted angle ought to be a right one; or when the ray, were it not to return in reflection, ought to paſs on parallel to the ſurface, without going from it? For in this caſe it is evident, that it ought to be returned by this very power, and in ſuch manner that the angle of reflection ſhall be equal to the angle of incidence; juſt as a ſtone thrown obliquely from the earth, after it is ſo far turned out of its courſe by the attraction of the earth, as to begin to move horizontally, or parallel to the ſurface of the earth, is then by the ſame power made to return in a curve ſimilar to that which is deſcribed in its departure from the earth, and ſo falls with the ſame degree of obliquity that it was thrown with.

178 Objected to. But, ſecondly, As to the reflection at the ſecond ſurface, when it is partial; an attractive force uniformly ſpread over it, as the maintainers of this hypotheſis conceive it to be, can never be the cauſe thereof. Becauſe it is inconceivable, that the ſame force, acting in the ſame circumſtances in every reſpect, can ſometimes reflect the violet-coloured rays, and tranſmit the red, and at other times reflect the red and tranſmit the violet.'

We have ſtated this objection, becauſe it is our buſineſs to conceal no plauſible opinions: but it is not valid; for in each colour, the reflection takes place at that angle, and no other, where the refraction of *that* ray would make it parallel to the poſterior ſurface.

This partial reflection and refraction is a great difficulty in all the attempts which have been made to give a mechanical explanation of the phenomena of optics. It is equally a deſideratum in that explanation which was propoſed by Huygens, and, ſince his time, revived by Euler, by means of the undulations of an elaſtic fluid, although a vague conſideration of undulatory motions ſeems to offer a very ſpecious analogy. But a *rigid* application of ſuch *knowledge* as we have acquired of ſuch motions, will convince any unprejudiced mathematician, that the phenomena of undulation are eſſentially diſſimilar to the phenomena of light. The inflection of light, and its refraction, equally demonſtrate that light *is acted on* by moving forces in a direction perpendicular to the ſurface; and it is equally demonſtrable that ſuch forces muſt, in proper circumſtances, produce reflections preciſely ſuch as we obſerve. The only difficulty is to ſhow how there can be forces which produce both reflection and refraction, in circumſtances which are ſimilar. The fact is, that ſuch effects are produced: the firſt logical inference is, that with reſpect to the light which is reflected and that which is refracted, the circumſtances are *not* ſimilar; and our attention ſhould be directed to the diſcovery of that diſſimilarity. All the phenomena of combined reflection and refraction ſhould be examined and claſſed according to their generality, not doubting but that theſe points of reſemblance will lead to the diſcovery of their cauſes. Now the experiments of M. Bouguer ſhow that bodies differ extremely in their powers of thus ſeparating light by reflection and refraction, ſome of them reflecting much more at a given angle than others. It is not therefore *a general property of light* to be partly reflected and partly refracted, but a *diſtinctive* property of *different* bodies; and ſince we ſee that they poſſeſs it in *different* degrees, we are authorized to conclude that ſome bodies *may want it altogether*. We may therefore expect ſome ſucceſs by conſidering how bodies are affected by light, as well as how light is affected by bodies. Now, in all the phenomena of the material world we find bodies connected by mutual forces. We know no caſe where a body A tends towards a body B, or, in common language, is attracted by it, without, at the ſame time, the body B tending towards A. This is obſerved in the phenomena of magnetiſm, electricity, gravitation, corpuſcular attraction, impulſe, &c. We ſhould therefore conclude from analogy, that as bodies change the motion of light, light alſo changes the motion of bodies; and that the particles near the ſurface are put into vibration by the paſſage of light through among them.

178 The objection obviated. Suppoſe a parcel of cork balls all hanging as pendulums in a ſymmetrical order, and that an electrified ball paſſes through the midſt of them; it is very eaſy to ſhow that it may proceed through this aſſemblage in various directions with a ſinuated motion, and without touching any of them, and that its ultimate direction will have a certain inclination to its primary direction, depending on the outline of the aſſemblage, juſt as is obſerved in the motion of light; and, in the mean time, the cork balls will be variouſly agitated. Juſt ſo muſt it happen to the particles of a tranſparent body, if we ſuppoſe that they act on the particles of light by mutual attractions and repulſions.

An attentive conſideration of what happens here will ſhow us that the ſuperficial particles will be much more agitated than the reſt; and thus a ſtratum be produced, which, in any inſtant, will act on thoſe particles of light which are then approaching them in a manner different from that in which they will act on ſimilarly ſituated particles of light, which come into the place of the firſt in the following moment, when theſe acting particles of the body have (by their motion of vibration) changed their own ſituation. Now it is clearly underſtood, that, in all motions of vibration, ſuch as the motions of pendulums, there is a moment when the body is in its natural ſituation, as when the pendulum is in the vertical line. This *may* happen in the ſame inſtant in each atom of the tranſparent body. The particles of light which *then* come within the ſphere of action may be wholly reflected; in the next moment, particles of light in the very ſituation of the firſt may be refracted.

Then will ariſe a ſeparation of light; and as this will depend on the manner in which the particles of bodies are agitated by it during its paſſage, and as this again will depend on the nature of the body, that is, on the law of action of thoſe forces which connect the particles with each other, and with the particles of light, it will be different in different bodies. But in all bodies there will be this general reſemblance, that the ſeparation will be moſt copious in great obliquities of incidence, which gives the repulſive forces more time for action, while it diminiſhes the perpendicular force of the light. Such a reſemblance between the phenomena and the legitimate conſequences of the aſſumption (the agitation of the parts of the body), gives us ſome authority for aſſigning this as the cauſe; nor can the aſſumption

OPTICS.

[illegible]

tion be called *gratuitous*. To ſuppoſe that the particles of the tranſparent body *are not thus agitated*, would be a moſt gratuitous contradiction of a law of nature to which we know no other exception.

Thus the objection raiſed in N° 132. is obviated, becauſe the reflection and refraction are not here conceived as ſimultaneous, but as ſucceſſive.

179 Another Hypotheſis.

III. Some, being apprehenſive of the inſufficiency of a repulſive and attractive force diffuſed over the ſurfaces of bodies and acting uniformly, have ſuppoſed, that, by the action of light upon the ſurface of bodies, the matter of theſe bodies is put into an undulatory motion; and that where the ſurface of it is ſubſiding light is tranſmitted, and in thoſe places where it is riſing light is reflected. But to overlook the objections which we have juſt made to this theory of undulation, we have only to obſerve, that, were it admitted, it ſeems not to advance us one jot farther; for in thoſe caſes, ſuppoſe where red is reflected and violet tranſmitted, how comes it to paſs that the red impinges only on thoſe parts when the waves are riſing, and the violet when they are ſubſiding?

180 Sir I. Newton's Hypotheſis;

IV. The next hypotheſis that we ſhall take notice of, is that remarkable one of Sir Iſaac Newton's fits of eaſy reflection and tranſmiſſion, which we ſhall now explain and examine.

That author, as far as we can apprehend his meaning in this particular, is of opinion, that light in its paſſage from the luminous body, is diſpoſed to be alternately reflected by and tranſmitted through any refracting ſurface it may meet with; that theſe diſpoſitions (which he calls *fits of eaſy reflection and eaſy tranſmiſſion*) return ſucceſſively at equal intervals; and that they are communicated to it at its firſt emiſſion out of the luminous body it proceeds from, probably by ſome very ſubtile and elaſtic ſubſtance diffuſed through the univerſe, and that in the following manner. As bodies falling into water, or paſſing through the air, cauſe undulations in each, ſo the rays of light may excite vibrations in this elaſtic ſubſtance. The quickneſs of which vibrations depending on the elaſticity of the medium (as the quickneſs of the vibrations in the air, which propagate ſound, depend ſolely on the elaſticity of the air, and not upon the quickneſs of thoſe in the ſounding body), the motion of the particles of it may be quicker than that of the rays: and therefore, when a ray at the inſtant it impinges upon any ſurface, is in that part of a vibration of this elaſtic ſubſtance which conſpires with its motion, it may be eaſily tranſmitted; and when it is in that part of a vibration which is contrary to its motion, it may be reflected. He further ſuppoſes, that when light falls upon the ſurface of a body, if it be not in a fit of eaſy tranſmiſſion, every ray is there put into one, ſo that when they come at the other ſide (for this elaſtic ſubſtance, eaſily pervading the pores of bodies, is capable of the ſame vibrations within the body as without it), the rays of one colour ſhall be in a fit of eaſy tranſmiſſion, and thoſe of another in a fit of eaſy reflection, according to the thickneſs of the body, the intervals of the fits being different in rays of a different kind. This ſeems to account for the different colours of the bubble and thin plate of air and water, as is obvious enough; and likewiſe for the reflection of light at the ſecond ſurface of a thicker body; for the light reflected from thence is alſo obſerved to be coloured, and to form rings according to the different thickneſs of the body, when not intermixed and confounded with other light, as will appear from the following experiment. If a piece of glaſs be ground concave on one ſide and convex on the other, both its concavity and convexity having one common centre; and if a ray of light be made to paſs through a ſmall hole in a piece of paper held in that common centre, and be permitted to fall on the glaſs; beſides thoſe rays which are regularly reflected back to the hole again, there will be others reflected to the paper, and form coloured rings ſurrounding the hole, not unlike thoſe occaſioned by the reflection of light from thin plates.

181 Untenable.

It is ever with extreme reluctance that we venture to call in queſtion the doctrines of Newton; but to his theory of reflection there is this inſuperable objection, that it explains nothing, unleſs the *cauſe* of the fits of more eaſy reflection and tranſmiſſion be held as legitimate, namely, that *they are produced by the undulations of another elaſtic fluid, incomparably more ſubtile than light*, acting upon it in the way of impulſe. The fits themſelves are *matters of fact*, and no way different from what we have endeavoured to account for: but to admit this theory of them would be to tranſgreſs every rule of philoſophizing, as we have ſhown them to be ſuſceptible of explanation from acknowledged optical laws.

§ 2. *Of the Laws of Reflection.*

182 The fundamental law of Reflection.

The fundamental law of the reflection of light, is, that in all caſes the angle of reflection is equal to the angle of incidence. This is found by experiment to be the caſe, and beſides may be demonſtrated mathematically from the laws of percuſſion in bodies perfectly elaſtic. The axiom therefore holds good in every caſe of reflection, whether it be from plane ſurfaces or ſpherical ones, and that whether they are convex or concave; and hence the ſeven following propoſitions relating to the reflection of light from plane and ſpherical ſurfaces may be deduced.

I. Rays of light reflected from a plane ſurface have the ſame degree of inclination to one another that their reſpective incident ones have.—For the angle of reflection of each ray being equal to that of its reſpective incident one, it is evident, that each reflected ray will have the ſame degree of inclination to that portion of the ſurface from whence it is reflected that its incident one has; but it is here ſuppoſed, that all thoſe portions of ſurface from whence the rays are reflected, are ſituated in the ſame plane; conſequently the reflected rays will have the ſame degree of inclination to each other that their incident ones have, from whatever part of the ſurface they are reflected.

Plate CCCLIX.

183 Laws of reflection from a concave ſurface.

II. Parallel rays reflected from a concave ſurface are rendered converging.—To illuſtrate this, let AF, CD, EB, (fig. 1.) repreſent three parallel rays falling upon the concave ſurface FB, whoſe centre is C. To the points F and B draw the lines CF, CB; theſe being drawn from the centre, will be perpendicular to the ſurface at thoſe points. The incident ray CD alſo paſſing through the centre, will be perpendicular to the ſurface, and therefore will return after reflection in the ſame line; but the oblique rays AF and EB will be reflected into the lines FM and BM, ſituated on the contrary ſide of their reſpective perpendiculars CF and CB. They will therefore proceed converging after reflection towards ſome point, as M, in the line CD.

III. Converging rays falling on the like ſurface, are made to converge more.—For, every thing remaining as above, let GF, HB, be the incident rays. Now, becauſe theſe rays have larger angles of incidence than the parallel ones AF and EB in the foregoing caſe, their angles of reflection will alſo be larger than thoſe of the others; they will therefore converge after reflection, ſuppoſe in the lines FN and BN, having their point of concourſe N farther from the point C than M, that to which the parallel rays AF and EB converged to in the foregoing caſe; and their preciſe degree of convergency will be greater than that wherein they converged before reflection.

IV. Diverging rays falling upon the like ſurface, are, after reflection, parallel, diverging, or converging. If they diverge from the focus of parallel rays, they then become parallel; if from a point nearer to the ſurface than that, they will diverge, but in a leſs degree than before reflection; if from a point between that and the centre, they will converge after reflection, and that to ſome point on the contrary ſide of the centre, but ſituated farther from it than the point from which they diverged. If the incident rays diverge from a point beyond the centre, the reflected ones will converge to one on the other ſide of it, but nearer to it than the point they diverged from; and if they diverge from the centre, they will be reflected thither again.

1. Let them diverge in the lines MF, MB, proceeding from M, the focus of parallel rays; then, as the parallel rays AF and EB were reflected into the lines FM and BM (by Prop. II.), theſe rays will now on the contrary be reflected into them.

2. Let them diverge from N, a point nearer to the ſurface than the focus of parallel rays, they will then be reflected into the diverging lines FG and BH which the incident rays GF and HB deſcribed that were ſhown to be reflected into them in the foregoing propoſition; but the degree wherein they diverge will be leſs than that wherein they diverged before reflection.

3. Let them proceed diverging from X, a point between the focus of parallel rays and the centre; they then make leſs angles of incidence than the rays MF and MB, which became parallel by reflection: they will conſequently have leſs angles of reflection, and proceed therefore converging towards ſome point, as Y; which point will always fall on the contrary ſide of the centre, becauſe a reflected ray always falls on the contrary ſide of the perpendicular with reſpect to that on which its incident one falls; and of conſequence it will be farther diſtant from the centre than X.

4. If the incident ones diverge from Y, they will, after reflection, converge to X; thoſe which were the incident rays in the former caſe being the reflected ones in this. And, laſtly,

5. If the incident rays proceed from the centre, they fall in with their reſpective perpendiculars; and for that reaſon are reflected thither again.

Plate CCCLIX. 184

From a convex ſurface.

V. Parallel rays reflected from the convex ſurface are rendered diverging.—For, let AB, GD, EF, (fig. 2.) be three parallel rays falling upon the convex ſurface BF, whoſe centre of convexity is C, and let one of them, viz. GD, be perpendicular to the ſurface. Through B, D, and F, the points of reflection, draw the lines CV, CG, and CT; which, becauſe they paſs through the centre, will be perpendicular to the ſurface at theſe points. The incident ray GD being perpendicular to the ſurface, will return after reflection in the ſame line, but the oblique ones AB and EF in the lines BK and FL, ſituated on the contrary ſide of their reſpective perpendiculars BV and FT. They will therefore diverge, after reflection, as from ſome point M in the line GD produced; and this point will be in the middle between D and C.

VI. Diverging rays reflected from the like ſurface are rendered more diverging. For, every thing remaining as above, let GB, GF, be the incident rays. Theſe having larger angles of incidence than the parallel ones AB and EF in the preceding caſe, their angles of reflection will alſo be larger than theirs: they will therefore diverge after reflection, ſuppoſe in the lines BP and FQ, as from ſome point N, farther from C than the point M; and the degree wherein they will diverge will be greater than that wherein they diverged before reflection.

VII. Converging rays reflected from the like ſurface, are parallel, converging, or diverging. If they tend towards the focus of parallel rays, they then become parallel; if to a point nearer the ſurface than that, they converge, but in a leſs degree than before reflection; if to a point between that and the centre, they will diverge after reflection, as from ſome point on the contrary ſide of the centre, but ſituated farther from it than the point they converged to: if the incident rays converge to a point beyond the centre, the reflected ones will diverge as from one on the contrary ſide of it, but nearer to it than the point to which the incident ones converged; and if the incident rays converge towards the centre, the reflected ones will proceed as from thence.

1. Let them converge in the lines KB and LF, tending towards M, the focus of parallel rays; then, as the parallel rays AB, EF were reflected into the lines BK and FL (by Prop. V), thoſe rays will now on the contrary be reflected into them.

2. Let them converge in the lines PB, QF, tending towards N a point nearer the ſurface than the focus of parallel rays, they will then be reflected into the converging lines BG and FG, in which the rays GB, GF proceeded that were ſhown to be reflected into them by the laſt propoſition: but the degree wherein they will converge will be leſs than that wherein they converged before reflection.

3. Let them converge in the lines RB and SF proceeding towards X, a point between the focus of parallel rays and the centre; their angles of incidence will then be leſs than thoſe of the rays KB and LF, which became parallel after reflection: their angles of reflection will therefore be leſs; on which account they muſt neceſſarily diverge, ſuppoſe in the lines BH and FI, from ſome point, as Y; which point (by Prop. IV.) will fall on the contrary ſide of the

centre with reſpect to X, and will be farther from it than that.

4. If the incident rays tend towards Y, the reflected ones will diverge as from X; thoſe which were the incident ones in one caſe being the reflected ones in the other.

5. Laſtly, If the incident rays converge towards the centre, they fall in with their reſpective perpendiculars; on which account they proceed after reflection as from the centre.

We have already obſerved, that in ſome caſes there is a very great reflection from the ſecond ſurface of a tranſparent body. The degree of inclination neceſſary to cauſe a total reflection of a ray at the ſecond ſurface of a medium, is that which requires that the refracted angle (ſuppoſing the ray to paſs out there) ſhould be equal to or greater than a right one; and conſequently it depends on the refractive power of the medium through which the ray paſſes, and is therefore different in different media. When a ray paſſes through glaſs ſurrounded with air, and is inclined to its ſecond ſurface under an angle of 42 degrees or more, it will be wholly reflected there. For, as 11 is to 17 (the ratio of refraction out of glaſs into air), ſo is the ſine of an angle of 42 degrees to a fourth number that will exceed the ſine of a right angle. From hence it follows, that when a ray of light arrives at the ſecond ſurface of a tranſparent ſubſtance with as great or a greater degree of obliquity than that which is neceſſary to make a total reflection, it will there be all returned back to the firſt: and if it proceeds towards that with as great an obliquity as it did towards the other (which it will do if the ſurfaces of the medium be parallel to each other), it will there be all reflected again, &c. and will therefore never get out, but paſs from ſide to ſide, till it be wholly ſuffocated and loſt within the body.—From hence may ariſe an obvious inquiry, how it comes to paſs, that light falling very obliquely upon a glaſs window from without, ſhould be tranſmitted into the room. In anſwer to this it muſt be conſidered, that however obliquely a ray falls upon the ſurface of any medium whoſe ſides are parallel (as thoſe of the glaſs in a window are), it will ſuffer ſuch a degree of refraction in entering there, that it ſhall fall upon the ſecond with a leſs obliquity than that which is neceſſary to cauſe a total reflection. For inſtance, let the medium be glaſs, as ſuppoſed in the preſent caſe: then, as 17 is to 11 (the ratio of refraction out of air into glaſs), ſo is the ſine of the largeſt angle of incidence with which a ray can fall upon any ſurface to the ſine of a leſs angle than that of total reflection. And therefore, if the ſides of the glaſs be parallel, the obliquity with which a ray falls upon the firſt ſurface, cannot be ſo great, but that it ſhall paſs the ſecond without ſuffering a total reflection there.

When light paſſes out of a denſer into a rarer medium, the nearer the ſecond medium approaches the firſt in denſity (or more properly in its refractive power), the leſs of it will be refracted in paſſing from one to the other; and when their refracting powers are equal, all of it will paſs into the ſecond medium.

185
The preceding propoſitions demonſtrated mathematically.

The above propoſitions may be all mathematically demonſtrated in the following manner:

Prop. I. Of the reflection of rays from a plane ſurface.

"When rays fall upon a plane ſurface, if they diverge, the focus of the reflected rays will be at the ſame diſtance behind the ſurface, that the radiant point is before it: if they converge, it will be at the ſame diſtance before the ſurface that the imaginary focus of the incident rays is behind it."

This propoſition admits of two caſes.

Case 1. Of diverging rays.

Plate CCCLIX.

Dem. Let AB, AC, (fig. 3.) be two diverging rays incident on the plane ſurface DE, the one perpendicularly, the other obliquely: the perpendicular one AB will be reflected to A, proceeding as from ſome point in the line AB produced; the oblique one AC will be reflected into ſome line as CF, ſuch that the point G, where the line FG produced interſects the line AB produced alſo, ſhall be at an equal diſtance from the ſurface DE with the radiant A. For the perpendicular CH being drawn, ACH and HCF will be the angles of incidence and reflection; which being equal, their complements ACB and FCE are ſo too: but the angle BCG is equal to FCE, as being vertical to it: therefore in the triangles ABC and GBC the angles at C are equal, the ſide BC is common, and the angles at B are alſo equal to each other, as being right ones; therefore the lines AB and BG, which reſpect the equal angles at C, are alſo equal; and conſequently the point G, the focus of the incident rays AB, AC, is at the ſame diſtance behind the ſurface, that the point A is before it. *Q. E. D.*

Case 2. Of converging rays.

This is the converſe of the former caſe. For ſuppoſing FC and AB to be two converging incident rays, CA and BA will be the reflected ones (the angles of incidence in the former caſe being now the angles of reflection, and *vice verſa*), having the point A for their focus; but this, from what was demonſtrated above, is at an equal diſtance from the reflecting ſurface with the point G, which in this caſe is the imaginary focus of the incident rays FC and AB.

Obs. It is not here, as in the refraction of rays in paſſing through a plane ſurface, where ſome of the refracted rays proceed as from one point, and ſome as from another: but they all proceed after reflection as from one and the ſame point, however obliquely they may fall upon the ſurface; for what is here demonſtrated of the ray AC holds equally of any other, as AI, AK, &c.

The caſe of parallel rays incident on a plane ſurface is included in this propoſition: for in that caſe we are to ſuppoſe the radiant to be at an infinite diſtance from the ſurface, and then by the propoſition the focus of the reflected rays will be ſo too; that is, the rays will be parallel after reflection, as they were before.

Prop. II. Of the reflection of parallel rays from a ſpherical ſurface.

"When parallel rays are incident upon a ſpherical ſurface, the focus of the reflected rays will be the middle point between the centre of convexity and the ſurface."

This propoſition admits of two caſes.

Case 1. Of parallel rays falling upon a convex ſurface.

Dem. Let AB, DH, (fig. 4.) repreſent two parallel rays incident on the convex ſurface BH, the one perpendicularly, the other obliquely; and let C be the centre of convexity; ſuppoſe HE to be the reflected ray of the oblique incident one DH proceeding as from F, a point in the line AB produced. Through the point H draw the line CI, which will be perpendicular to the ſurface at that point; and the angles DHI and IHE, being the angles of incidence and reflection, will be equal. To the former of theſe, the angle HCF is equal, the lines AC and DH being parallel; and to the latter the angle CHF, as being vertical; wherefore the triangle CFH is iſoſceles, and conſequently the ſides CF and FH are equal: but ſuppoſing BH to vaniſh, FH is equal to FB; and therefore upon this ſuppoſition FC and FB are equal, that is, the focus of the reflected rays is the middle point between the centre of convexity and the ſurface. *Q. E. D.*

Case 2. Of parallel rays falling upon a concave ſurface.

Plate CCCLIX.

Dem. Let AB, DH, (fig. 5.) be two parallel rays incident, the one perpendicularly, the other obliquely, on the concave ſurface BH, whoſe centre of concavity is C. Let BF and HF be the reflected rays meeting each other in F; this will be the middle point between B and C. For drawing through C the perpendicular CH, the angles DHC and FHC, being the angles of incidence and reflection, will be equal, to the former of which the angle HCF is equal, as alternate; and therefore the triangle CFH is iſoſceles. Wherefore CF and FH are equal: but if we ſuppoſe BH to vaniſh, FB and FH are alſo equal, and therefore CF is equal to FB; that is, the focal diſtance of the reflected rays is the middle point between the centre and the ſurface. *Q. E. D.*

Obs. It is here obſervable, that the farther the line DH, either in fig. 4. or 5. is taken from AB, the nearer the point F falls to the ſurface. For the farther the point H recedes from B, the larger the triangle CFH will become; and conſequently, ſince it is always an iſoſceles one, and the baſe CH, being the radius, is everywhere of the ſame length, the equal legs CF and FH will lengthen; but CF cannot grow longer unleſs the point F approach towards the ſurface. And the farther H is removed from B, the faſter F approaches to it.

This is the reaſon, that whenever parallel rays are conſidered as reflected from a ſpherical ſurface, the diſtance of the oblique one from the perpendicular one is taken ſo ſmall with reſpect to the focal diſtance of that ſurface, that without any phyſical error it may be ſuppoſed to vaniſh.

186
Reflected rays from a ſpherical ſurface never proceed from the ſame point.

From hence it follows, that if a number of parallel rays, as AB, CD, EG, &c. fall upon a convex ſurface, (as fig. 6.) and if BA, DK, the reflected rays of the incident ones AB, CD, proceed as from the point F, thoſe of the incident ones CD, EG, viz. DK, GL, will proceed as from N, thoſe of the incident ones EG, HI, as from O, &c. becauſe the farther the incident ones CD, EG, &c. are from AB, the nearer to the ſurface are the points F, *f*, *f*, in the line BF, from which they proceed after reflection; ſo that properly the foci of the reflected rays BA, DK, GL, &c. are not in the line AB produced, but in a curve line paſſing through the points F, N, O, &c.

The ſame is applicable to the caſe of parallel rays reflected from a concave ſurface, as expreſſed by the pricked lines on the other half of the figure, where PQ, RS, TV, are the incident rays; QF, S*f*, V*f*, the reflected ones, interſecting each other in the points X, Y, and F; ſo that the foci of thoſe rays are not in the line FB, but in a curve paſſing through thoſe points.

187
Rays proceeding from one point, and falling on a parabolic concave ſurface, are all reflected from one point.

Had the ſurface BH in fig. 4. or 5. been formed by the revolution of a parabola about its axis having its focus in the point F, all the rays reflected from the convex ſurface would have proceeded as from the point F, and thoſe reflected from the concave would have fallen upon it, however diſtant their incident ones AB, DH, might have been from each other. For in the parabola, all lines drawn parallel to the axis make angles with the tangents to the points where they cut the parabola (that is, with the ſurface of the parabola) equal to thoſe which are made with the ſame tangents by lines drawn from thence to the focus; therefore, if the incident rays deſcribe thoſe parallel lines, the reflected ones will neceſſarily deſcribe theſe other, and ſo will all proceed as from, or meet in, the ſame point.

Prop. III. Of the reflection of diverging and converging rays from a ſpherical ſurface.

188
Proportional diſtance of the focus of rays reflected from a ſpherical ſurface.

"When rays fall upon any ſpherical ſurface, if they diverge, the diſtance of the focus of the reflected rays from the ſurface is to the diſtance of the radiant point from the ſame (or, if they converge, to that of the imaginary focus of the incident rays), as the diſtance of the focus of the reflected rays from the centre is to the diſtance of the radiant point (or imaginary focus of the incident rays) from the ſame."

This propoſition admits of ten caſes.

Case 1. Of diverging rays falling upon a convex ſurface.

Dem. Let RB, RD, (fig. 7.) repreſent two diverging rays flowing from the point R as from a radiant, and falling the one perpendicularly, the other obliquely, on the convex ſurface BD, whoſe centre is C. Let DE be the reflected ray of the incident one RD, produce ED to F, and through R draw the line RH parallel to FE till it meets CD produced in H. Then will the angle RHD be equal to EDH the angle of reflection, as being alternate to it, and therefore equal alſo to RDH which is the angle of incidence; wherefore the triangle DRH is iſoſceles, and conſequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are ſimilar, (or, to expreſs it in Euclid's way, the ſides of the triangle RHC are cut proportionably, 2 Elem. 6.): and therefore FD is to RH, or its equal RD, as CF to CR; but BD vaniſhing, FD and RD differ not from FB and RB: wherefore FB is to RB alſo, as CF to CR; that is, the diſtance of the focus from the ſurface is to the diſtance of the radiant point from the ſame, as the diſtance of the focus from the centre is to the diſtance of the radiant from thence. *Q. E. D.*

Case 2. Of converging rays falling upon a concave ſurface.

Dem. Let KD and CB be the converging incident rays having their imaginary focus in the point R, which was the radiant in the foregoing caſe. Then as RD was in that caſe reflected into DE, KD will in this be reflected into DF; for, ſince the angles of incidence in both caſes are equal, as they are by being vertical, the angles of reflection will be ſo too; ſo that F will be the focus of the reflected rays: but it was there demonſtrated, that FB is to RB as CF to CR; that is, the diſtance of the focus from the ſurface is to the diſtance (in this caſe) of the imaginary focus of the incident rays, as the diſtance of the focus from the centre is to the diſtance of the imaginary focus of the incident rays from the ſame. *Q. E. D.*

Case 3. Of converging rays falling upon a convex ſurface, and tending to a point between the focus of parallel rays and the centre.

Plate CCCLIX.

Dem. Let BD (fig. 8.) repreſent a convex ſurface whoſe centre is C, and whoſe focus of parallel rays is P; and let AB, KD, be two converging rays incident upon it, and having their imaginary focus at R, a point between P and C. Now becauſe KD tends to a point between the focus of parallel rays and the centre, the reflected ray DE will diverge from ſome point on the other ſide the centre, ſuppoſe F; as explained above (p. 308.) under Prop. 7. Through D draw the perpendicular CD and produce it to H; then will KDH and HDE be the angles of incidence and reflection, which being equal, their vertical ones RDC and CDF will be ſo too, and therefore the vertex of the triangle RDF is biſected by the line DC: wherefore (3 El. 6.) FD and DR, or BD vaniſhing, FB and BR are to each other as FC to CR; that is, the diſtance of the focus of the reflected rays is to that of the imaginary focus of the incident ones, as the diſtance of the former from the centre is to the diſtance of the latter from the ſame. *Q. E. D.*

Case 4. Of diverging rays falling upon a concave ſurface, and proceeding from a point between the focus of parallel rays and the centre.

Dem. Let RB, RD, (fig. 8.) be the diverging rays incident upon the concave ſurface BD, having their radiant point in the point R, the imaginary focus of the incident rays in the foregoing caſe. Then as KD was in that caſe reflected into DE, RD will now be reflected into DF. But it was there demonſtrated, that FB and RB are to each other as CF to CR; that is, the diſtance of the focus is to that of the radiant as the diſtance of the former from the centre is to the diſtance of the latter from the ſame. *Q. E. D.*

The angles of incidence and reflection being equal, it is evident, that if, in any caſe, the reflected ray be made the incident one, the incident will become the reflected one; and therefore the four following caſes may be conſidered reſpectively as the converſe of the four foregoing; for in each of them the incident rays are ſuppoſed to coincide with the reflected ones in the other. Or they may be demonſtrated independently of them, as follows.

Case 5. Of converging rays falling upon a convex ſurface, and tending to a point nearer the ſurface than the focus of parallel rays.

Dem. Let ED, RB (fig. 7.) be the converging rays incident upon the convex ſurface BD whoſe centre is C, and focus of parallel rays is P; and let the imaginary focus of the incident rays be at F, a point between P and B; and let DR be the reflected ray. From C and R draw the lines CH, RH, the one paſſing through D, the other parallel to FE. Then will the angle RHD be equal to HDE the angle of incidence, as alternate to it; and therefore equal to HDR, the angle of reflection: wherefore the triangle HDR is iſoſceles, and conſequently DR is equal to RH. Now the lines FD and RH being parallel, the triangles FDC and RHC are ſimilar; and therefore RH, or RD, is to FD as CR to CF: but BD vaniſhing, RD and FD coincide with RB and FB, wherefore RB is to FB as CR to CF; that is, the diſtance of the focus from the ſurface is to the diſtance of the imaginary focus of the incident rays, as the diſtance of the focus from the centre is to the diſtance of the imaginary focus of the incident rays from the ſame. *Q. E. D.*

Case 6. Of diverging rays falling upon a concave ſurface, and proceeding from a point between the focus of parallel rays and the ſurface.

Dem. Let FD and FB repreſent two diverging rays flowing from the point F as a radiant, which was the imaginary focus of the incident rays in the foregoing caſe. Then as ED was in that caſe reflected into DR, FD will be reflected into DK (for the reaſon mentioned in Caſe 2.), ſo that the reflected ray will proceed as from the point R: but it was demonſtrated in the caſe immediately foregoing, that RB is to FB as CR to CF; that is, the diſtance of the focus from the ſurface is to that of the radiant from the ſame, as the diſtance of the former from the centre is to that of the latter from the ſame. *Q. E. D.*

Case 7. Of converging rays falling upon a convex ſurface, and tending towards a point beyond the centre.

Dem. Let AB, ED (fig. 8.) be the incident rays tending to F, a point beyond the centre C, and let DK be the reflected ray of the incident one ED. Then becauſe the incident ray ED tends to a point beyond the centre, the reflected ray DK will proceed as from one on the contrary ſide, ſuppoſe R; as explained above under Prop. VII. Through D draw the perpendicular CD, and produce it to H. Then will EDH and HDK be the angles of incidence and reflection; which being equal, their vertical ones CDF and CDR will be ſo too: conſequently the vertex of the triangle FDR is biſected by the line CD: wherefore, RD is to DF, or (3 Elem. 6.) BD vaniſhing, RB is to BF as RC to CF; that is, the diſtance of the focus of the reflected rays is to that of the imaginary focus of the incident rays, as the diſtance of the former from the centre is to the diſtance of the latter from the ſame. *Q. E. D.*

Case 8. Of diverging rays falling upon a concave ſurface, and proceeding from a point beyond the centre.

Dem. Let FB, FD, be the incident rays having their radiant in F, the imaginary focus of the incident rays in the foregoing caſe. Then as ED was in that caſe reflected into DK, FD will now be reflected into DR; ſo that R will be the focus of the reflected rays. But it was demonſtrated in the foregoing caſe, that RB is to FB as RC to CF; that is, the diſtance of the focus of the reflected rays from the ſurface is to the diſtance of the radiant from the ſame, as the diſtance of the focus of the reflected rays from the centre is to the diſtance of the radiant from thence. *Q. E. D.*

The two remaining caſes may be conſidered as the converſe of thoſe under Prop. II. (p. 309, 310.), becauſe the

Laws of Reflection.

the incident rays in theſe are the reflected ones in them; or they may be demonſtrated in the ſame manner with the foregoing, as follows.

Case 9. Converging rays falling upon a convex ſurface, and tending to the focus of parallel rays, become parallel after reflection.

Plate CCCLIX.

Dem. Let ED, RB (fig. 7.) repreſent two converging rays incident on the convex ſurface BD, and tending towards F, which we will now ſuppoſe to be the focus of parallel rays: and let DR be the reflected ray, and C the centre of convexity of the reflecting ſurface. Through C draw the line CD, and produce it to H, drawing RH parallel to ED produced to F. Now it has been demonſtrated (Caſe 5. where the incident rays are ſuppoſed to tend to the point F), that RB is to FB as RC to CF; but F in this Caſe being ſuppoſed to be the focus of parallel rays, it is the middle point between C and B (by Prop. II.) and therefore FB and FC are equal; and conſequently the two other terms in the proportion, *viz* RB and RC, muſt be ſo too; which can only be upon the ſuppoſition that R is at an infinite diſtance from B; that is, that the reflected rays BR and DR be parallel. *Q. E. D.*

Case 10. Diverging rays falling upon a concave ſurface, and proceeding from the focus of parallel rays, become parallel after reflection.

Dem. Let RD, RB, (fig. 8.) be two diverging rays incident upon the concave ſurface BD, as ſuppoſed in Caſe 4. where it was demonſtrated that FB is to RB as CF to CR. But in the preſent caſe RB and CR are equal, becauſe R is ſuppoſed to be the focus of parallel rays; therefore FB and FC are ſo too; which cannot be unleſs F be taken at an infinite diſtance from B; that is, unleſs the reflected rays BF and DF be parallel. *Q. E. D.*

Obs. It is here obſervable, that in the caſe of diverging rays falling upon a convex ſurface (ſee fig. 7.), the farther the point D is taken from B, the nearer the point F, the focus of the reflected rays, approaches to B, while the radiant R remains the ſame. For it is evident from the curvature of a circle, that the point D (fig. 9.) may be taken ſo far from B, that the reflected ray DE ſhall proceed as from F, G, H, or even from B, or from any point between B and R; and the farther it is taken from B, the faſter the point from which it proceeds approaches towards R: as will eaſily appear if we draw ſeveral incident rays with their reſpective reflected ones, in ſuch manner that the angles of reflection may be all equal to their reſpective angles of incidence, as is done in the figure. The like is applicable to any of the other caſes of diverging or converging rays incident upon a ſpherical ſurface. This is the reaſon, that, when rays are conſidered as reflected from a ſpherical ſurface, the diſtance of the oblique rays from the perpendicular one is taken ſo ſmall, that it may be ſuppoſed to vaniſh.

From hence it follows, that if a number of diverging rays are incident upon the convex ſurface BD at the ſeveral points B, D, D,.&c. they ſhall not proceed after reflection as from any point in the line RB produced, but as from a curve line paſſing through the ſeveral points F, *f*, *f*, &c. The ſame is applicable in all the other caſes.

Laws of Reflection

Had the curvature BD (fig. 7.) been hyperbolical, having its foci in R and F, then R being the radiant (or the imaginary focus of incident rays), F would have been the focus of the reflected ones, and *vice verſa*, however diſtant the points B and D might be taken from each other. In like manner, had the curve BD (fig. 8) been elliptical, having its foci in F and R, the one of theſe being made the radiant (or imaginary focus of incident rays), the other would have been the focus of reflected ones, and *vice verſa*. For both in the hyperbola and ellipſis, lines drawn from each of their foci through any point make equal angles with the tangent to that point. Therefore, if the incident rays proceed to or from one of their foci, the reflected ones will all proceed as from or to the other. So that, in order that diverging or converging rays may be accurately reflected to or from a point, the reflecting ſurface muſt be formed by the revolution of an *hyperbola* about its longer axis, when the incident rays are ſuch, that their radiant or imaginary focus of incident rays ſhall fall on one ſide the ſurface, and the focus of the reflected ones on the other; when they are both to fall on the ſame ſide, it muſt be formed by the revolution of an *ellipſis* about its longer axis. However, upon account of the great facility with which ſpherical ſurfaces are formed, in compariſon of that with which ſurfaces formed by the revolution of any of the conic ſections about their axes are made, the latter are very rarely uſed. Add to this another inconvenience, *viz.* that the foci of theſe curves being mathematical points, it is but one point of the ſurface of an object that can be placed in any of them at a time; ſo that it is only in theory that ſurfaces formed by the revolution of theſe curves about their axes render reflection perfect.

189 Method of finding the focal diſtance of rays reflected from a convex ſurface.

Now, becauſe the focal diſtance of rays reflected from a ſpherical ſurface cannot be found by the analogy laid down in the third propoſition, without making uſe of the quantity ſought; we ſhall here give an inſtance whereby the method of doing it in all others will readily appear.

Prob. Let it be required to find the focal diſtance of diverging rays incident upon a convex ſurface, whoſe radius of convexity is 5 parts, and the diſtance of the radiant from the ſurface is 20.

Sol. Call the focal diſtance ſought x; then will the diſtance of the focus from the centre be $5-x$, and that of the radiant from the ſame 25, therefore by Prop. 3. we have the following proportion. *viz.* $x : 20 :: 5-x : 25$; and multiplying extremes together and means together, we have $25x = 100-20x$, which, after due reduction, gives $x=\frac{100}{45}$.

If in any caſe it ſhould happen that the value of x ſhould be a negative quantity, the focal point muſt then be taken on the contrary ſide of the ſurface to that on which it was ſuppoſed that it would fall in ſtating the problem.

If letters inſtead of figures had been made uſe of in the foregoing ſolution, a general theorem might have been raiſed, to have determined the focal diſtance of reflected rays in all caſes whatever. See this done in Suppl. to *Gregory's Optics*, 2d Edit. p. 112

Becauſe it was, in the preceding ſection, obſerved, that different incident rays, though tending to or from one point, would after refraction proceed to or from

The Appearance of Bodies ſeen by Reflection.

different points, a method was there inſerted of determining the diſtinct point which each ſeparate ray entering a ſpherical ſurface converges to, or diverges from, after refraction: the ſame has been obſerved here with regard to rays reflected from a ſpherical ſurface (ſee Obſ. in Caſe 2. and Caſe 10.) But the method of determining the diſtinct point to or from which any given incident ray proceeds after reflection, is much more ſimple. It is only neceſſary to draw the reflected ray ſuch, that the angle of reflection may be equal to the angle of incidence, which will determine the point it proceeds to or from in any caſe whatever.

§ 3. *Of the Appearance of Bodies ſeen by Light reflected from plane and ſpherical Surfaces.*

Whatever has been ſaid concerning the appearance of bodies ſeen by refracted light through lenſes, reſpects alſo the appearance of bodies ſeen by reflection. But beſides theſe, there is one thing peculiar to images by reflection, viz. that each point in the repreſentation of an object made by reflection appears ſituated ſomewhere in an infinite right line that paſſes through its correſpondent point in the object, and is perpendicular to the reflecting ſurface.

The truth of this appears ſufficiently from the propoſitions formerly laid down: in each of which, rays flowing from any radiant point, are ſhown to proceed after reflection to or from ſome point in a line that paſſes through the ſaid radiant, and is perpendicular to the reflecting ſurface. For inſtance (fig. 1.), rays flowing from Y are collected in X, a point in the perpendicular CD, which, being produced, paſſes through Y: again (fig. 2.), rays flowing from G, proceed, after reflection, as from N, a point in the perpendicular CD, which, being produced, paſſes through G; and ſo of the reſt.

Plate CCCLIX.

This obſervation, however, except where an object is ſeen by reflection from a plain ſurface, relates only to thoſe caſes where the repreſentation is made by means of ſuch rays as fall upon the reflecting ſurface with a very ſmall degree of obliquity; becauſe ſuch as fall at a conſiderable diſtance from the perpendicular, proceed not after reflection as from any point in that perpendicular, but as from other points ſituated in a certain curve, as hath already been explained; upon which account theſe rays are neglected, as making a confuſed and deformed repreſentation. And therefore it is to be remembered, that however the ſituation of the eye with reſpect to the object and reflecting ſurface may be repreſented in the following figures, it is to be ſuppoſed as ſituated in ſuch a manner with reſpect to the object, that rays flowing from thence and entering it after reflection, may be ſuch only as fall with a very ſmall degree of obliquity upon the ſurface; that is, the eye muſt be ſuppoſed to be placed almoſt directly behind the object, or between it and the reflecting ſurface. The reaſon why it is not always ſo placed, is only to avoid confuſion in the figures.

190 The appearance of objects reflected from plane ſurfaces.

I. When an object is ſeen by reflection from a plane ſurface, the image of it appears at the ſame diſtance behind the ſurface that the object is placed before it, of the ſame magnitude therewith, and directly oppoſite to it.

The Appearance of Bodies ſeen by Reflection.

To explain this, let AB (fig. 10.) repreſent an object ſeen by reflection from the plane ſurface SV; and let the rays AF, AG, be ſo inclined to the ſurface, that they ſhall enter an eye at H after reflection; and let AE be perpendicular to the ſurface: then, by the obſervation juſt mentioned, the point A will appear in ſome part of the line AE produced, ſuppoſe I; that is, the oblique rays AF and AG will proceed after reflection as from that point: and further, becauſe the reflected rays FH, GK, will have the ſame degree of inclination to one another that their incident ones have, that point muſt neceſſarily be at the ſame diſtance from the ſurface that the point A is; the repreſentation therefore of the point A will be at the ſame diſtance behind the ſurface that the point itſelf is before it, and directly oppoſite to it: conſequently, ſince the like may be ſhown of the point B, or of any other, the whole image IM will appear at the ſame diſtance behind the ſurface that the object is before it, and directly oppoſite to it; and becauſe the lines AI, BM, which are perpendicular to the plain ſurface, are for that reaſon parallel to each other, it will alſo be of the ſame magnitude therewith.

191 From convex ſurfaces; and

II. When an object is ſeen by reflection from a convex ſurface, its image appears nearer to the ſurface, and leſs than the object.

Let AB (fig. 12.) repreſent the object, SV a reflecting ſurface whoſe centre of convexity is C: and let the rays AF, AG, be ſo inclined to the ſurface, that after reflection therefrom, they ſhall enter the eye at H: and let AE be perpendicular to the ſurface; then will the oblique rays AF, AG, proceed after reflection as from ſome point in the line AE produced, ſuppoſe from I; which point, becauſe the reflected rays will diverge more than the incident ones, muſt be nearer to the ſurface then the point A. And ſince the ſame is alſo true of the rays which flow from B, or any other point, the repreſentation IM will be nearer to the ſurface than the object; and becauſe it is terminated by the perpendiculars AE and BF, which incline to each other, as concurring at the centre, it will alſo appear leſs.

192 From concave ſurfaces.

III. When an object is ſeen by reflection from a concave ſurface, the repreſentation of it is various, both with regard to its magnitude and ſituation, according as the diſtance of the object from the reflecting ſurface is greater or leſs.

1. When the object is nearer to the ſurface than its focus of parallel rays, the image falls on the oppoſite ſide of the ſurface, is more diſtant from it, and larger than the object.

Thus, let AB (fig. 13.) be the object, SV the reflecting ſurface, F the focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE, CR, which will be perpendicular to the ſurface; and let the rays AR, AG, be incident upon ſuch points of it that they ſhall be reflected into an eye at H. Now, becauſe the radiant points A and B are nearer the ſurface than F the focus of parallel rays, the reflected rays will diverge, and will therefore proceed as from ſome points on the oppoſite ſide of the ſurface; which points, by the obſervation laid down at the beginning of this ſection, will be in the perpendiculars AE, BR, produced, ſuppoſe in I and M: but they will diverge in a leſs degree than their incident ones (ſee the propoſition juſt referred to); and therefore the ſaid points will be farther from the ſurface than the points A and B. The image therefore will be on the oppoſite ſide of the ſurface with reſpect to the object: it will be more diſtant than it; and conſequently being terminated by the perpendiculars CI and CM, it will alſo be larger.

2. When the object is placed in the focus of parallel rays, the reflected rays enter the eye parallel; in which caſe the image ought to appear at an infinite diſtance behind the reflecting ſurface: but the repreſentation of it, for the like reaſons that were given in the foregoing caſe, being large and diſtinct, we judge it not much farther from the ſurface than the image.

3. When the object is placed between the focus of parallel rays and the centre, the image falls on the oppoſite ſide of the centre, is larger than the object, and in an inverted poſition.

Plate CCLIX.

Thus let AB (fig. 14.) repreſent the object, SV the reflecting ſurface, F its focus of parallel rays, and C its centre. Through A and B, the extremities of the object, draw the lines CE and CN, which will be perpendicular to the ſurface; and let AR, AG, be a pencil of rays flowing from A. Theſe rays proceeding from a point beyond the focus of parallel rays, will after reflection converge towards ſome point on the oppoſite ſide the centre, which will fall upon the perpendicular EC produced, but at a greater diſtance from C than the radiant A from which they diverged. For the ſame reaſon, rays flowing from B will converge to a point in the perpendicular NC produced, which ſhall be farther from C than the point B; from whence it is evident, that the image IM is larger than the object AB, that it falls on the contrary ſide the centre, and that their poſitions are inverted with reſpect to each other.

4. If the object be placed beyond the centre of convexity, the image is then formed between the centre and the focus of parallel rays, is leſs than the object, and its poſition is inverted.

This propoſition is the converſe of the foregoing: for as in that caſe rays proceeding from A were reflected to I, and from B to M; ſo rays flowing from I and M will be reflected to A and B; if therefore an object be ſuppoſed to be ſituated beyond the centre in IM, the image of it will be formed in AB between that and the focus of parallel rays, will be leſs than the object, and inverted.

5. If the middle of the object be placed in the centre of convexity of the reflecting ſurface, the object and its image will be coincident; but the image will be inverted with reſpect to the object.

That the place of the image and the object ſhould be the ſame in this caſe needs little explication; for the middle of the object being in the centre, rays flowing from thence will fall perpendicularly upon the ſurface, and therefore neceſſarily return thither again; ſo that the middle of the image will be coincident with the middle of the object. But that the image ſhould be inverted is perhaps not ſo clear. To explain this, let AB (fig. 15.) be the object, having its middle point C in the centre of the reflecting ſurface from SV; through the centre and the point R draw the line CR, which will be perpendicular to the reflecting ſurface; join the points AR and BR, and let AR repreſent a ray flowing from A; this will be reflected into RB: for C being the middle point between A and B, the angles ARC and CRB are equal; and a ray from B will likewiſe be reflected to A; and therefore the poſition of the image will be inverted with reſpect to that of the object.

In this propoſition it is to be ſuppoſed, that the object AB is ſo ſituated with reſpect to the reflecting ſurface, that the angle ACR may be right; for otherwiſe the angles ARC and BRC will not be equal, and part of the image will therefore fall upon the object and part off.

6. If in any of the three laſt caſes, in each of which the image is formed on the ſame ſide of the reflecting ſurface with the object, the eye be ſituated farther from the ſurface than the place where the image falls, the rays of each pencil, croſſing each other in the ſeveral points of the image, will enter the eye as from a real object ſituated there; ſo that the image will appear pendulous in the air between the eye and the reflecting ſurface, and in the poſition wherein it is formed, viz. inverted with reſpect to the object, in the ſame manner that an image formed by refracted light appears to an eye placed beyond it; which was fully explained under Prop. IV. (p. 304.), and therefore needs not be repeated.

But as what relates to the appearance of the object when the eye is placed nearer to the ſurface than the image, was not there fully inquired into, that point ſhall now be more ſtrictly examined under the following caſe, which equally relates to refracted and reflected light.

7. If the eye be ſituated between the reflecting ſurface and the place of the image, the object is then ſeen beyond the ſurface; and the farther the eye recedes from the ſurface towards the place of the image, the more confuſed, larger, and nearer, the object appears.

To explain this, let AB (fig. 16.) repreſent the object; IM its image, one of whoſe points M is formed by the concurrence of the reflected rays DM, EM, &c. which before reflection came from B; the other, I, by the concurrence of DI, EI, &c. which came from A: and let *ab* be the pupil of an eye, ſituated between the ſurface DP and the image. This pupil will admit the rays H*a*, K*b*; which, becauſe they are tending towards I, are ſuch as came from A, and therefore the point A will appear diffuſed over the ſpace RS. In like manner the pupil will alſo receive into it the reflected rays K*a* and L*b*, which, becauſe they are tending towards M, by ſuppoſition came from B; and therefore the point B will be ſeen ſpread as it were over the ſpace TV, and the object will ſeem to fill the ſpace RV; but the repreſentation of it will be confuſed, becauſe the intermediate points of the object being equally enlarged in appearance, there will not be room for them between the points S and T, but they will coincide in part one with another: for inſtance, the appearance of that point in the object, whoſe repreſentation falls upon *c* in the image, will fill the ſpace *mn*; and ſo of the reſt. Now, if the ſame pupil be removed into the ſituation *e f*, the reflected rays E *e* and G *f* will then enter the eye, and therefore one extremity of the object will appear to cover the ſpace XY; and becauſe the rays O *f* and L *e* will alſo enter it in their progreſs towards M, the point B, from whence they came, will appear to cover ZV; the object therefore will appear larger and more confuſed than before. And when the eye recedes quite to the image, it ſees but one ſingle point of the object, and that appears diffuſed all over the reflecting ſurface: for inſtance, if the eye recedes to the point M, then rays flowing from the point B enter it upon whatever part of the ſurface they fall; and ſo for the reſt. The object alſo appears nearer to the ſurface the farther the eye recedes from it towards the place of the image; probably becauſe, as the appearance of the object becomes more and more confuſed, its place is not ſo eaſily diſtinguiſhed from that of the reflecting ſurface itſelf, till at laſt when it is quite confuſed (as it is when the eye is arrived at M) they both appear as one, the ſurface aſſuming the colour of the object.

193
The apparent magnitude of an object ſeen by reflection from a concave ſurface.

As to the preciſe apparent magnitude of an object ſeen after this manner, it is ſuch that the angle it appears under ſhall be equal to that which the image of the ſame object would appear under were we to ſuppoſe it ſeen from the ſame place: that is, the apparent object (for ſuch we muſt call it, to diſtinguiſh it from the image of the ſame object) and the image ſubtend equal angles at the eye.

Dem. Here we muſt ſuppoſe the pupil of the eye to be a point only, becauſe the magnitude of that cauſes ſmall alteration in the apparent magnitude of the object; as we ſhall ſee by and by. Let then the point *a* repreſent the pupil, then will the extreme rays that can enter it be H *a* and K *a*; the object therefore will appear under the angle H *a* K, which is equal to its vertical one M *a* I, under which the image IM would appear were it to be ſeen from *a*. Again, If the eye be placed in *f*, the object appears under the angle G *f* O equal to I *f* M, which the image ſubtends at the ſame place, and therefore the apparent object and image of it ſubtend equal angles at the eye. *Q. E. D.*

Now if we ſuppoſe the pupil to have any ſenſible magnitude, ſuch, ſuppoſe, that its diameter may be *a b*; then the object ſeen by the eye in that ſituation will appear under the angle HXL, which is larger than the angle H *a* K, under which it appeared before; becauſe the angle at X is nearer than the angle at *a*, to the line IM, which is a ſubtenſe common to them both.

From this propoſition it follows; that, were the eye cloſe to the ſurface at K, the real and apparent object would be ſeen under equal angles (for the real object appears from that place under the ſame angle that the image does, as will be ſhown at the end of this ſection); therefore, when the eye is nearer to the image than that point, the image will ſubtend a larger angle at it than the object does; and conſequently, ſince the image and apparent object ſubtend equal angles at the eye, the apparent object muſt neceſſarily be ſeen under a larger angle than the object itſelf, wherever the eye be placed, between the ſurface and the image.

As each point in the repreſentation of an object made by reflection is ſituated ſomewhere in a right line that paſſes through its correſpondent point in the object, and is perpendicular to the reflecting ſurface, as was ſhown in the beginning of this ſection; we may from hence deduce a moſt eaſy and expeditious method of determining both the magnitude and ſituation of the image in all caſes whatever. Thus,

Plate CCCLIX.

Through the extremities of the object AB and the centre C (fig. 17, 18, or 19.) draw the lines AC BC, and produce them as the caſe requires; theſe lines will be perpendicular to the reflecting ſurface, and therefore the extremities of the image will fall upon them. Through F the middle point of the object and the centre, draw the line FC, and produce it till it paſſes through the reflecting ſurface; this will alſo be perpendicular to the ſurface. Through G, the point where this line cuts the ſurface, draw the lines AG and BG, and produce them this way or that, till they croſs the former perpendiculars; and where they croſs, there I and M the extremities of the image will fall. For ſuppoſing AG to be a ray proceeding from the point A and falling upon G, it will be reflected to B; becauſe FA is equal to FB, and FG is perpendicular to the reflecting ſurface; and therefore the repreſentation of the point A will be in BG produced as well as in AC; conſequently it will fall on the point I, where they croſs each other. Likewiſe the ray BG will for the ſame reaſon be reflected to A; and therefore the repreſentation of the point B will be in AG produced, as well as in ſome part of BC, that is, in M where they croſs. From whence the propoſition is clear.

If it happens that the lines will not croſs which way ſoever they are produced, as in (fig. 20), then is the object in the focus of parallel rays of that ſurface, and has no image formed in the place whatever. For in this caſe the rays AH, AG, flowing from the point A, become parallel after reflection in the lines HC, GB, and therefore do not flow as to or from any point: in like manner, rays flowing from B are reflected into the parallel lines KB and GA; ſo that no repreſentation can be formed by ſuch reflection.

From hence we learn another circumſtance relating to the magnitude of the image made by reflection; viz. that it ſubtends the ſame angle at the vertex of the reflecting ſurface that the object does. This appears by inſpection of the 17th, 18th, or 19th figure, in each of which the angle IGM, which the image ſubtends at G the vertex of the reflecting ſurface, is equal to the angle AGB, which the object ſubtends at the ſame place; for in the two firſt of thoſe figures they are vertical, in the third they are the ſame. And,

Further, The angle ICM, which the image ſubtends at the centre, is alſo equal to the angle ACB which the object ſubtends at the ſame place; for in the two firſt figures they are the ſame, in the laſt they are vertical to each other.

From whence it is evident, that the object and its image are to each other in diameter, either as their reſpective diſtances from the vertex of the reflecting ſurface, or as their diſtances from the centre of the ſame.

Light differently refrangible.

IV. As objects are multiplied by being ſeen thro' tranſparent media, whoſe ſurfaces are properly diſpoſed, ſo they may alſo by reflecting ſurfaces. Thus,

Plate CCLIX.

1. If two reflecting ſurfaces be diſpoſed at right angles, as the ſurfaces AB, BC, (fig. 21.), an object at D may be ſeen by an eye at E, after one reflection at F, in the line EF produced; after two reflections, the firſt at G, the ſecond at H, in the line EH produced; and alſo, after one reflection made at A, in the line EA produced.

2. If the ſurfaces be parallel, as AB, CD, (fig. 22.), and the object be placed at E and the eye at F, the object will appear multiplied an infinite number of times: thus it may be ſeen in the line FG produced, after one reflection at G; in the line FH produced, after two reflections, the firſt at I, the ſecond at H; and alſo in FP produced, after ſeveral ſucceſſive reflections of the ray EL, at the points L, M, N, O, and P; and ſo on *in infinitum*. But the greater the number of reflections are, the weaker their repreſentation will be.

SECT. IV. *Of the different Refrangibility of Light.*

As this property of light ſolves a great number of the phenomena which could not be underſtood by former opticians, we ſhall give an account of it in the words of Sir Iſaac Newton, who firſt diſcovered it; eſpecially as his account is much more full, clear, and perſpicuous, than thoſe of ſucceeding writers.

Plate CCLX.

"In a very dark chamber, at a round hole F (fig. 1.), about one third of an inch broad, made in the ſhut of a window, I placed a glaſs priſm ABC, whereby the beam of the ſun's light, SF, which came in at that hole, might be refracted upwards, toward the oppoſite wall of the chamber, and there form a coloured image of the ſun, repreſented at PT. The axis of the priſm (that is, the line paſſing through the middle of the priſm, from one end of it to the other end, parallel to the edge of the refracting angle) was in this and the following experiments perpendicular to the incident rays. About this axis I turned the priſm ſlowly, and ſaw the refracted light on the wall, or coloured image of the ſun, firſt to deſcend, and then to aſcend. Between the deſcent and aſcent, when the image ſeemed ſtationary, I ſtopped the priſm and fixed it in that poſture.

"Then I let the refracted light fall perpendicularly upon a ſheet of white paper, MN, placed at the oppoſite wall of the chamber, and obſerved the figure and dimenſions of the ſolar image, PT, formed on the paper by that light. This image was oblong, and not oval, but terminated by two rectilinear and parallel ſides and two ſemicircular ends. On its ſides it was bounded pretty diſtinctly; but on its ends very confuſedly and indiſtinctly, the light there decaying and vaniſhing by degrees. At the diſtance of 18½ feet from the priſm the breadth of the image was about 2⅛ inches, but its length was about 10¾ inches, and the length of its rectilinear ſides about 8 inches; and ACB, the refracting angle of the priſm, whereby ſo great a length was made, was 64 degrees. With a leſs angle the length of the image was leſs, the breadth remaining the ſame. It is farther to be obſerved, that the rays went on in ſtraight lines from the priſm to the image, and therefore at their going out of the priſm had all that inclination to one another from which the length of the image proceeded. This image PT was coloured, and the more eminent colours lay in this order from the bottom at T to the top at P; red, orange, yellow, green, blue, indigo, violet; together with all their intermediate degrees in a continual ſucceſſion perpetually varying."

194 Light conſiſts of ſeveral ſorts of coloured rays differently refrangible.

Our author concludes from this experiment, and many more to be mentioned hereafter, "that the light of the ſun conſiſts of a mixture of ſeveral ſorts of coloured rays, ſome of which at equal incidences are more refracted than others, and therefore are called *more refrangible*. The red at T, being neareſt to the place Y, where the rays of the ſun would go directly if the priſm was taken away, is the leaſt refracted of all the rays; and the orange, yellow, green, blue, indigo, and violet, are continually more and more refracted, as they are more and more diverted from the courſe of the direct light. For by mathematical reaſoning he has proved, that when the priſm is fixed in the poſture above-mentioned, ſo that the place of the image ſhall be the loweſt poſſible, or at the limit between its deſcent and aſcent, the figure of the image ought then to be round like the ſpot at Y, if all the rays that tended to it were equally refracted. Therefore, ſeeing by experience it is found that this image is not round, but about five times longer than broad, it follows, that all the rays are not equally refracted. And this concluſion is farther confirmed by the following experiments.

"In the ſun-beam SF (fig. 2.), which was propagated into the room thro' the hole in the window-ſhut EG, at the diſtance of ſome feet from the hole, I held the priſm ABC in ſuch a poſture, that its axis might be perpendicular to that beam: then I looked through the priſm upon the hole F, and turning the priſm to and fro about its axis to make the image *p t* of the hole aſcend and deſcend, when between its two contrary motions it ſeemed ſtationary, I ſtopped the priſm; in this ſituation of the priſm, viewing through it the ſaid hole E, I obſerved the length of its refracted image *p t* to be many times greater than its breadth; and that the moſt refracted part thereof appeared violet at *p*; the leaſt refracted red, at *t*; and the middle parts indigo, blue, green, yellow, and orange, in order. The ſame thing happened when I removed the priſm out of the ſun's light, and looked through it upon the hole ſhining by the light of the clouds beyond it. And yet if the refractions of all the rays were equal according to one certain proportion of the ſines of incidence and refraction, as is vulgarly ſuppoſed, the refracted image ought to have appeared round, by the mathematical demonſtration above-mentioned. So then by theſe two experiments it appears, that in equal incidences there is a conſiderable inequality of refractions."

For the diſcovery of this fundamental property of light, which has opened the whole myſtery of colours, we ſee our author was not only beholden to the experiments themſelves, which many others had made before him, but alſo to his ſkill in geometry; which was abſolutely neceſſary to determine what the figure of the refracted image ought to be upon the old principle of an equal refraction of all the rays: but hav-

people in ſeeing all theſe experiments would be apt to frame. For the rays, to ſpeak properly, are not coloured. In them there is nothing elſe than a certain power and diſpoſition to ſtir up a ſenſation of this or that colour. For as ſound, in a bell or muſical ſtring or other ſounding body, is nothing but a trembling motion, and in the air nothing but that motion propagated from the object, and in the ſenſorium it is a ſenſe of that motion under the form of ſound; ſo colours in the object are nothing but a diſpoſition to reflect this or that ſort of rays more copiouſly than the reſt: in rays they are nothing but their diſpoſitions to propagate this or that motion into the ſenſorium; and in the ſenſorium they are ſenſations of thoſe motions under the forms of colours. See CHROMATICS.

197 Why the image of the ſun, by heteroge[illegible] paſſing through a priſm, is oblong. Plate CCCLX.

“By the mathematical propoſition above-mentioned, it is certain that the rays which are equally refrangible do fall upon a circle anſwering to the ſun's apparent diſk, which will alſo be proved by experiment by and by. Now let AG (fig. 5.) repreſent the circle which all the moſt refrangible rays, propagated from the whole diſk of the ſun, will illuminate and paint upon the the oppoſite wall if they were alone; EL the circle, which all the leaſt refrangible rays would in like manner illuminate if they were alone; BH, CI, DK, the circles which ſo many intermediate ſorts would paint upon the wall, if they were ſingly propagated from the ſun in ſucceſſive order, the reſt being intercepted; and conceive that there are other circles without number, which innumerable other intermediate ſorts of rays would ſucceſſively paint upon the wall, if the ſun ſhould ſucceſſively emit every ſort apart. And ſeeing the ſun emits all theſe ſorts at once, they muſt all together illuminate and paint innumerable equal circles; of all which, being according to their degrees of refrangibility placed in order in a continual ſeries, that oblong ſpectrum PT is compoſed, which was deſcribed in the firſt experiment.

“Now if theſe circles, whilſt their centres keep their diſtances and poſitions, could be made leſs in diameter, their interfering one with another, and conſequently the mixture of the heterogeneous rays, would be proportionably diminiſhed. Let the circles AG, BH, CI, &c. remain as before; and let *ag*, *bh*, *ci*, &c. be ſo many leſs circles lying in a like continual ſeries, between two parallel right lines *ae* and *gl*, with the ſame diſtance between their centres, and illuminated with the ſame ſorts of rays: that is, the circle *ag* with the ſame ſort by which the correſponding circle AG was illuminated; and the reſt of the circles *bh*, *ci*, *dk*, *el* reſpectively with the ſame ſorts of rays by which the correſponding circles BH, CI, DK, EL, were illuminated. In the figure PT, compoſed of the great circles, three of thoſe, AG, BH, CI, are ſo expanded into each other, that three ſorts of rays, by which thoſe circles are illuminated, together with innumerable other ſorts of intermediate rays, are mixed at QR in the middle of the circle BH. And the like mixture happens throughout almoſt the whole length of the figure PT. But in the figure *pt*, compoſed of the leſs circles, the three leſs circles *ag*, *bh*, *ci*, which anſwer to thoſe three greater, do not extend into one another; nor are there anywhere mingled ſo much as any two of the three ſorts of rays by which thoſe circles are illuminated, and which in the figure PT are all of them intermingled at QR. So then, if we would diminiſh the mixture of the rays, we are to diminiſh the diameters of the circles. Now theſe would be diminiſhed if the ſun's diameter, to which they anſwer, could be made leſs than it is, or (which comes to the ſame purpoſe) if without doors, at great diſtance from the priſm towards the ſun, ſome opaque body were placed with a round hole in the middle of it to intercept all the ſun's light, except ſo much as coming from the middle of his body could paſs through that hole to the priſm. For ſo the circles AG, BH, and the reſt, would not any longer anſwer to the whole diſk of the ſun, but only to that part of it which could be ſeen from the priſm through that hole; that is, to the apparent magnitude of that hole viewed from the priſm. But that theſe circles may anſwer more diſtinctly to that hole, a lens is to be placed by the priſm to caſt the image of the hole (that is, every one of the circles AG, BH, &c.) diſtinctly upon the paper at PT; after ſuch a manner, as by a lens placed at a window the pictures of objects abroad are caſt diſtinctly upon a paper within the room. If this be done, it will not be neceſſary to place that hole very far off, no not beyond the window. And therefore, inſtead of that hole, I uſed the hole in the window-ſhut as follows:

“In the ſun's light let into my darkened chamber through a ſmall round hole in my window-ſhut, at about 10 or 12 feet from the window, I placed a lens MN (fig. 6.), by which the image of the hole F might be diſtinctly caſt upon a ſheet of white paper placed at I. Then immediately after the lens I placed a priſm ABC, by which the trajected light might be refracted either upwards or ſidewiſe, and thereby the round image which the lens alone did caſt upon the paper at I, might be drawn out into a long one with parallel ſides, as repreſented at *pt*. This oblong image I let fall upon another paper at about the ſame diſtance from the priſm as the image at I, moving the paper either towards the priſm or from it, until I found the juſt diſtance where the rectilinear ſides of the images *pt* become moſt diſtinct. For in this caſe the circular images of the hole, which compoſe that image, after the manner that the circles *ag*, *bh*, *ci*, &c. do the figure *pt*, were terminated moſt diſtinctly, and therefore extended into one another the leaſt that they could, and by conſequence the mixture of the heterogeneous rays was now the leaſt of all. The circles *ag*, *bh*, *ci*, &c. which compoſe the image *pt*, are each equal to the circle at I; and therefore, by diminiſhing the hole F, or by removing the lens farther from it, may be diminiſhed at pleaſure, whilſt their centres keep the ſame diſtances from each other. Thus, by diminiſhing the breadth of the image *pt*, the circles of heterogeneal rays that compoſe it may be ſeparated from each other as much as you pleaſe. Yet inſtead of the circular hole F, it is better to ſubſtitute an oblong hole ſhaped like a parallelogram, with its length parallel to the length of the priſm. For if this hole be an inch or two long, and but a 10th or 20th part of an inch broad, or narrower, the light of the image *pt* will be as ſimple as before, or ſimpler; and the image being much broader, is therefore fitter to have experiments tried in its light than before.

“Homogeneal light is refracted regularly without any dilatation, ſplitting, or ſhattering of the rays; and the confuſed viſion of objects ſeen through refracting bodies by heterogeneal light, ariſes from the different refrangibility of ſeveral ſorts of rays. This will appear by the experiments which will follow. In the middle of a black paper I made a round hole about a fifth or a ſixth part of an inch in diameter. Upon this part I cauſed the ſpectrum of homogeneal light, deſcribed in the former article, ſo to fall that ſome part of the light might paſs through the hole in the paper. This tranſmitted part of the light, I refracted with a priſm placed behind the paper: and letting the refracted light fall perpendicularly upon a white paper, two or three feet diſtant from the priſm, I found that the ſpectrum formed on the paper by this light was not oblong, as when it is made in the firſt experiment, by refracting the ſun's compound light, but was, ſo far as I could judge by my eye, perfectly circular, the length being nowhere greater than the breadth; which ſhows that this light is refracted regularly without any dilatation of the rays, and is an ocular demonſtration of the mathematical propoſition mentioned above.

198
The image of the ſun, by ſimple and homogeneous light, circular.

"In the homogeneal light I placed a paper circle of a quarter of an inch in diameter: and in the ſun's unrefracted, heterogeneal, white light, I placed another paper circle of the ſame bigneſs; and going from theſe papers to the diſtance of ſome feet, I viewed both circles through a priſm. The circle illuminated by the ſun's heterogeneal light appeared very oblong, as in the ſecond experiment, the length being many times greater than the breadth. But the other circle, illuminated with homogeneal light appeared circular, and diſtinctly defined, as when it is viewed by the naked eye; which proves the whole propoſition mentioned in the beginning of this article.

199
Viſion more diſtinct in homogeneal than in heterogeneous light.

"In the homogeneal light I placed flies and ſuch like minute objects, and viewing them through a priſm I ſaw their parts as diſtinctly defined as if I had viewed them with the naked eye. The ſame objects placed in the ſun's unrefracted heterogeneal light, which was white, I viewed alſo through a priſm, and ſaw them moſt confuſedly defined, ſo that I could not diſtinguiſh their ſmaller parts from one another. I placed alſo the letters of a ſmall print one while in the homogeneal light, and then in the heterogeneal; and viewing them through a priſm, they appeared in the latter caſe ſo confuſed and indiſtinct that I could not read them; but in the former, they appeared ſo diſtinct that I could read readily, and thought I ſaw them as diſtinct as when I viewed them with my naked eye: in both caſes, I viewed the ſame objects through the ſame priſm, at the ſame diſtance from me, and in the ſame ſituation. There was no difference but in the lights by which the objects were illuminated, and which in one caſe was ſimple, in the other compound; and therefore the diſtinct viſion in the former caſe, and confuſed in the latter, could ariſe from nothing elſe than from that difference in the lights. Which proves the whole propoſition.

"In theſe three experiments, it is farther very remarkable, that the colour of homogeneal light was never changed by the refraction. And as theſe colours were not changed by refractions, ſo neither were they by reflections. For all white, gray, red, yellow, green, blue, violet, bodies, as paper, aſhes, red lead, orpiment, indigo, bice, gold, ſilver, copper, graſs, blue flowers, violets, bubbles of water tinged with various colours, peacock feathers, the tincture of lignum nephriticum, and ſuch like, in red homogeneal light appeared totally red, in blue light totally blue, in green light totally green, and ſo of other colours. In the homogeneal light of any colour they all appeared totally of that ſame colour; with this only difference, that ſome of them reflected that light more ſtrongly, others more faintly. I never yet found any body which by reflecting homogeneal light could ſenſibly change its colour.

"From all which it is manifeſt, that if the ſun's light conſiſted of but one ſort of rays, there would be but one colour in the world, nor would it be poſſible to produce any new colour by reflections and refractions; and by conſequence, that the variety of colours depends upon the compoſition of light.

"The ſolar image *pt*, formed by the ſeparated rays in the 5th experiment, did in the progreſs from its end *p*, on which the moſt refrangible rays fell, unto its end *t*, on which the leaſt refrangible rays fell, appear tinged with this ſeries of colours; violet, indigo, blue, green, yellow, orange, red, together with all their intermediate degrees in a continual ſucceſſion perpetually varying; ſo that there appeared as many degrees of colours as there were ſorts of rays differing in refrangibility. And ſince theſe colours could not be changed by refractions nor by reflections, it follows, that all homogeneal light has its proper colour anſwering to its degree of refrangibility.

160
Every homogeneal ray is refracted according to one and the ſame rule.

"Every homogeneal ray conſidered apart is refracted, according to one and the ſame rule; ſo that its ſine of incidence is to its ſine of refraction in a given ratio: that is, every different coloured ray has a different ratio belonging to it. This our author has proved by experiment, and by other experiments has determined by what numbers thoſe given ratios are expreſſed. For inſtance, if an heterogeneal white ray of the ſun emerges out of glaſs into air; or, which is the ſame thing, if rays of all colours be ſuppoſed to ſucceed one another in the ſame line AC, and AD (fig. 15.) their common ſine of incidence in glaſs be divided into 50 equal parts, then EF and GH, the ſines of refraction into air, of the leaſt and moſt refrangible rays, will be 77 and 78 ſuch parts reſpectively. And ſince every colour has ſeveral degrees, the ſines of refraction of all the degrees of red will have all intermediate degrees of magnitude from 77 to $77\frac{1}{8}$, of all the degrees of orange from $77\frac{1}{8}$ to $77\frac{1}{5}$, of yellow from $77\frac{1}{5}$ to $77\frac{1}{3}$, of green from $77\frac{1}{3}$ to $77\frac{1}{2}$, of blue from $77\frac{1}{2}$ to $77\frac{2}{3}$, of indigo from $77\frac{2}{3}$ to $77\frac{7}{9}$, and of violet from $77\frac{7}{9}$ of 78."

Plate CCLX.

PART II.

SECT. I. *The Application of the foregoing Theory to ſeveral natural Phenomena.*

§ 1. *Of the Rainbow.*

THIS beautiful phenomenon hath engaged the attention of all ages. By ſome nations it hath been deified; though the more ſenſible part always looked upon it as a natural appearance, and endeavoured, however imperfectly, to account for it. The obſervations of the ancients and philoſophers of the middle ages concerning the rainbow were ſuch as could not have eſcaped the notice of the moſt illiterate huſbandmen who gazed at the ſky; and their various hypotheſes deſerve no notice. It was a conſiderable time even after the dawn of true philoſophy in this weſtern part of the world, before we find any diſcovery of importance on this ſubject. Maurolycus was the firſt who pretended to have meaſured the diameters of the two rainbows with much exactneſs; and he reports that he found that of the inner bow to be 45 degrees, and that of the outer bow 56; from which Deſcartes takes occaſion to obſerve, how little we can depend upon the obſervations of thoſe who were not acquainted with the cauſe of the appearances.

201
Knowledge of the nature of the rainbow a modern diſcovery.

One *Clichtovæus* (the ſame, it is probable, who diſtinguiſhed himſelf by his oppoſition to Luther, and who died in 1543) had maintained, that the ſecond bow is the image of the firſt, as he thought was evident from the inverted order of the colours. For, ſaid he, when we look into the water, all the images that we ſee reflected by it are inverted with reſpect to the objects themſelves; the tops of the trees, for inſtance, that ſtand near the brink, appearing lower than the roots.

That the rainbow is oppoſite to the ſun, had always been obſerved. It was, therefore, natural to imagine, that the colours of it were produced by ſome kind of reflection of the rays of light from drops of rain, or vapour. The regular order of the colours was another circumſtance that could not have eſcaped the notice of any perſon. But, notwithſtanding mere reflection had in no other caſe been obſerved to produce colours, and it could not but have been obſerved that refraction is frequently attended with that phenomenon, yet no perſon ſeems to have thought of having recourſe to a proper refraction in this caſe, before one *Fletcher* of Breſlaw, who, in a treatiſe which he publiſhed in 1571, endeavoured to account for the colours of the rainbow by means of a double refraction and one reflection. But he imagined that a ray of light, after entering a drop of rain, and ſuffering a refraction both at its entrance and exit, was afterwards reflected from another drop, before it reaches the eye of the ſpectator. He ſeems to have overlooked the reflection at the farther ſide of the drop, or to have imagined that all the bendings of the light within the drop would not make a ſufficient curvature to bring the ray of the ſun to the eye of the ſpectator. That he ſhould think of two refractions, was the neceſſary conſequence of his ſuppoſing that the ray entered the drop at all. This ſuppoſition, therefore, was all the light that he threw upon the ſubject. B. Porta ſuppoſed that the rainbow is produced by the refraction of light in the whole body of rain or vapour, but not in the ſeparate drops.

202
Approach towards it made by Fletcher of Breſlaw.

After all, it was a man whom no writers allow to have had any pretenſions to philoſophy, that hit upon this curious diſcovery. This was Antonio De Dominis, biſhop of Spalatro, whoſe treatiſe *De Radiis Viſus et Lucis*, was publiſhed by J. Bartolus in 1611. He firſt advanced, that the double refraction of Fletcher, with an intervening reflection, was ſufficient to produce the colours of the bow, and alſo to bring the rays that formed them to the eye of the ſpectator, without any ſubſequent reflection. He diſtinctly deſcribes the progreſs of a ray of light entering the upper part of the drop, where it ſuffers one refraction, and after being thereby thrown upon the back part of the inner ſurface, is from thence reflected to the lower part of the drop; at which place undergoing a ſecond refraction, it is thereby bent, ſo as to come directly to the eye. To verify this hypotheſis, this perſon (no philoſopher as he was) proceeded in a very ſenſible and philoſophical manner. For he procured a ſmall globe of ſolid glaſs, and viewing it when it was expoſed to the rays of the ſun, in the ſame manner in which he had ſuppoſed that the drops of rain were ſituated with reſpect to them, he actually obſerved the ſame colours which he had ſeen in the true rainbow, and in the ſame order.

203
The diſcovery made by Antonio de Dominis, biſhop of Spalatro.

Thus the circumſtances in which the colours of the rainbow were formed, and the progreſs of a ray of light through a drop of water, were clearly underſtood; but philoſophers were a long time at a loſs when they endeavoured to aſſign reaſons for all the particular colours, and for the order of them. Indeed nothing but the doctrine of the different refrangibility of the rays of light, which was a diſcovery reſerved for the great Sir Iſaac Newton, could furniſh a complete ſolution of this difficulty. De Dominis ſuppoſed that the red rays were thoſe which had traverſed the leaſt ſpace in the inſide of a drop of water, and therefore retained more of their native force, and conſequently, ſtriking the eye more briſkly, gave it a ſtronger ſenſation; that the green and blue colours were produced by thoſe rays, the force of which had been, in ſome meaſure, obtunded in paſſing through a greater body of water; and that all the intermediate colours were compoſed (according to the hypotheſis which generally prevailed at that time) of a mixture of theſe three primary ones. That the different colours were cauſed by ſome difference in the impulſe of light upon the eye, and the greater or leſs impreſſion that was thereby made upon it, was an opinion which had been adopted by many perſons, who had ventured to depart from the authority of Ariſtotle.

Afterwards the ſame De Dominis obſerved, that all the rays of the ſame colour muſt leave the drop of water in a part ſimilarly ſituated with reſpect to the eye, in order that each of the colours may appear in a circle, the centre of which is a point of the heavens, in a line drawn from the ſun through the eye of the ſpectator. The red rays, he obſerved, muſt iſſue from the drop neareſt to the bottom of it, in order that the circle of red may be the outermoſt, and therefore the moſt elevated in the bow.

Notwithſtanding De Dominis conceived ſo juſtly of the manner in which the inner rainbow is formed, he was far from having as juſt an idea of the cauſe of the exterior bow. This he endeavoured to explain in the very ſame manner in which he had done the interior, viz. by one reflection of the light within the drop, preceded and followed by a refraction; ſuppoſing only that the rays which formed the exterior bow were returned to the eye by a part of the drop lower than that which tranſmitted the red of the interior bow. He alſo ſuppoſed that the rays which formed one of the bows came from the ſuperior part of the ſun's diſk, and thoſe which formed the other from the inferior part of it. He did not conſider, that upon thoſe principles, the two bows ought to have been contiguous; or rather, that an indefinite number of bows would have had their colours all intermixed; which would have been no bow at all.

When Sir Iſaac Newton diſcovered the different refrangibility of the rays of light, he immediately applied his new theory of light and colours to the phenomena of the rainbow, taking this remarkable object of philoſophical inquiry where De Dominis and Deſcartes, for want of this knowledge, were obliged to leave their inveſtigations imperfect. For they could give no good reaſon why the bow ſhould be coloured, and much leſs could they give any ſatisfactory account of the order in which the colours appear.

204 The true cauſe of the colours of the rainbow.

Plate CCCLX.

If different particles of light had not different degrees of refrangibility, on which the colours depend, the rainbow, beſides being much narrower than it is, would be colourleſs; but the different refrangibility of differently coloured rays being admitted, the reaſon is obvious, both why the bow ſhould be coloured, and alſo why the colours ſhould appear in the order in which they are obſerved. Let *a* (fig. 8.) be a drop of water, and S a pencil of light; which, on its leaving the drop of water, reaches the eye of the ſpectator. This ray, at its entrance into the drop, begins to be decompoſed into its proper colours; and upon leaving the drop, after one reflection and a ſecond refraction, it is farther decompoſed into as many ſmall differently-coloured pencils as there are primitive colours in the light. Three of them only are drawn in this figure, of which the blue is the moſt, and the red the leaſt, refracted.

The doctrine of the different refrangibility of light enables us to give a reaſon for the ſize of a bow of each particular colour. Newton, having found that the ſines of refraction of the moſt refrangible and leaſt refrangible rays, in paſſing from rain water into air, are in the proportion of 185 to 182, when the ſine of incidence is 138, calculated the ſize of the bow; and he found, that if the ſun was only a phyſical point, without ſenſible magnitude, the breadth of the inner bow would be 2 degrees; and if to this 30′ were added for the apparent diameter of the ſun, the whole breadth would be 2½ degrees. But as the outermoſt colours, eſpecially the violet, are extremely faint, the breadth of the bow will not in reality appear to exceed two degrees. He finds, by the ſame principles, that the breadth of the exterior bow, if it was everywhere equally vivid, would be 4° 20′. But in this caſe there is a greater deduction to be made, on account of the faintneſs of the light of the exterior bow; ſo that in fact, it will not appear to be more than 3 degrees broad.

The principal phenomena of the rainbow are all explained on Sir Iſaac Newton's principles in the following propoſitions.

When the rays of the ſun fall upon a drop of rain and enter into it, ſome of them, after one reflection and two refractions, may come to the eye of a ſpectator who has his back towards the ſun, and his face towards the drop.

205 Explanation of the phenomena of rainbow on the principles of Newton.

If XY (fig. 9.) is a drop of rain, and the ſun ſhines upon it in any lines *s f*, *s d*, *s a*, &c. moſt of the rays will enter into the drop; ſome few of them only will be reflected from the firſt ſurface; thoſe rays which are reflected from thence do not come under our preſent conſideration, becauſe they are never refracted at all. The greateſt part of the rays then enter the drop, and thoſe paſſing on to the ſecond ſurface, will moſt of them be tranſmitted through the drop; but neither do thoſe rays which are thus tranſmitted fall under our preſent conſideration, ſince they are not reflected. For the rays, which are deſcribed in the propoſition, are ſuch as are twice refracted and once reflected. However, at the ſecond ſurface, or hinder part of the drop, at *p g*, ſome few rays will be reflected, whilſt the reſt are tranſmitted; thoſe rays proceed in ſome ſuch lines as *n r*, *n q*: and coming out of the drop in the lines *r v*, *q t*, may fall upon the eye of a ſpectator, who is placed anywhere in thoſe lines, with his face towards the drop, and conſequently with his back towards the ſun, which is ſuppoſed to ſhine upon the drop in the lines *s f*, *s d*, *s a*, &c. Theſe rays are twice refracted and once reflected; they are refracted when they paſs out of the air into the drop; they are reflected from the ſecond ſurface, and are refracted again when they paſs out of the drop into the air.

When rays of light reflected from a drop of rain come to the eye, thoſe are called effectual which are able to excite a ſenſation.

When rays of light come out of a drop of rain, they will not be effectual, unleſs they are parallel and contiguous.

There are but few rays that can come to the eye at all: for ſince the greateſt part of thoſe rays which enter the drop XY (fig. 9.) between X and *a*, paſs out of the drop through the hinder ſurface *p g*; only few are reflected from thence, and come out through the nearer ſurface between *a* and *y*. Now, ſuch rays as emerge, or come out of the drop, between *a* and Y, will be ineffectual, unleſs they are parallel to one another, as *r v* and *q t* are; becauſe ſuch rays as come out diverging from one another will be ſo far aſunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be ſufficient to excite any ſenſation. But even rays, which are parallel, as rv, qt, will not be effectual, unleſs there are ſeveral of them contiguous or very near to one another. The two rays rv and qt alone will not be perceived, though both of them enter the eye; for ſo very few rays are not ſufficient to excite a ſenſation.

When rays of light come out of a drop of rain after one reflection, thoſe will be effectual which are reflected from the ſame point, and which entered the drop near to one another.

Plate CCCLX.

Any rays, as sb and cd, (fig. 10.) when they have paſſed out of the air into a drop of water, will be refracted towards the perpendiculars bl, dl; and as the ray sb falls farther from the axis av than the ray cd, sb will be more refracted than cd; ſo that theſe rays, though parallel to one another at their incidence, may deſcribe the lines be and de after refraction, and be both of them reflected from one and the ſame point e. Now all rays, which are thus reflected from one and the ſame point, when they have deſcribed the lines ef, eg, and after reflection emerge at f and g, will be ſo refracted, when they paſs out of the drop into the air, as to deſcribe the lines fh, gi, parallel to one another. If theſe rays were to return from e in the lines eb, ed, and were to emerge at b and d, they would be refracted into the lines of their incidence bs, dc. But if theſe rays, inſtead of being returned in the lines eb, ed, are reflected from the ſame point e in the lines eg, ef, the lines of reflection eg and ef will be inclined both to one another and to the ſurface of the drop: juſt as much as the lines eb and ed are. Firſt, eb and eg make juſt the ſame angle with the ſurface of the drop: for the angle bex, which eb makes with the ſurface of the drop, is the complement of incidence, and the angle gev, which eg makes with the ſurface, is the complement of reflection; and theſe two are equal to one another. In the ſame manner we might prove, that ed and ef make equal angles with the ſurface of the drop. Secondly, The angle bed is equal to the angle feg; or the reflected rays eg, ef, and the incident rays be, de, are equally inclined to each other. For the angle of incidence bel is equal to the angle of reflection gel, and the angle of incidence del is equal to the angle of reflection fel; conſequently, the difference between the angles of incidence is equal to the difference between the angles of reflection, or $bel-del=gel-fel$, or $bed=gef$. Since therefore either the lines eg, ef, or the lines eb, ed, are equally inclined both to one another and to the ſurface of the drop; the rays will be refracted in the ſame manner, whether they were to return in the lines eb, ed, or are reflected in the lines eg, ef. But if they were to return in the lines eb, ed, the refraction, when they emerge at b and d would make them parallel. Therefore, if they are reflected from one and the ſame point e in the lines eg, ef, the refraction, when they emerge at g and f, will likewiſe make them parallel.

But though ſuch rays as are reflected from the ſame point in the hinder part of a drop of rain, are parallel to one another when they emerge, and ſo have one condition that is requiſite towards making them effectual, yet there is another condition neceſſary; for rays that are effectual, muſt be contiguous as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, thoſe only will be contiguous which enter it nearly at the ſame place.

Let XY (fig. 9.) be a drop of rain, ag the axis, or diameter of the drop, and sa a ray of light that comes from the ſun and enters the drop at the point a. This ray sa, becauſe it is perpendicular to both the ſurfaces, will paſs ſtraight through the drop in the line agh without being refracted; but any collateral rays, ſuch as thoſe that fall about sb, as they paſs through the drop, will be made to converge to their axis, and paſſing out at n will meet the axis at h: rays which fall farther from the axis than sb, ſuch as thoſe which fall about sc, will likewiſe be made to converge; but then their focus will be nearer to the drop than h. Suppoſe therefore i to be the focus to which the rays that fall about sc will converge, any ray sc, when it has deſcribed the line co within the drop, and is tending to the focus i, will paſs out of the drop at the point o. The rays that fall upon the drop about sd, more remote ſtill from the axis, will converge to a focus ſtill nearer than i, as ſuppoſe at k. Theſe rays therefore go out of the drop at p. The rays, that fall ſtill more remote from the axis, as se, will converge to a focus nearer than k, as ſuppoſe at l; and the ray se, when it has deſcribed the line eo within the drop, and is tending to l, will paſs out at the point o. The rays that fall ſtill more remote from the axis will converge to a focus ſtill nearer. Thus the ray sf will after refraction converge to a focus at m, which is nearer than l; and having deſcribed the line fn within the drop, it will paſs out to the point n. Now here we may obſerve, that as any rays sb or sc, fall farther above the axis sa, the points n, or o, where they paſs out behind the drop, will be farther above g; or that, as the incident ray riſes from the axis sa, the arc gno increaſes, till we come to ſome ray sd, which paſſes out of the drop at p; and this is the higheſt point where any ray that falls upon the quadrant or quarter ax can paſs out: for any rays se, or sf, that fall higher than sd, will not paſs out on any point above p, but at the points o, or n, which are below it. Conſequently, though the arc $gnop$ increaſes, whilſt the diſtance of the incident ray from the axis sa increaſes, till we come to the ray sd; yet afterwards, the higher the ray falls above the axis sa, this arc $pong$ will decreaſe.

We have hitherto ſpoken of the points on the hinder part of the drop, where the rays paſs out of it; but this was for the ſake of determining the points from whence thoſe rays are reflected, which do not paſs out behind the drop. For, in explaining the rainbow, we have no farther reaſon to conſider thoſe rays which go through the drop; ſince they can never come to the eye of a ſpectator placed anywhere in the lines rv or qt with his face towards the drop. Now, as there are many rays which paſs out of the drop between g and p, ſo ſome few rays will be reflected from thence: and conſequently the ſeveral points between g and p, which are the points where ſome of the rays paſs out of the drop, are likewiſe the points of reflection for the reſt which do not paſs out. Therefore, in reſpect of thoſe rays which are reflected we may call gp the arc of reflection; and may ſay, that this arc of reflection increaſes, as the diſtance of the incident ray from the axis *s a* increaſes, till we come to the ray *s d*; the arc of reflection is *g n* for the ray *s b*, it is *g o* for the ray *s c*, and *g p* for the ray *s d*. But after this, as the diſtance of the incident ray from the axis *s a* increaſes, the arc of reflection decreaſes; for *o g* leſs than *p g* is the arc of reflection for the ray *s e*, and *n g* is the arc of reflection for the ray *s f*.

From hence it is obvious, that ſome one ray, which falls above *s d*, may be reflected from the ſame point with ſome other ray which falls below *s d*. Thus, for inſtance, the ray *s b* will be reflected from the point *n*, and the ray *s f* will be reflected from the ſame point; and conſequently, when the reflected rays *n r*, *n q*, are refracted as they paſs out of the drop at *r* and *q*, they will be parallel, by what has been ſhown in the former part of this propoſition. But ſince the intermediate rays, which enter the drop between *s f* and *s b*, are not reflected from the ſame point *n*, theſe two rays alone will be the parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And conſequently theſe rays *r v*, *q t*, though they are parallel after they emerge at *r* and *q*, will not be contiguous, and for that reaſon will not be effectual; the ray *s d* is reflected from *p*, which has been ſhown to be the limit of the arc of reflection; ſuch rays as fall juſt above *s d*, and juſt below *s d*, will be reflected from nearly the ſame point *p*, as appears from what has been already ſhown. Theſe rays therefore will be parallel, becauſe they are reflected from the ſame point *p*; and they will likewiſe be contiguous, becauſe they all of them enter the drop at one and the ſame place very near to *d*. Conſequently, ſuch rays as enter the drop at *d*, and are reflected from *p* the limit of the arc of reflection, will be effectual; ſince, when they emerge at the fore part of the drop between *a* and *y*, they will be both parallel and contiguous.

If we can make out hereafter that the rainbow is produced by the rays of the ſun which are thus reflected from drops of rain as they fall whilſt the ſun ſhines upon them, this propoſition may ſerve to ſhow us, that this appearance is not produced by *any* rays that fall upon *any part*, and are reflected from any part of thoſe drops: ſince this appearance cannot be produced by any rays but thoſe which are effectual; and effectual rays muſt always enter each drop at one certain place in the fore part of it, and muſt likewiſe be reflected from one certain place in the hinder ſurface.

When rays that are effectual emerge from a drop of rain after one reflection and two refractions, thoſe which are moſt refrangible will, at their emerſion, make a leſs angle with the incident rays than thoſe do which are leaſt refrangible; and by this means the rays of different colours will be ſeparated from one another.

Plate CCCLX. Let *f h* and *g i* (fig. 10.) be effectual violet rays emerging from the drop at *f g*; and *f n*, *g p*, effectual red rays emerging from the ſame drop at the ſame place. Now, though all the violet rays are parallel to one another, becauſe they are ſuppoſed effectual, and though all the red rays are likewiſe parallel to one another for the ſame reaſon; yet the violet rays will not be parallel to the red rays. Theſe rays, as they have different colours, and different degrees of refrangibility, will diverge from one another; any violet ray *g i*, which emerges at *g*, will diverge from any red ray *g p*, which emerges at the ſame place. Now, both the violet ray *g i*, and the red ray *g p*, as they paſs out of the drop of water into the air, will be refracted from the perpendicular *l o*. But the violet ray is more refrangible than the red one; and for that reaſon *g i*, or the refracted violet ray, will make a greater angle with the perpendicular than *g p* the refracted red ray; or the angle *i g o* will be greater than the angle *p g o*. Suppoſe the incident ray *s b* to be continued in the direction *s k*, and the violet ray *i g* to be continued backward in the direction *i k*, till it meets the incident ray at *k*. Suppoſe likewiſe the red ray *p g* to be continued backwards in the ſame manner, till it meets the incident ray at *w*. The angle *i k s* is that which the violet ray, or moſt refrangible ray at its emerſion, makes with the incident ray; and the angle *p w s* is that which the red ray, or leaſt refrangible ray at its emerſion, makes with the incident ray. The angle *i k s* is leſs than the angle *p w s*. For, in the triangle, *g w k*, *g w s*, or *p w s*, is the external angle at the baſe, and *g k w* or *i k s* is one of the internal oppoſite angles; and either internal oppoſite angle is leſs than the external angle at the baſe. (Euc. B. I. Prop. 16.) What has been ſhown to be true of the rays *g i* and *g p* might be ſhown in the ſame manner of the rays *f h* and *f n*, or of any other rays that emerge reſpectively parallel to *g i* and *g p*. But all the effectual violet rays are parallel to *g i*, and all the effectual red rays are parallel to *g p*. Therefore the effectual violet rays at their emerſion make a leſs angle with the incident ones than the effectual red ones. And for the ſame reaſon, in all the other ſorts of rays, thoſe which are moſt refrangible, at their emerſion from a drop of rain after one reflection, will make a leſs angle with the incident rays, than thoſe do which are leſs refrangible.

Or otherwiſe: When the rays *g i* and *g p* emerge at the ſame point *g*, as they both come out of water into air, and conſequently are refracted from the perpendicular, inſtead of going ſtraight forwards in the line *e g* continued, they will both be turned round upon the point *g* from the perpendicular *g o*. Now it is eaſy to conceive, that either of theſe lines might be turned in this manner upon the point *g* as upon a centre, till they became parallel to *s b* the incident ray. But if either of theſe lines or rays were refracted ſo much from *g o* as to become parallel to *s b*, the ray ſo much refracted, would, after emerſion, make no angle with *s k*, becauſe it would be parallel to it. And conſequently that ray which is moſt turned round upon the point *g*, or that ray which is moſt refrangible, will after emerſion be neareſt parallel to the incident ray, or will make the leaſt angle with it. The ſame may be proved of all other rays emerging parallel to *g i* and *g p* reſpectively, or of all effectual rays; thoſe which are moſt refrangible will after emerſion make a leſs angle with the incident rays, than thoſe do which are leaſt refrangible.

But ſince the effectual rays of different colours make different angles with *s k* at their emerſion, they will be ſeparated from one another: ſo that if the eye was placed in the beam *f g h i*, it would receive only rays of one colour from the drop *x a g v*; and if it was placed in the beam $fgnp$, it would receive only rays of ſome other colour.

The angle swp, which the leaſt refrangible or red rays make with the incident ones when they emerge ſo as to be effectual, is found by calculation to be 42 degrees 2 minutes. And the angle ski, which the moſt refrangible rays make with the incident ones when they emerge ſo as to be effectual, is found to be 40 degrees 17 minutes. The rays which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between 42 degrees 2 minutes, and 40 degrees 17 minutes.

If a line is ſuppoſed to be drawn from the centre of the ſun through the eye of the ſpectator, the angle which any effectual ray, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.

Plate CCCLX.

Let the eye of the ſpectator be at i, (fig. 10.) and let gt be the line ſuppoſed to be drawn from the centre of the ſun through the eye of the ſpectator; the angle git, which any effectual ray makes with this line, will be equal to the angle iks, which the ſame ray makes with the incident ray sb or sk. If sb is a ray coming from the centre of the ſun, then ſince gt is ſuppoſed to be drawn from the ſame point, theſe two lines, upon account of the remoteneſs of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line ki croſſing theſe two parallel lines will make the alternate angles equal. (Euc. B. I. Prop. 29.) Therefore kit or git is equal to ski.

When the ſun ſhines upon the drops of rain as they are falling, the rays that come from thoſe drops to the eye of a ſpectator, after one reflection and two refractions, produce the primary rainbow.

206
Two rainbows ſeen at once.

If the ſun ſhines upon the rain as it falls, there are commonly ſeen two bows, as AFB, CHD, (fig. 11.); or if the cloud and rain does not reach over that whole ſide of the ſky where the bows appear, then only a part of one or of both bows is ſeen in that place where the rain falls. Of theſe two bows, the innermoſt AFB is the more vivid of the two, and this is called the *primary bow*. The outer part TFY of the primary bow is red, the inner part VEX is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppoſe the ſpectator's eye to be at O, and let LOP be an imaginary line drawn from the centre of the ſun through the eye of the ſpectator: if a beam of light S coming from the ſun falls upon any drop F; and the rays that emerge at F in the line FO, ſo as to be effectual, make an angle FOP of 42° 2′ with the line LP; then theſe effectual rays make an angle of 42° 2′ with the incident rays, by the preceding propoſition, and conſequently theſe rays will be red, ſo that the drop F will appear red. All the other rays, which emerge at F, and would be effectual if they fell upon the eye, are refracted more than the red ones, and conſequently will paſs above the eye. If a beam of light S falls upon the drop E; and the rays that emerge at E in the line EO, ſo as to be effectual, make an angle EOP of 40° 17′ with the line LP; then theſe effectual rays make likewiſe an angle of 40° 17′ with the incident rays, and the drop E will appear of a violet colour. All the other rays, which emerge at E, and would be effectual if they came to the eye, are refracted leſs than the violet ones, and therefore paſs below the eye. The intermediate drops between F and E will for the ſame reaſons be of the intermediate colours.

Thus we have ſhown why a ſet of drops from F to E, as they are falling, ſhould appear of the primary colours, red, orange, yellow, green, blue, indigo, and violet. It is not neceſſary that the ſeveral drops, which produce theſe colours, ſhould all of them fall at exactly the ſame diſtance from the eye. The angle FOP, for inſtance, is the ſame whether the diſtance of the drop from the eye is OF, or whether it is in any other part of the line OF ſomething nearer to the eye. And whilſt the angle FOP is the ſame, the angle made by the emerging and incident rays, and conſequently the colour of the drop, will be the ſame. This is equally true of any other drop. So that although in the figure the drops F and E are repreſented as falling perpendicularly one under the other, yet this is not neceſſary in order to produce the bow.

But the coloured line FE, which we have already accounted for, is only the breadth of the bow. It ſtill remains to be ſhown, why not only the drop F ſhould appear red, but why all the other drops quite from A to B in the arc ATFYB ſhould appear of the ſame colour. Now it is evident, that wherever a drop of rain is placed, if the angle which the effectual rays make with the line LP is equal to the angle FOP, that is, if the angle which the effectual rays make with the incident rays is 42° 2′, any of thoſe drops will be red, for the ſame reaſon that the drop F is of this colour.

If FOP was to turn round upon the line OP, ſo that one end of this line ſhould always be at the eye, and the other be at P oppoſite to the ſun; ſuch a motion of this figure would be like that of a pair of compaſſes turning round upon one of the legs OP with the opening FOP. In this revolution the drop F would deſcribe a circle, P would be the centre, and ATFYB would be an arc in this circle. Now ſince, in this motion of the line and drop OF, the angle made by FO with OP, that is the angle FOP, continues the ſame; if the ſun was to ſhine upon this drop as it revolves, the effectual rays would make the ſame angle with the incident rays, in whatever part of the arc ATFYB the drop was to be. Therefore, whether the drop is at A, or at T, or at Y, or at B, or wherever elſe it is in this whole arc, it would appear red, as it does at F.—The drops of rain, as they fall, are not indeed turned round in this manner: but then, as innumerable of them are falling at once in right lines from the cloud, whilſt one drop is at F, there will be others at Y, at T, at B, at A, and in every other part of the arc ATFYB: and all theſe drops will be red for the ſame reaſon that the drop F would have been red, if it had been in the ſame place. Therefore, when the ſun ſhines upon the rain as it falls, there will be a red arc ATFYB oppoſite to the ſun. In the ſame manner, becauſe the drop E is violet, we might prove that any other drop, which, whilſt it is falling, is in any part of the arc AVEXB, will be violet; and conſequently, at the ſame time that the red arc ATFYB appears, there will likewiſe be a violet arc AVEXB below or within it. FE is the diſtance between theſe two coloured arcs; and from what has been ſaid, it follows, that the intermediate ſpace between theſe two arcs will be filled up with arcs of the intermediate colours, orange, yellow, blue, green, and indigo. All theſe coloured arcs together make up the primary rainbow.

The primary rainbow is never a greater arc than a ſemicircle.

Plate CCCLX.

207
Why the arc of the primary rainbow is never greater than a ſemicircle.

Since the line LOP is drawn from the ſun through the eye of the ſpectator, and ſince P (fig. 9.) is the centre of the rainbow; it follows, that the centre of the rainbow is always oppoſite to the ſun. The angle FOP is an angle of 42° 2′, as was obſerved, or F the higheſt part of the bow is 42° 2′ from P the centre of it. If the ſun is more than 42° 2′ high, P the centre of the rainbow, which is oppoſite to the ſun, will be more than 42° 2′ below the horizon; and conſequently F the top of the bow, which is only 42° 2′ from P, will be below the horizon; that is, when the ſun is more than 42° 2′ high, no primary rainbow will be ſeen. If the ſun is ſomething leſs than 42° 2′ high, then P will be ſomething leſs than 42° 2′ below the horizon; and conſequently F, which is only 42° 2′ from P, will be juſt above the horizon; that is, a ſmall part of the bow at this height of the ſun will appear cloſe to the ground oppoſite to the ſun. If the ſun is 20° high, then P will be 20° below the horizon; and F the top of the bow, being 42° 2′ from P, will be 22° 2′ above the horizon; therefore, at this height of the ſun, the bow will be an arc of a circle whoſe centre is below the horizon; and conſequently that arc of the circle which is above the horizon, or [illegible] bow, will be leſs than a ſemicircle. If the ſun is in the horizon, then P, the centre of the bow, will be in the oppoſite part of the horizon; F, the top of the bow, will be 42° 2′ above the horizon; and the bow itſelf, becauſe the horizon paſſes through the centre of it, will be a ſemicircle. More than a ſemicircle can never appear; becauſe if the bow was more than a ſemicircle, P the centre of it muſt be above the horizon; but P is always oppoſite to the ſun, therefore P cannot be above the horizon, unleſs the ſun is below it; and when the ſun is ſet, or is below the horizon, it cannot ſhine upon the drops of rain as they fall; and conſequently, when the ſun is below the horizon, no bow at all can be ſeen.

When the rays of the ſun fall upon a drop of rain, ſome of them, after two reflections and two refractions, may come to the eye of a ſpectator, who has his back towards the ſun and his face towards the drop.

If HGW (fig. 12.) is a drop of rain, and parallel rays coming from the ſun, as zv, yw, fall upon the lower part of it, they will be refracted towards the perpendiculars vl, wl, as they enter into it, and will deſcribe ſome ſuch lines as vh, wi. At h and i great part of theſe rays will paſs out of the drop; but ſome of them will be reflected from thence in the lines hf, ig. At f and g again, great part of the rays that were reflected thither will paſs out of the drop. But theſe rays will not come to the eye of a ſpectator at o. However, here again all the rays will not paſs out; but ſome few will be reflected from f and g, in ſome ſuch lines as fd, gb; and theſe, when they emerge out of the drop of water into the air at b and d, will be refracted from the perpendiculars, and, deſcribing the lines dt, bo, may come to the eye of the ſpectator who has his back towards the ſun and his face towards the drop.

Theſe rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effectual when they emerge after two refractions and two reflections.

No rays can be effectual, unleſs they are contiguous and parallel. From what was ſaid, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they muſt enter the drop nearly at one and the ſame place. And if ſuch rays as are contiguous are parallel after the firſt reflection, they will emerge parallel, and therefore will be effectual. Let zv and yw be contiguous rays which come from the ſun, and are parallel to one another when they fall upon the lower part of the drop, ſuppoſe theſe rays to be refracted at v and w, and to be reflected at b and i; if they are parallel to one another, as bf, gi, after this firſt reflection, then, after they are reflected a ſecond time from f and g, and refracted a ſecond time as they emerge at d and b, they will go out of the drop parallel to one another in the lines dt and bo, and will therefore be effectual.

The rays zv, yw, are refracted towards the perpendiculars vl, wl, when they enter the drop, and will be made to converge. As theſe rays are very oblique, their focus will not be far from the ſurface vw. If this focus is at k, the rays, after they have paſſed the focus, will diverge from thence in the directions kb, ki; and if ki is the principal focal diſtance of the concave reflecting ſurface bi, the reflected rays bf, ig, will be parallel. Theſe rays ef, ig, are reflected again from the concave ſurface fg, and will meet in a focus at e, ſo that ge will be the principal focal diſtance of this reflecting ſurface fg. And becauſe bi and fg are parts of the ſame ſphere, the principal focal diſtances ge and ki will be equal to one another. When the rays have paſſed the focus e, they will diverge from thence in the lines ed, eb: and we are to ſhow, that when they emerge at d and b, and are refracted there, they will become parallel.

Now if the rays vk, wk, when they have met at k, were to be turned back again in the directions kv, kw, and were to emerge at v and w, they would be refracted into the lines of their incidence, vz, wy, and therefore would be parallel. But ſince ge is equal to ik, as has already been ſhown, the rays ed, eb, that diverge from e, fall in the ſame manner upon the drop at d and b, as the rays kv, kw, would fall upon it at v and w; and ed, eb, are juſt as much inclined to the refracting ſurface db, as kv, kw, would be to the ſurface vw. From hence it follows, that the rays ed, eb, emerging at d and b, will be refracted in the ſame manner, and will have the ſame direction in reſpect of one another, as kv, kw, would have. But kv and kw would be parallel after refraction. Therefore ed and eb will emerge in lines dp, bo, ſo as to be parallel to one another, and conſequently ſo as to be effectual.

When rays that are effectual emerge from a drop of rain after two reflections and two refractions, thoſe which are moſt refrangible will at their emerſion make a greater angle with the incident rays than thoſe do which are leaſt refrangible; and by this means the rays of different colours will be ſeparated from one another.

Plate CCCLX.

If rays of different colours, which are differently refrangible, emerge at any point *b* (fig. 12.), theſe rays will not be all of them equally refracted from the perpendicular. Thus, if *b o* is a red ray, which is of all others the leaſt refrangible, and *b m* is a violet ray, which is of all others the moſt refrangible; when theſe two rays emerge at *b*, the violet ray will be refracted more from the perpendicular *b x* than the red ray, and the refracted angle *x b m* will be greater than the refracted angle *x b o*. From hence it follows, that theſe two rays, after emerſion, will diverge from one another. In like manner, the rays that emerge at *d* will diverge from one another; a red ray will emerge in the line *d p*, a violet ray in the line *d t*. So that though all the effectual red rays of the beam *b d m t* are parallel to one another, and all the effectual red rays of the beam *b d o p* are likewiſe parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be ſeparated from one another.

This will appear farther, if we conſider what the propoſition affirms, That any violet or moſt refrangible ray will make a greater angle with the incident rays, than any red or leaſt refrangible ray makes with the ſame incident rays. Thus if *y w* is an incident ray, *b m* a violet ray emerging from the point *b*, and *b o* a red ray emerging from the ſame point; the angle which the violet ray makes with the incident one is *y r m*, and that which the red ray makes with it is *y s o*. Now *y r m* is a greater angle than *y s o*. For in the triangle *b r s* the internal angle *b r s* is leſs than *b s y* the external angle at the baſe. (Eucl. B. I. Prop. 16.) But *y r m* is the complement of *b r s* or of *b r y* to two right ones, and *y s o* is the complement of *b s y* to two right ones. Therefore, ſince *b r y* is leſs than *b s y*, the complement of *b r y* to two right angles will be greater than the complement of *b s y* to two right angles; or *y r m* will be greater than *y s o*.

Or otherwiſe: Both the rays *b o* and *b m*, when they are refracted in paſſing out of the drop at *b*, are turned round upon the point *b* from the perpendicular *b x*. Now either of theſe lines *b o* or *b m* might be turned round in this manner, till it made a right angle with *y w*. Conſequently, that ray which is moſt turned round upon *b*, or which is moſt refracted, will make an angle with *y w*, that will be nearer to a right one than that ray makes with it which is leaſt rurned round upon *b*, or which is leaſt refracted. Therefore that ray which is moſt refracted will make a greater angle with the incident ray than that which is leaſt refracted.

But ſince the emerging rays, as they are differently refrangible, make different angles with the ſame incident ray *y w*, the refraction which they ſuffer at emerſion will ſeparate them from one another.

The angle *y r m*, which the moſt refrangible or violet rays make with the incident ones, is found by calculation to be 54° 7′; and the angle *y s o*, which the leaſt refrangible or red rays make with the incident ones, is found to be 50° 57′: the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between 54° 7′ and 50° 57′.

If a line is ſuppoſed to be drawn from the centre of the ſun through the eye of the ſpectator; the angle which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes with that line.

If *y w* (fig. 12.) is an incident ray, *b o* an effectual ray, and *q n* a line drawn from the centre of the ſun though *o* the eye of the ſpectator; the angle *y s o*, which the effectual ray makes with the incident ray, is equal to *s o n* the angle which the ſame effectual ray makes with the line *q n*. For *y w* and *q n*, conſidered as drawn from the centre of the ſun, are parallel; *b o* croſſes them, and conſequently makes the alternate angles *y s o*, *s o n*, equal to one another. Eucl. B. I Prop. 29.

When the ſun ſhines upon the drops of rain as they are falling, the rays that come from theſe drops to the eye of a ſpectator, after two reflections and two refractions, produce the ſecondary rainbow.

208 The ſecondary rainbow produced by two reflections and two refractions.

The ſecondary rainbow is the outermoſt, CHD, fig. 11. When the ſun ſhines upon a drop of rain H; and the rays HO, which emerge at H ſo as to be effectual, make an angle HOP of 54° 7′ with LOP a line drawn from the ſun through the eye of the ſpectator; the ſame effectual rays will make likewiſe an angle of 54° 7′ with the incident rays S, and the rays which emerge at this angle are violet ones, by what was obſerved above. Therefore, if the ſpectator's eye is at O, none but violet rays will enter it: for as all the other rays make a leſs angle with OP, they will fall above the ſpectator's eye. In like manner, if the effectual rays that emerge from the drop G make an angle of 50° 57′ with the line OP, they will likewiſe make the ſame angle with the incident rays S; and conſequently, from the drop G to the ſpectator's eye at O, no rays will come but red ones; for all the other rays making a greater angle with the line OP, will fall below the eye at O. For the ſame reaſon, the rays emerging from the intermediate drops between H and G, and coming to the ſpectator's eye at O, will emerge at intermediate angles, and therefore will have the intermediate colours. Thus if there are ſeven drops from H to G incluſively, their colours will be violet, indigo, blue, green, yellow, orange, and red. This coloured line is the breadth of the ſecondary rainbow.

Now, if HOP was to turn round upon the line OP, like a pair of compaſſes upon one of the legs OP with the opening HOP, it is plain from the ſuppoſition, that, in ſuch a revolution of the drop H, the angle HOP would be the ſame, and conſequently the emerging rays would make the ſame angle with the incident ones. But in ſuch a revolution the drop would deſcribe a circle of which P would be the centre, and CNHRD an arc. Conſequently, ſince, when the drop is at N, or at R, or anywhere elſe in that arc, the emerging rays make the ſame angle with the incident ones as when the drop is at H, the colour of the drop

Of the Rainbow.

will be the ſame to an eye placed at O, whether the drop is at N, or at H, or at R, or anywhere elſe in that arc. Now though the drop does not thus turn round as it falls, and does not paſs through the ſeveral parts of this arc, yet, ſince there are drops of rain falling everywhere at the ſame time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and theſe drops will all of them be violet-coloured, for the ſame reaſon that the drop H would have been of this colour if it had been in any of thoſe places. In like manner, as the drop G is red when it is at G, it would likewiſe be red in any part of the arc CWGQD; and ſo will any other drop when, as it is falling, it comes to any part of that arc. Thus as the ſun ſhines upon the rain, whilſt it falls, there will be two arcs produced, a violet-coloured one CNHRD, and a red one CWGQD; and for the ſame reaſons the intermediate ſpace between theſe two arcs will be filled up with arcs of the intermediate colours. All theſe arcs together make up the ſecondary rainbow.

The colours of the ſecondary rainbow are fainter than thoſe of the primary rainbow; and are ranged in the contrary order.

209
Why the colours of the ſecondary rainbow are fainter than thoſe of the primary, and ranged in a contrary order.

The primary rainbow is produced by ſuch rays as have been only once reflected; the ſecondary rainbow is produced by ſuch rays as have been twice reflected. But at every reflection ſome rays paſs out of the drop of rain without being reflected; ſo that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the ſecondary bow are produced by fewer rays, and conſequently will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outſide of it, the colours are ranged in this order; red, orange, yellow, green, blue, indigo, violet. In the ſecondary bow, reckoning from the outſide, the colours are violet, indigo, blue, green, yellow, orange, red. So that the the red, which is the outermoſt or higheſt colour in the primary bow, is the innermoſt or loweſt colour in the ſecondary one.

Plate CCCLX.

Now the violet rays, when they emerge ſo as to be effectual after one reflection, make a leſs angle with the incident rays than the red ones; conſequently the violet rays make a leſs angle with the lines OP (fig. 11.) than the red ones. But, in the primary rainbow, the rays are only once reflected, and the angle which the effectual rays make with OP is the diſtance of the coloured drop from P the centre of the bow. Therefore the violet drops, or violet arc, in the primary bow, will be nearer to the centre of the bow than the red drops or red arc; that is, the innermoſt colour in the primary bow will be violet, and the outermoſt colour will be red. And, for the ſame reaſon, through the whole primary bow, every colour will be nearer to the centre P, as the rays of that colour are more refrangible.

But the violet rays, when they emerge ſo as to be effectual after two reflections, make a greater angle with the incident rays than the red ones; conſequently the violet rays will make a greater angle with the line OP, than the red ones. But in the ſecondary rainbow the rays are twice reflected, and the angle which effectual rays make with OP is the diſtance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the ſecondary bow will be farther from the centre of the bow, than the red drops or red arc; that is, the outermoſt colour in the ſecondary bow will be violet, and the innermoſt colour will be red. And, for the ſame reaſon, through the whole ſecondary bow, every colour will be further from the centre P, as the rays of that colour are more refrangible.

The apparent place &c. of objects.

§ 2. *Of Coronas, Parhelia, &c.*

Under the articles CORONA and PARHELION, a pretty full account is given of the different hypotheſes concerning theſe phenomena, and likewiſe of the method by which theſe hypotheſes are ſupported, from the known laws of refraction and reflection; to which therefore, in order to avoid repetition, we muſt refer.

§ 3. *Of the apparent Place, Diſtance, Magnitude, and Motion of Objects.*

210
Dr Barrow's theory reſpecting the apparent place of objects.

Philoſophers in general had taken for granted, that the place to which the eye refers any viſible object ſeen by reflection or refraction, is that in which the viſual ray meets a perpendicular from the object upon the reflecting or refracting plane. But this method of judging of the place of objects was called in queſtion by Dr Barrow, who contended that the arguments brought in favour of the opinion were not concluſive. Theſe arguments are, that the images of objects appear ſtraight in a plane mirror, but curved in a convex or concave one: that a ſtraight thread, when partly immerſed perpendicularly in water, does not appear crooked as when it is obliquely plunged into the fluid; but that which is within the water ſeems to be a continuation of that which is without. With reſpect to the reflected image, however, of a perpendicular right line from a convex or concave mirror, he ſays, that it is not eaſy for the eye to diſtinguiſh the curve that it really makes; and that, if the appearance of a perpendicular thread, part of which is plunged in water, be cloſely attended to, it will not favour the common hypotheſis. If the thread is of any ſhining metal, as ſilver, and viewed obliquely, the image of the part immerſed will appear to detach itſelf ſenſibly from that part which is without the water, ſo that it cannot be true that every object appears to be in the ſame place where the refracted ray meets the perpendicular; and the ſame obſervation, he thinks, may be extended to the caſe of reflection. According to this writer, we refer every point of an object to the place from which the pencils of light, that give us the image of it, iſſue, or from which they would have iſſued if no reflecting or refracting ſubſtance intervened. Purſuing this principle, he proceeds to inveſtigate the place in which the rays iſſuing from each of the points of an object, and which reach the eye after one reflection or refraction, meet; and he found, that the refracting ſurface was plane, and the refraction was made from a denſer medium into a rarer, thoſe rays would always meet in a place between the eye and a perpendicular to the point of incidence. If a convex miror be uſed, the caſe will be the ſame; but if the mirror be plane, the rays will meet in the perpendicular, and beyond it if it be concave.

The apparent place, &c. of objects.

cave. He alſo determined, according to theſe principles, what form the image of a right line will take, when it is preſented in different manners to a ſpherical mirror, or when it is ſeen through a refracting medium.

Probable as Dr Barrow thought the maxim which he endeavoured to eſtabliſh, concerning the ſuppoſed place of viſible objects, he has the candour to mention an objection to it, and to acknowledge that he was not able to give a ſatisfactory ſolution of it. It is this. Let an object be placed beyond the focus of a convex lens; and if the eye be cloſe to the lens, it will appear confuſed, but very near to is true place. If the eye be a little withdrawn, the confuſion will increaſe, and the object will ſeem to come nearer; and when the eye is near the focus, the confuſion will be exceedingly great, and the object will ſeem to be cloſe to the eye. But in this experiment the eye receives no rays but thoſe that are converging: and the point from which they iſſue is ſo far from being nearer than the object, that it is beyond it; notwithſtanding which, the object is conceived to be much nearer than it is, though no very diſtinct idea can be formed of its preciſe diſtance. It may be obſerved, that in reality, the rays falling upon the eye in this caſe in a manner quite different from that in which they fall upon it in other circumſtances, we can form no judgment about the place from which they iſſue. This ſubject was afterwards taken up by Berkeley, Smith, Montucla, and others.

211 M. de la Hire's obſervations

M. de la Hire made ſeveral valuable obſervations concerning the diſtance of viſible objects, and various other phenomena of viſion, which are well worth our notice. He alſo took particular pains to aſcertain the manner in which the eye conforms itſelf to the view of objects placed at different diſtances. He enumerates five circumſtances, which aſſiſt us in judging of the diſtance of objects, namely their apparent magnitude, the ſtrength of the colouring, the direction of the two eyes, the parallax of the objects, and the diſtinctneſs of their ſmall parts. Painters, he ſays, can only take advantage of the two firſt-mentioned circumſtances, and therefore pictures can never perfectly deceive the eye; but in the decorations of theatres, they, in ſome meaſure, make uſe of them all. The ſize of objects, and the ſtrength of their colouring, are diminiſhed in proportion to the diſtance at which they are intended to appear. Parts of the ſame object which are to appear at different diſtances, as columns in an order of architecture, are drawn upon different planes, a little removed from one another, that the two eyes may be obliged to change their direction, in order to diſtinguiſh the parts of the nearer plane from thoſe of the more remote. The ſmall diſtance of the planes ſerves to make a ſmall parallax, by changing the poſition of the eye; and as we do not preſerve a diſtinct idea of the quantity of parallax, correſponding to the different diſtances of objects, it is ſufficient that we perceive there is a parallax, to be convinced that theſe planes are diſtant from one another, without determining what that diſtance is; and as to the laſt circumſtance, viz. the diſtinctneſs of the ſmall parts of objects, it is of no uſe in diſcovering the deception, on account of the falſe light that is thrown upon theſe decorations.

To theſe obſervations concerning deceptions of ſight, we ſhall add a ſimilar one of M. le Cat, who took notice that the reaſon why we imagine objects to be larger when they are ſeen through a miſt, is the dimneſs or obſcurity with which they are then ſeen; this circumſtance being aſſociated with the idea of great diſtance. This, he ſays, is confirmed by our being ſurpriſed to find, upon approaching ſuch objects, that they are ſo much nearer to us, as well as ſo much ſmaller, than we had imagined.

The apparent place, &c. of objects.

212 M. le Cat's account of the largeneſs of objects in miſt.

Among other caſes concerning viſion, which fell under the conſideration of M. de la Hire, he mentions one which is of difficult ſolution. It is when a candle, in a dark place, and ſituated beyond the limits of diſtinct viſion, is viewed through a very narrow chink in a card; in which caſe a conſiderable number of candles, ſometimes ſo many as ſix, will be ſeen along the chink. This appearance he aſcribes to ſmall irregularities in the ſurface of the humours of the eye, the effect of which is not ſenſible when rays are admitted into the eye through the whole extent of the pupil, and conſequently one principal image effaces a number of ſmall ones; whereas, in this caſe, each of them is formed ſeparately, and no one of them is ſo conſiderable as to prevent the others from being perceived at the ſame time.

There are few perſons, M. de la Hire obſerves, who have both their eyes perfectly equal, not only with reſpect to the limits of diſtinct viſion, but alſo with reſpect to the colour with which objects appear tinged when they are viewed by them, eſpecially if one of the eyes has been expoſed to the impreſſion of a ſtrong light. To compare them together in this reſpect, he directs us to take two thin cards, and to make in each of them a round hole of a third or a fourth of a line in diameter, and, applying one of them to each of the eyes, to look through the holes on a white paper, equally illuminated, when a circle of the paper will appear to each of the eyes, and, placing the cards properly, theſe two circles may be made to touch one another, and thereby the appearance of the ſame object to each of the eyes may be compared to the greateſt advantage. To make this experiment with the greateſt exactneſs, it is neceſſary, he ſays, that the eyes be kept ſhut ſome time before the cards be applied to them.

M. de la Hire firſt endeavoured to explain the cauſe of thoſe dark ſpots which ſeem to float before the eyes, eſpecially thoſe of old people. They are moſt viſible when the eyes are turned towards an uniform white object, as the ſnow in the open fields. If they be fixed when the eye is ſo, this philoſopher ſuppoſed that they were occaſioned by extravaſated blood upon the retina. But he thought that the moveable ſpots were occaſioned by opaque matter floating in the aqueous humour of the eye. He thought the vitreous humour was not ſufficiently limpid for this purpoſe.

By the following calculation, M. de la Hire gives us an idea of the extreme ſenſibility of the optic nerves. One may ſee very eaſily, at the diſtance of 4000 toiſes, the ſail of a wind mill, 6 feet in diameter; and the eye being ſuppoſed to be an inch in diameter, the picture of this ſail, at the bottom of the eye, will be $\frac{1}{8000}$ of an inch, which is leſs than the 666th part of a line, and is about the 66th part of a common hair, or the 8th part of a ſingle thread of ſilk. So ſmall, therefore, muſt one of the fibres of the optic nerve be, which he ſays

OPTICS.

ſays is almoſt inconceivable, ſince each of theſe fibres is a tube that contains ſpirits. If birds perceive diſtant objects as well as men, which he thinks very probable, he obſerves that the fibres of their optic nerves muſt be much finer than ours.

213
Berkeley's account of the judgement formed concerning diſtance by confuſed viſion.

The perſon who firſt took much notice of Dr Barrow's hypotheſis was the ingenious Dr Berkeley, biſhop of Cloyne, who diſtinguiſhed himſelf ſo much by the objections which he ſtarted to the reality of a material world, and by his oppoſition to the Newtonian doctrine of fluxions. In his Eſſay towards a new Theory of Viſion, he obſerves, that the circle formed upon the retina, by the rays which do not come to a focus, produce the ſame confuſion in the eye, whether they croſs one another before they reach the retina, or tend to do it afterwards: and therefore that the judgment concerning diſtance will be the ſame in both the caſes, without any regard to the place from which the rays originally iſſued; ſo that in this caſe, as, by receding from the lens, the confuſion, which always accompanies the nearneſs of an object, increaſes, the mind will judge that the object comes nearer.

214
Smith's account.

But, ſays Dr Smith, if this be true, the object ought always to appear at a leſs diſtance from the eye than that at which objects are ſeen diſtinctly, which is not the caſe: and to explain this appearance, as well as every other in which a judgment is formed concerning diſtance, he maintains, that we judge of it by the apparent magnitude of objects only, or chiefly; ſo that, ſince the image grows larger as we recede from the lens through which it is viewed, we conceive the object to come nearer. He alſo endeavours to ſhow, that, in all caſes in which glaſſes are uſed, we judge of diſtance by the ſame ſimple rule; from which he concludes univerſally, that the apparent diſtance of an object ſeen in a glaſs is to its apparent diſtance ſeen by the naked eye, as the apparent magnitude to the naked eye is to its apparent magnitude in the glaſs.

215
Objected to by Mr Robins.

But that we do not judge of diſtance merely by the angle under which objects are ſeen, is an obſervation as old as Alhazen, who mentions ſeveral inſtances, in which, though the angles under which objects appear to be different, the magnitudes are univerſally and inſtantaneouſly deemed not to be ſo. And Mr Robins clearly ſhows the hypotheſis of Dr Smith to be contrary to fact in the moſt common and ſimple caſes. In microſcopes, he ſays, it is impoſſible that the eye ſhould judge the object to be nearer than the diſtance at which it has viewed the object itſelf, in proportion to the degree of magnifying. For when the microſcope magnifies much, this rule would place the image at a diſtance, of which the ſight cannot poſſibly form any opinion, as being an interval from the eye at which no object can be ſeen. In general, he ſays, he believes, that whoever looks at an object through a convex glaſs, and then at the object itſelf without the glaſs, will find it to appear nearer in the latter caſe, though it be magnified in the glaſs; and in the ſame trial with the concave glaſs, though by the glaſs the object be diminiſhed, it will appear nearer through the glaſs than without it.

But the moſt convincing proof that the apparent diſtance of the image is not determined by its apparent magnitude, is the following experiment. If a double convex glaſs be held upright before ſome luminous object, as a candle, there will be ſeen two images, one erect, and the other inverted. The firſt is made ſimply by reflection from the neareſt ſurface, the ſecond by reflection from the farther ſurface, the rays undergoing a refraction from the firſt ſurface both before and after the reflection. If this glaſs has not too ſhort a focal diſtance when it is held near the object, the inverted image will appear larger than the other, and alſo nearer; but if the glaſs be carried off from the object, though the eye remain as near to it as before, the inverted image will diminiſh ſo much faſter than the other, that, at length, it will appear very much leſs than it, but ſtill nearer. Here, ſays Mr Robins, two images of the ſame ſubject are ſeen under one view, and their apparent diſtances immediately compared; and here it is evident, that thoſe diſtances have no neceſſary connexion with the apparent magnitude. He alſo ſhows how this experiment may be made ſtill more convincing, by ſticking a piece of paper on the middle of the lens, and viewing it through a ſhort tube.

216
M. Bouguer adopts Dr Barrow's maxim.

M. Bouguer adopts the general maxim of Dr Barrow, in ſuppoſing that we refer objects to the place from which the pencils of rays ſeemingly converge at their entrance into the pupil. But when rays iſſue from below the ſurface of a veſſel of water, or any other refracting medium, he finds that there are always two different places of this ſeeming convergence; one of them of the rays that iſſue from it in the ſame vertical circle, and therefore fall with different degrees of obliquity upon the ſurface of the refracting medium; and another, of thoſe that fall upon the ſurface with the ſame degree of obliquity, entering the eye laterally with reſpect to one another. Sometimes, he ſays, one of theſe images is attended to by the mind, and ſometimes the other, and different images may be obſerved by different perſons. An object plunged in water affords an example, he ſays, of this duplicity of images.

Plate CCCLXI.

If BA b (fig. 1.) be part of the ſurface of water, and the object be at O, there will be two images of it in two different places; one at G, on the cauſtic by refraction, and the other at E, in the perpendicular AO, which is as much a cauſtic as the other line. The former image is viſible by the rays ODM, O d m, which are one higher than the other, in their progreſs to the eye; whereas the image at E is made by the rays ODM, O r f, which enter the eye laterally. This, ſays he, may ſerve to explain the difficulty of Father Tacquet, Barrow, Smith, and many other authors, and which Newton himſelf conſidered as a very difficult problem, though it might not be abſolutely inſoluble.

G. W. Kraft has ably ſupported the opinion of Dr Barrow, that the place of any point, ſeen by reflection from the ſurface of any medium, is that in which rays iſſuing from it, infinitely near to one another, would meet; and conſidering the caſe of a diſtant object, viewed in a concave mirror, by an eye very near to it, when the image, according to Euclid and other writers would be between the eye and the object, and the rule of Dr Barrow cannot be applied; he ſays that in this caſe the ſpeculum may be conſidered as a plane, the effect being the ſame, only the image is more obſcure.

Dr Porterfield gives a diſtinct and comprehenſive view of the natural methods of judging concerning the diſtance of objects.

217
Dr Porterfield's view of the ſubject.

The conformation of the eye, he obſerves, can be of no uſe to us with reſpect to objects that are placed without the limits of diſtinct viſion. As the object, however, does then appear more or leſs confuſed, according as it is more or leſs removed from thoſe limits, this confuſion aſſiſts the mind in judging of the diſtance of the object; it being always eſteemed ſo much the nearer, or the farther off, by how much the confuſion is greater. But this confuſion hath its limits alſo beyond which it can never extend; for when an object is placed at a certain diſtance from the eye, to which the breadth of the pupil bears no ſenſible proportion, the rays of light that come from a point in the object, and paſs the pupil, are ſo little diverging, that they may be conſidered as parallel. For a picture on the retina will not be ſenſibly more confuſed, though the object be removed to a much greater diſtance.

The moſt univerſal, and frequently the moſt ſure means of judging of the diſtance of objects is, he ſays, the angle made by the optic axis. For our two eyes are like two different ſtations, by the aſſiſtance of which diſtances are taken; and this is the reaſon why thoſe perſons who are blind of one eye, ſo frequently miſs their marks in pouring liquor into a glaſs, ſnuffing a candle, and ſuch other actions as require that the diſtance be exactly diſtinguiſhed. To convince ourſelves of the uſefulneſs of this method of judging of the diſtance of objects, he directs us to ſuſpend a ring in a thread, ſo that its ſide may be towards us, and the hole in it to the right and left hand; and taking a ſmall rod, crooked at the end, retire from the ring two or three paces, and having with one hand covered one of our eyes, to endeavour with the other to paſs the crooked end of the rod through the ring. This, ſays he, appears very eaſy; and yet, upon trial, perhaps once in 100 times we ſhall not ſucceed, eſpecially if we move the rod a little quickly.

Our author obſerves, that by perſons recollecting the time when they began to be ſubject to the miſtakes above-mentioned, they may tell when it was that they loſt the uſe of one of their eyes; which many perſons are long ignorant of, and which may be a circumſtance of ſome conſequence to a phyſician †. The uſe of this ſecond method of judging of diſtances Dechales limited to 120 feet; beyond which, he ſays, we are not ſenſible of any difference in the angle of the optic axis.

† See *Medicine*, Nº 360.

A third method of judging of the diſtance of objects, conſiſts in their apparent magnitudes, on which ſo much ſtreſs was laid by Dr Smith. From this change in the magnitude of the image upon the retina, we eaſily judge of the diſtance of objects, as often as we are otherwiſe acquainted with the magnitude of the objects themſelves; but as often as we are ignorant of the real magnitude of bodies, we can never, from their apparent magnitude, form any judgment of their diſtance.

From this we may ſee why we are ſo frequently deceived in our eſtimates of diſtance, by any extraordinary magnitudes of objects ſeen at the end of it; as, in travelling towards a large city, or a caſtle, or a cathedral church, or a mountain larger than ordinary, we fancy them to be nearer than we find them to be. This alſo is the reaſon why animals, and all ſmall objects, ſeen in valleys, contiguous to large mountains, appear exceedingly ſmall. For we think the mountain nearer to us than if it were ſmaller; and we ſhould not be ſurpriſed at the ſmallneſs of the neighbouring animals, if we thought them farther off. For the ſame reaſon, we think them exceedingly ſmall, when they are placed upon the top of a mountain, or a large building; which appear nearer to us than they really are, on account of their extraordinary ſize.

218
Why objects ſeen from a high building appear ſmaller than they are.

Dr Jurin clearly accounts for our imagining objects, when ſeen from a high building, to be ſmaller than they are, and ſmaller than we fancy them to be when we view them at the ſame diſtance on level ground. It is, ſays he, becauſe we have no diſtinct idea of diſtance in that direction, and therefore judge of things by their pictures upon the eye only; but cuſtom will enable us to judge rightly even in this caſe.

Let a boy, ſays he, who has never been upon any high building, go to the top of the monument, and look down into the ſtreet; the objects ſeen there, as men and horſes, will appear ſo ſmall as greatly to ſurpriſe him. But 10 or 20 years after, if in the mean time he has uſed himſelf now and then to look down from that and other great heights, he will no longer find the ſame objects to appear ſo ſmall. And if he was to view the ſame objects from ſuch heights as frequently as he ſees them upon the ſame level with himſelf in the ſtreets, he ſuppoſes that they would appear to him juſt of the ſame magnitude from the top of the monument, as they do from a window one ſtory high. For this reaſon it is, that ſtatues placed upon very high buildings ought to be made of a larger ſize than thoſe which are ſeen at a nearer diſtance; becauſe all perſons, except architects, are apt to imagine the height of ſuch buildings to be much leſs than it really is.

The fourth method by which Dr Porterfield ſays that we judge of the diſtance of objects, is the force with which their colour ſtrikes upon our eyes. For if we be aſſured that two objects are of a ſimilar and like colour, and that one appears more bright and lively than the other, we judge that the brighter object is the nearer of the two.

The fifth method conſiſts in the different appearance of the ſmall parts of objects. When theſe parts appear diſtinct, we judge that the object is near; but when they appear confuſed, or when they do not appear at all, we judge that it is at a greater diſtance. For the image of any object, or part of an object, diminiſhes as the diſtance of it increaſes.

The ſixth and laſt method by which we judge of the diſtance of objects is, that the eye does not repreſent to our mind one object alone, but at the ſame time all thoſe that are placed betwixt us and the principal object, whoſe diſtance we are conſidering; and the more this diſtance is divided into ſeparate and diſtinct parts, the greater it appears to be. For this reaſon, diſtances upon uneven ſurfaces appear leſs than upon a plane: for the inequalities of the ſurfaces, ſuch as hills, and holes, and rivers, that lie low and out of ſight, either do not appear, or hinder the parts that lie behind them from appearing; and ſo the whole apparent diſtance is diminiſhed by the parts that do

Apparent place, &c. of objects.

not appear in it. This is the reaſon that the banks of a river appear contiguous to a diſtant eye, when the river is low and not ſeen.

219
Several fallacies of viſion explained.

Dr Porterfield very well explains ſeveral fallacies in viſion depending upon our miſtaking the diſtances of objects. Of this kind, he ſays, is the appearance of parallel lines, and long viſtas conſiſting of parallel rows of trees; for they ſeem to converge more and more as they are farther extended from the eye. The reaſon of this, he ſays, is becauſe the apparent magnitudes of their perpendicular intervals are perpetually diminiſhing, while, at the ſame time, we miſtake their diſtance. Hence we may ſee why, when two parallel rows of trees ſtand upon an aſcent, whereby the more remote parts appear farther off than they really are, becauſe the line that meaſures the length of the viſtas now appears under a greater angle than when it was horizontal, the trees, in ſuch a caſe, will ſeem to converge leſs, and ſometimes, inſtead of converging, they will be thought to diverge.

For the ſame reaſon that a long viſta appears to converge more and more the farther it is extended from the eye, the remoter parts of a horizontal walk or a long floor will appear to aſcend gradually; and objects placed upon it, the more remote they are the higher they will appear, till the laſt be ſeen on a level with the eye; whereas the ceiling of a long gallery appears to deſcend towards a horizontal line, drawn from the eye of the ſpectator. For this reaſon, alſo, the ſurface of the ſea, ſeen from an eminence, ſeems to riſe higher and higher the farther we look; and the upper parts of high buildings ſeem to ſtoop, or incline forwards over the eye below, becauſe they ſeem to approach towards a vertical line proceeding from the ſpectator's eye; ſo that ſtatues on the top of ſuch buildings, in order to appear upright, muſt recline, or bend backwards.

Our author alſo ſhows the reaſon why a windmill, ſeen from a great diſtance, is ſometimes imagined to move the contrary way from what it really does, by our taking the nearer end of the ſail for the more remote. The uncertainty we ſometimes find in the courſe of the motion of a branch of lighted candles, turned round at a diſtance, is owing, he ſays, to the ſame cauſe; as alſo our ſometimes miſtaking a convex for a concave ſurface, more eſpecially in viewing ſeals and impreſſions with a convex glaſs or a double microſcope; and laſtly, that, upon coming in a dark night into a ſtreet, in which there is but one row of lamps, we often miſtake the ſide of the ſtreet they are on.

Far more light was thrown upon this curious ſubject by M. Bouguer.

220
Great light thrown upon this ſubject by M. Bouguer.

The proper method of drawing the appearance of two rows of trees that ſhall appear parallel to the eye, is a problem which has exerciſed the ingenuity of ſeveral philoſophers and mathematicians. That the apparent magnitude of objects decreaſes with the angle under which they are ſeen, has always been acknowledged. It is alſo acknowledged, that it is only by cuſtom and experience that we learn to form a judgement both of magnitudes and diſtances. But in the application of theſe maxims to the above mentioned problem, all perſons, before M. Bouguer, made uſe of the real diſtance inſtead of the apparent one; by which only the mind can form its judgment. And it is manifeſt, that, if any circumſtances contribute to make the diſtance appear otherwiſe than it is in reality, the apparent magnitude of the object will be affected by it; for the ſame reaſon, that, if the magnitude be miſapprehended, the idea of the diſtance will vary.

Apparent place, &c. of objects.

For want of attending to this diſtinction, Tacquet pretended to demonſtrate, that nothing can give the idea of two parallel lines (rows of trees for inſtance) to an eye ſituated at one of their extremities, but two hyperbolical curves, turned the contrary way; and M. Varignon maintained, that in order to make a viſta appear of the ſame width, it muſt be made narrower, inſtead of wider, as it recedes from the eye.

M. Bouguer obſerves, that very great diſtances, and thoſe that are conſiderably leſs than they, make nearly the ſame impreſſion upon the eye. We, therefore, always imagine great diſtances to be leſs than they are; and for this reaſon the ground plan of a long viſta always appears to riſe. The viſual rays come in a determinate direction; but as we imagine that they terminate ſooner than they do, we neceſſarily conceive that the place from which they iſſue is elevated. Every large plane, therefore, as AB, (fig. 2.) viewed by an eye at O, will ſeem to lie in ſuch a direction as A*b*; and conſequently lines, in order to appear truly parallel on the plane AB, muſt be drawn ſo as that they would appear parallel on the plane A*d*, and be from thence projected to the plane AB.

Plate CCCLXV.

To determine the inclination of the apparent ground-plan A*d* to the true ground-plan AB, our ingenious author directs us to draw upon a piece of level ground two ſtraight lines of a ſufficient length (for which purpoſe lines faſtened to ſmall ſticks are very convenient), making an angle of 3 or 4 degrees with one another. Then a perſon, placing himſelf within the angle, with his back towards the angular point, muſt walk backwards and forwards till he can fancy the lines to be parallel. In this ſituation, a line drawn from the point of the angle through the place of his eye, will contain the ſame angle with the true ground-plan which this does with the apparent one.

M. Bouguer then ſhows other more geometrical methods of determining this inclination; and ſays; that by theſe means he has often found it to be 4 or 5 degrees, though ſometimes only 2 or 2½ degrees. The determination of this angle, he obſerves, is variable; depending upon the manner in which the ground is illuminated and the intenſity of the light. The colour of the ſoil is alſo not without its influence, as well as the particular conformation of the eye, by which it is more or leſs affected by the ſame degree of light, and alſo the part of the eye on which the object is painted. When, by a ſlight motion of his head, he contrived, that certain parts of the ſoil, the image of which fell towards the bottom of his eye, ſhould fall towards the top of the retina, he always thought that this apparent inclination became a little greater.

But what is very remarkable, and what he ſays he can aſſure his reader may be depended upon, is, that if he look towards a riſing ground, the difference between the apparent ground-plan and the true one will be much more conſiderable, ſo that they will ſometimes make an angle of 25 or 30 degrees. Of this he had made frequent obſervations. Mountains, he ſays, begin to be inacceſſible when their ſides make an angle from 35 to 37 degrees with the horizon, as then it is not poſſible to climb them but by means of ſtones or ſhrubs, to ſerve as ſteps to fix the feet on. In theſe caſes, both he and his companions always agreed that the apparent inclination of the ſide of the mountain was 60 or 70 degrees.

Plate CCCLXI

Theſe deceptions are repreſented in fig. 3. in which, when the ground-plan AM, or AN, is much inclined, the apparent ground-plan A*m*, or A*n*, makes a very large angle with it. On the contrary, if the ground dips below the level, the inclination of the apparent to the true ground-plan diminiſhes, till, at a certain degree of the ſlope, it becomes nothing at all; the two plans AP and A*p* being the ſame, ſo that parallel lines drawn upon them would always appear ſo. If the inclination below the horizon is carried beyond the ſituation AP, the error will increaſe; and what is very remarkable, it will be on the contrary ſide; the apparent plan A*r* being always below the true plan AR, ſo that if a perſon would draw upon the plan AR lines that ſhall appear parallel to the eye, they muſt be drawn converging, and not diverging, as is uſual on the level ground; becauſe they muſt be the projections of two lines imagined to be parallel, on the plan A*r*, which is more inclined to the horizon than AR.

Theſe remarks, he obſerves, are applicable to different planes expoſed to the eye at the ſame time. For if BH, fig. 4. be the front of a building, at the diſtance of AB from the eye, it will be reduced in appearance to the diſtance A*b*; and the front of the building will be *bh*, rather inclined towards the ſpectator, unleſs the diſtance be inconſiderable.

After making a great number of obſervations upon this ſubject, our author concludes, that when a man ſtands upon a level plane, it does not ſeem to riſe ſenſibly but at ſome diſtance from him. The apparent plane, therefore, has a curvature in it, at that diſtance, the form of which is not very eaſy to determine; ſo that a man ſtanding upon a level plane, of infinite extent, will imagine that he ſtands in the centre of a baſon. This is alſo, in ſome meaſure, the caſe with a perſon ſtanding upon the level of the ſea.

He concludes with obſerving, that there is no difficulty in drawing lines according to theſe rules, ſo as to have any given effect upon the eye, except when ſome parts of the proſpect are very near the ſpectator, and others very diſtant from him, becauſe, in this caſe, regard muſt be had to the conical or conoidal figure of a ſurface. A right line paſſing at a ſmall diſtance from the obſerver, and below the level of his eye, in that caſe almoſt always appears ſenſibly curved at a certain diſtance from the eye; and almoſt all figures in this caſe are ſubject to ſome complicated optical alteration to which the rules of perſpective have not as yet been extended. If a circle be drawn near our feet, and within that part of the ground which appears level to us, it will always appear to be a circle, and at a very conſiderable diſtance it will appear an ellipſe; but between theſe two ſituations, it will not appear to be either the one or the other, but will be like one of thoſe ovals of Deſcartes, which is more curved on one of its ſides than the other.

On theſe principles a parterre, which appears diſtorted when it is ſeen in a low ſituation, appears perfectly regular when it is viewed from a balcony or any other eminence. Still, however, the apparent irregularity takes place at a greater diſtance, while the part that is near the ſpectator is exempt from it. If AB, fig. 5. be the ground-plan, and A*a* be a perpendicular, under the eye, the higher it is ſituated, at O, to the greater diſtance will T, the place at which the plane begins to have an apparent aſcent along T*b*, be removed.

All the varieties that can occur with reſpect to the viſible motion of objects, are thus ſuccinctly ſummed up by Dr Porterfield under eleven heads.

1. An object moving very ſwiftly is not ſeen, unleſs it be very luminous. Thus a cannon ball is not ſeen if it is viewed tranſverſely: but if it be viewed according to the line it deſcribes, it may be ſeen, becauſe its picture continues long on the ſame place of the retina; which, therefore, receives a more ſenſible impreſſion from the object.

2. A live coal ſwung briſkly round in a circle appears a continued circle of fire, becauſe the impreſſions made on the retina by light, being of a vibrating, and conſequently of a laſting nature, do not preſently periſh, but continue till the coal performs its whole circuit, and returns again to its former place.

3. If two objects, unequally diſtant from the eye, move with equal velocity, the more remote one will appear the ſlower; or, if their celerities be proportional to their diſtances, they will appear equally ſwift.

4. If two objects, unequally diſtant from the eye, move with unequal velocities in the ſame direction, their apparent velocities are in a ratio compounded of the direct ratio of their true velocities, and the reciprocal one of their diſtances from the eye.

5. A viſible object moving with any velocity appears to be at reſt, if the ſpace deſcribed in the interval of one ſecond be imperceptible at the diſtance of the eye. Hence it is that a near object moving very ſlowly, as the index of a clock, or a remote one very ſwiftly, as a planet, ſeems to be at reſt.

6. An object moving with any degree of velocity will appear at reſt, if the ſpace it runs over in a ſecond of time be to its diſtance from the eye as 1 to 1400.

7. The eye proceeding ſtraight from one place to another, a lateral object, not too far off, whether on the right or left, will ſeem to move the contrary way.

8. The eye proceeding ſtraight from one place to another, and being ſenſible of its motion, diſtant objects will ſeem to move the ſame way, and with the ſame velocity. Thus, to a perſon running eaſtwards, the moon on his right hand appears to move the ſame way, and with equal ſwiftneſs; for, by reaſon of its diſtance, its image continues fixed upon the ſame place of the retina, from whence we imagine that the object moves along with the eye.

9. If the eye and the object move both the ſame way, only the eye much ſwifter than the object, the laſt will appear to go backwards.

10. If two or more objects move with the ſame velocity, and a third remain at reſt, the moveable ones will appear fixed, and the quieſcent in motion the

contrary way. Thus clouds moving very ſwiftly, their parts ſeem to preſerve their ſituation, and the moon to move the contrary way.

11. If the eye be moved with great velocity, lateral objects at reſt appear to move the contrary way. Thus to a perſon ſitting in a coach, and riding briſkly through a wood, the trees ſeem to retire the contrary way; and to people in a ſhip, &c. the ſhores ſeem to recede.

221
Dr Porterfield's account of objects appearing to move to a giddy perſon when he and they are both at reſt.

At the concluſion of theſe obſervations, our author endeavours to explain another phenomenon of motion, which, though very common and well known, had not, ſo far as he knew, been explained in a ſatisfactory manner. It is this: If a perſon turns ſwiftly round, without changing his place, all objects about will ſeem to move round in a circle the contrary way; and this deception continues not only while the perſon himſelf moves round, but, which is more ſurpriſing, it alſo continues for ſome time after he ceaſes to move, when the eye, as well as the object, is at abſolute reſt.

The reaſon why objects appear to move round the contrary way, when the eye turns round, is not ſo difficult to explain: for though, properly ſpeaking, motion is not ſeen, as not being in itſelf the immediate object of ſight; yet by the ſight we eaſily know when the image changes its place on the retina, and thence conclude that either the object, the eye, or both, are moved. But by the ſight alone we can never determine how far this motion belongs to the object, how far to the eye, or how far to both. If we imagine the eye at reſt, we aſcribe the whole motion to the object, though it be truly at reſt. If we imagine the object at reſt, we aſcribe the whole motion to the eye, though it belongs entirely to the object; and when the eye is in motion, though we are ſenſible of its motion, yet, if we do not imagine that it moves ſo ſwiftly as it really does, we aſcribe only a part of the motion to the eye, and the reſt of it we aſcribe to the object, though it be truly at reſt. This laſt, he ſays, is what happens in the preſent caſe, when the eye turns round; for though we are ſenſible of the motion of the eye, yet we do not apprehend that it moves ſo faſt as it really does; and therefore the bodies about appear to move the contrary way, as is agreeable to experience.

But the great difficulty ſtill remains, viz. Why, after the eye ceaſes to move, objects ſhould, for ſome time, ſtill appear to continue in motion, though their pictures on the retina be truly at reſt, and do not at all change their place. This, he imagined, proceeds from a miſtake we are in with reſpect to the eye, which, though it be abſolutely at reſt, we nevertheleſs conceive as moving the contrary way to that in which it moved before; from which miſtake, with reſpect to the motion of the eye, the objects at reſt will appear to move the ſame way which the eye is imagined to move; and, conſequently, will ſeem to continue their motion for ſome time after the eye is at reſt.

222
Dr Wells accounts for this phenomenon.
